

Corruption significantly increases the capital cost of power plants in developing contexts

7 **Abstract**

8 Emerging economies with rapidly growing population and energy demand, own some of the most
9 expensive power plants in the world. We hypothesized that corruption has a relationship with the
10 capital cost of power plants in developing countries such as Bangladesh. For this study, we analyzed
11 the capital cost of 61 operational and planned power plants in Bangladesh. Initial comparison study
12 revealed that the mean capital cost of a power plant in Bangladesh is twice than that of the global
13 average. Then, the statistical analysis revealed a significant correlation between corruption and the
14 cost of power plants, indicating that higher corruption leads to greater capital cost. The high up-front
15 cost can be a significant burden on the economy, at present and in the future, as most are financed
16 through international loans with extended repayment terms. There is, therefore, an urgent need for the
17 review of the procurement and due diligence process of establishing power plants, and for the
18 implementation of a more transparent system to mitigate adverse effects of corruption on
19 megaprojects.

20 **1 Introduction**

21 Bangladesh is the world's eighth most populous country of 161 million people with annual
22 population and GDP growth rates of 1.2% and 6.6% respectively (WB, 2016). While the population
23 grew linearly, electricity consumption per capita increased exponentially since 1970, as shown in
24 Figure 1A and G. The GDP-electricity elasticity of the country exhibits a strong linear relationship
25 ($R^2=0.989$); electricity consumption increased by 4.15 kWh/capita for every US\$ increase in
26 GDP/capita in 1971-2011 (Figure 2). Moreover, past research indicates a unidirectional causal
27 relationship is running from electricity consumption to investment and economic growth in
28 Bangladesh—implying that over time, increasing electricity consumption results in higher economic
29 growth (Masuduzzaman, 2012). Therefore, the government aimed towards giving access to electricity
30 all households by 2021 (BPDB, 2015). The causal relationship between economic growth and
31 electricity consumption illustrated in Figure 2 and available literature suggested that, as more people
32 get access to electricity, the demand of electric power may increase significantly as Bangladesh aims
33 at transition from a lower-middle-income to a middle-income country by 2021 (MoF, 2011) and
34 developed by 2040 (FE, 2015; Jalil & Islam, 2010). The required additional economic growth is
35 expected to result from the expansion and development of the energy-intensive manufacturing and
36 service sectors (ILO & ILS, 2013; Nath, 2012; ADB, 2016).

37 The power sector in Bangladesh underwent several significant restructurings since its humble
38 beginning at the turn of the 20th century. Electricity was provided only to the wealthy residents in the
39 capital with small power plants (Omprasad, 2016) but gradually shifted its focus towards serving
40 essential businesses and industries by 1947 (Ebinger, 2011). Post-independence evolution of the
41 power sector is illustrated in Figure 1, which commenced with the establishment of Bangladesh
42 Power Development Board (BPDB) and Rural Electrification Board (REB) in 1972 and 1977, to
43 foster economic development in urban and rural areas respectively (BPDB, 2017; BREB, 2016). In
44 light of increasing demand in divisional cities and the need for interconnection, East and West zones
45 were connected by a 230 kV transmission line in 1982 (Ebinger, 2011). Despite the expansion of the
46 grid, most of the population did not have access to uninterrupted electricity supply (Figure 1B).
47 Moreover, only 62.4% of the population has access to grid electricity in 2014 (WB, 2016).

48 National Energy Policy 1994 paved the way for deregulation to encourage broader participation in
49 power generation (Ebinger, 2011). Publicly-owned Rural Power Company Limited (RPCL) was set
50 up as the first independent power producer (IPP) in the same year (Mourshed, 2013). Privately
51 owned IPPs started operation in 1997, under the build-own-operate (BOO) model of public-private
52 partnership (PPP). The effects of increased generation can be seen in the economic growth in the
53 subsequent decades. The average GDP growth rate of 3.8% in the 1980s rose to 4.8%, 5.6%, 6.2% by
54 1990s, 2000s and mid-2010s respectively (Figure 1C). Further deregulation allowed the
55 establishment of rental power plants (RPPs) on 3- and 15-year contracts to meet the peak demand
56 (Figure 1E) (MoF, 2009).

57 <Insert Figure 1 about here>

58 Most RPPs are oil based that relies on imported petroleum as Bangladesh has insufficient oil reserve.
59 By increasing oil dependency (Mujeri, et al., 2014), the energy sector was exposed to the volatile
60 international oil market (Mourshed, 2013). Energy sector subsidies have escalated because of
61 growing import prices for fuels to encounter the accelerated energy demand (Mujeri, et al., 2014).
62 Moreover, the lack of adequate governance acted as an incentive for corruption to grow in the energy
63 sector of Bangladesh (Khan & Rasheduzzman, 2013; Ahmed, 2011; Khatun & Ahamad, 2013).
64 Public sector generation capacity has increased exponentially between 1970 and 1997. The growth in
65 the public sector slowed down when the private sector began supplementing generation in 1997
66 (Figure 1E and F). Majority of the increase since 1997 came from the private sector and the trend is
67 projected to continue towards an installed capacity of 33.7 GW by 2030 (JICA & TEPCO, 2011)
68 from 13.7 GW in 2017 (BPDB, 2017).

69 <Insert Figure 2 about here>

70 In the case of fuel types, increased oil-based RPPs have changed the generation fuel-mix within five
71 years of their expansion. Figure 1H illustrates that 80% of installed capacity in 2010 was based on
72 natural gas (hereafter gas only), which reduced to 68% in 2015 (MoF, 2010). Although the increase
73 in oil-based generation was suggested as short-term quick-fix to meet the burgeoning growth in
74 demand for electricity, the overall direction of generation fuel mix is sub-optimal. The 2010 Power
75 Sector Master Plan (PSMP2010) focuses on coal-based generation increase to a fuel mix of coal-gas-
76 others (50%-25%-25%) in 2030 (JICA & TEPCO, 2011), which is a significant departure from the
77 mix of gas-liquid fuel-renewables (54%-28%-8%) in 1980 (Figure 1D). Although the number of
78 privately owned power plants are five times in number than that of public ones, public sectors have
79 1.66 times greater installed capacity than that of the private counterpart (BPDB, 2017). Most of the
80 public generation capacity in Bangladesh is divided into four subsidiaries such as Ashuganj Power

81 Station Company Limited (APSCL), Electricity Generation Company of Bangladesh (EGCB), North-
82 West Power Generation Company Limited (NWPGL) and West Zone Power Distribution Company
83 Limited (WZPDCL). BPDB is the sole purchaser of the generated electricity, which is then
84 transmitted via the Power Grid Company of Bangladesh Limited (PGCB) and distributed by State-
85 owned area-based distribution companies. At present, bulk generation is centralized and mostly fossil
86 fuel based. However, there are decentralized renewable power generation projects such as mini-grid,
87 solar home systems (SHS) have been operational and under development for off-grid rural and
88 remote areas. The government have targeted to generate 10% of the total electricity from renewable
89 resources by 2021 (IDCOL, 2017). Although, IDCOL is aiming towards total SHS installed capacity
90 of 200 MW by 2021, and installing 50 solar mini-grid by 2018 (IDCOL, 2017), the cumulative
91 capacity of the off-grid generation will contribute very little to the electricity supply. Bangladesh
92 takes a considerable amount of loans from national and international funding bodies for establishing
93 power plants. Therefore, they would need to borrow a significant amount of loan to construct the
94 substantial number of stations to achieve a 20 GW of additional installed capacity by 2030 than that
95 of 2017 (BPDB, 2017; JICA & TEPCO, 2011). With considerable capital costs involved and
96 previous evidence of corruption in the energy sector (Khan & Rasheduzzman, 2013; Ruth, 2002) as
97 well as in public procurement (Mahmood, 2010), the utilization of massive amount of money can
98 prove to be a significant concern in Bangladesh.

99 There have been different studies on the relationship between corruption and cost of big public
100 projects. Study on Italian high-speed railways megaprojects demonstrated that corruption worsens
101 both cost and temporal performance (Locatelli, et al., 2017). This study also identified the project
102 contexts such as the discretionary power of officials, economic rents of policy/decision makers and
103 weak institutions would make a country ideal for corruption. Another study demonstrated that capital
104 cost of IPPs selected without competitive bidding was 44-56% higher than that of with competitive
105 bidding in developing countries including Bangladesh (Phadke, 2009). However, only two projects
106 with competitive bidding (4.87% of the total projects analysed) were considered in the case of
107 Bangladesh. Therefore, the result was generic for developing countries, and the conclusion was not
108 robust for Bangladesh. In another research, the Malaysian context was analysed to find the reasons
109 behind corruption were an abuse of power, opportunity and moral compromise within the
110 government officials (Othman, et al., 2014). Also, different studies suggest that the ongoing
111 corruption can be controlled via random and regular supervision, severe punishment and prosecution
112 of corrupt personnel, and anti-corruption awareness development (Zou, 2006; De Chiara & Livio,
113 2017). Although the literature suggests that government personals are mostly responsible for active
114 corruption by asking bribes, the private sector can also contribute by acting as passive corruption
115 through approaching bureaucrats by offering bribes (Capasso & Santoro, 2017). However, there is a
116 gap in the literature regarding studies on cost evolution of energy sector in developing economies
117 such as Bangladesh, and their relation to corruption, due to the lack of political transparency and
118 data. There are two objectives of this paper. Initially, to investigate the capital cost of establishing
119 various power plants in Bangladesh and compare with other countries, regions and world, to find any
120 differences. Furthermore, to understand the reason behind the differences, we hypothesized that
121 corruption might have influenced the capital cost of power plants in Bangladesh. The correlation
122 between the capital cost of the power plants and Corruption Perceptions Index (CPI) of Bangladesh
123 was examined to test the hypothesis.

124 **2 Methodology**

125 The study was conducted in three stages. First, annual (BPDB, 2008; BPDB, 2009; BPDB, 2010;
126 BPDB, 2011; BPDB, 2012; BPDB, 2013; BPDB, 2014; BPDB, 2015; KPCL, 2014), project

127 (APSCCL, 2015; CPGCBL, 2015; EGCBL, 2015; APSCCL, 2015) and financial aid reports (IDCOL,
128 2015; WB, 2017) from national bodies and international organizations were reviewed to develop a
129 capital cost database of power plants in Bangladesh. Capital cost refers to all the expenses incurred
130 before a plant becomes operational and comprises the cost associated with the acquisition of land;
131 permits and legal matters; plant equipment and construction; financing; and the commissioning of the
132 plant. Independent scrutiny of public expenditure does not feature strongly in Bangladesh's
133 governance structure. Hence, the total capital cost or the breakdown of the capital cost of all the
134 operational power plants is not publicly available. There were 100 public power plants in January
135 2016, of which 96 were operational (BPDB, 2017). We collected primary data such as installed
136 capacity, commissioning year, fuel and owner of 165 units from 113 public and private operational
137 Bangladeshi power plants in January 2016. The number of public and private owned units were 80
138 (6968 MW) and 85 (5566 MW) respectively. Among the operational units, ninety-five utilize gas,
139 and seven are dual fuel type, of which four can use gas and heavy fuel oil (HFO). The rest of the
140 three dual-fuel plants utilize high-speed diesel (HSD) and gas. Moreover, only HFO and HSD based
141 units were 32 and 23 respectively. Two units were coal-based, and four units were hydroelectric.
142 Also, there was a 500 MW interconnection with India in Khulna. Due to data constraints, the capital
143 cost of 61 fossils (gas, coal and petroleum) and renewable (nuclear, hydro, the wind and solar) power
144 plants in Bangladesh commissioned since 1962 and planned up to 2030, were collected (Table 1). Of
145 the 61 plants, 34 are operational, and 27 are under construction, repair or future planned. The study
146 had to test the hypothesis with lower data constrain and bias generated by it because of unavailability
147 of cost data. The government has started to provide cost data since 2007 through the annual reports
148 (BPDB, 2017). With more data and transparency in the future, the studies regarding cost can be
149 improved to make the power plants more cost-effective.

150 Among the analyzed 61 power plant units, gas, HFO/HSD/dual fuel, coal, nuclear and renewable
151 based were 34, 17, four, one and five respectively. Moreover, 48 are public, and thirteen are privately
152 operated. All the future and under-construction power plants are government owned. Among the nine
153 analyzed dual fuel power plant units, three utilize HFO and gas, of which two are public, and one is
154 privately owned. Six dual fuel power plant units use HSD and gas, of which one is private, and five
155 are publicly owned. There are only nine HFO based power plant units, of which two are planned for
156 future and rest of them are operational. All the HFO based functional power plants are privately
157 owned. In the case of coal-based power plants units, only two are functional, and three are planned
158 for future, and all of them are publicly owned. Similarly, all the renewable power plants are
159 government owned, of which one is the Kaptai hydroelectric plant (5 units) and two small solar
160 energy plants. The only planned nuclear power plant (Rooppur 1 and 2) would be publicly owned
161 too. Three phases (Unit 1 and 2; Unit 3; Unit 4 and 5) of Kaptai hydroelectric power plant was
162 considered separately because three stages had different cost individually. Among the coal power
163 generation technologies, domestic coal-fueled subcritical plants were built in Barapukuria. Moreover,
164 two new ultra-supercritical plants are under construction which would operate with imported coal.
165 Cost per installed capacity in kW in a specific year of construction of the power plant was calculated
166 and converted to the US dollar (USD) equivalent using the currency exchange rate with Bangladeshi
167 Taka (BDT) on December 31 of the same year, obtained from Bangladesh Bank (BB, 2016). In cases
168 where a power plant is going to be built after 2015, the cost was converted to 2015 USD using BDT
169 to USD exchange rate on December 31, 2015. Then the historical cost data was converted using
170 Consumer Price Index (Coinnews, 2016) of 2015 USD so that all cost can be compared on the 2015
171 USD basis.

172 <Insert Table 1 about here>

173 Second, country- and region-wise capital costs of power plants for the same technology used in
 174 Bangladesh were collected from the International Energy Agency's (IEA) World Energy Investment
 175 Outlook 2014 (IEA, 2014) for USA, Japan, Russia, China, India, Brazil, Europe, the Middle East and
 176 Africa. There were three data points for all the countries for 2012, 2020, and 2035. Data for Sri
 177 Lanka were collected from 'Long-Term Generation Expansion Planning Studies 2015- 2034' for
 178 2015 (Samarasekara & Silva, 2015). In the case of USA, further data on cost and performance of
 179 power generation technologies were collected from National Renewable Energy Laboratory (NREL)
 180 to augment the IEA data (NREL, 2012). There were ten data points for the cost data from NREL for
 181 2008, 2010, 2015, 2020, 2025, 2030, 2035, 2040, 2045 and 2050. Also, CPI score between 1995 and
 182 2016 was collected from Transparency International (TI) (TI, 2017).

183 Third, the average cost of power plants in Bangladesh was compared with that of the identified
 184 countries, regions and the World using 2015 as a base year. The evolution of cost was also analysed
 185 for both public and private sectors in Bangladesh. Pearson's test was conducted at normalised capital
 186 cost and CPI score to examine the effect of corruption on power plant capital cost in Bangladesh. CPI
 187 data is available only from 1995, which reduced the sample size down to 31 for the correlation study.
 188 Among the collected cost data, power plants commissioned from 2004 to 2015 were considered.
 189 There were no cost data available for any power plants established between 1995 and 2003. There
 190 were also some cost data for power plants built before 1995. As the CPI index started in 1995, the
 191 cost data before that was not considered for the correlation study. As the sample size is less than 50,
 192 Shapiro-Wilk and Kolmogorov-Smirnov test of normality were conducted (Ghasemi & Zahediasl,
 193 2012) and Table 2 indicated that the distribution of interval data was normal, supporting the selection
 194 of Pearson's test.

195 <Insert Table 2 about here>

196 **3 Discussion**

197 Power generation technology is the critical factor for the variation in the capital cost. For this study,
 198 initially, capital cost of various public and private power plants in Bangladesh with varied
 199 technologies such as gas turbines (GT) and combined-cycle power plant (CCPP); subcritical and
 200 ultra-supercritical plants; hydroelectric; nuclear and solar PV plants were compared with the world
 201 average, to find out the cost difference. When the cost of GT and steam turbines (ST) are compared,
 202 public power plants (hereafter plants) in Bangladesh are found to be approximately 2.2 times more
 203 expensive than that of the world mean (Figure 3A). The cost of public GTs is even higher, around 1.5
 204 times than the private plants in Bangladesh. In the case of CCPP, public plants' mean is 1.2 and 1.7
 205 times more expensive than that of the world mean and the private plants' mean respectively (Table
 206 3).

207 The private CCPP with an average cost of \$540 /kW, where publicly owned ones ranged from \$853-
 208 3005 /kW (Figure 3B). Moreover, future planned public CCPP cost range from \$554-1612 /kW.
 209 Therefore, public CCPP in Bangladesh can be built with as low-cost as China (\$568 /kW between
 210 2012 and 2020) to 19% greater than that of the highest cost of USA (\$1358 /kW between 2015 and
 211 2020). The difference between lowest and highest capital cost of CCPP (going to be commissioned in
 212 2017) is \$1058 /kW, the equivalent of constructing almost two CCPP plants in China. Cost difference
 213 can happen depending on the installed capacity. From long-term generation expansion planning study
 214 of Sri Lanka, two separate CCPP cost difference was \$202 /kW depending on the installed capacity.
 215 The capital cost of CCPP-Auto Diesel of 144 and 288 MW was \$853 and \$1055 /kW respectively in
 216 Sri Lanka (Samarasekara & Silva, 2015), which means higher installed capacity may reduce cost.

217 However, in the case of Bangladesh, Siddhirganj 335 MW and Bibiana (South) 383 MW CCPP plant
218 would cost \$1612 /kW and \$873 /kW respectively (operational by 2017). Though Bibiana (South)
219 has 48 MW higher installed capacity than that of the Siddhirganj, it would cost approximately half.
220 On the other hand in the private sector, Meghnaghat 450 MW CCPP (Unit 2) was constructed with
221 \$560 /kW in 2014.

222 Figure 3C and D compares the cost of coal power plants. The subcritical coal plant, capital cost range
223 from \$1245-\$1923 /kW, which is higher than the expense of the USA in the upper bound, and Africa
224 in lower bound. However, the cost of the proposed ultra-supercritical power plant is going to be
225 highest compared to the rest of the world (Figure 3D).

226 <Insert Figure 3 about here>

227 In the case of renewable energy, Bangladesh has been utilizing hydroelectricity from Kaptai power
228 plant since 1962, making it the oldest active power plant in Bangladesh with a capital cost of
229 \$6408 /kW for Unit 1 and 2, and parts of Unit 3. Capital cost reduced with the construction of Unit 3
230 in 1982, from \$6408 /kW to \$543 /kW (Figure 4B). Unit 3 was partially built during the construction
231 of Unit 1 and 2 in 1962, which reduced the capital cost of completion of Unit 3 in 1982. However,
232 the capital cost for Unit 4 and 5 was \$1075 /kW, which was constructed in 1988. Unit 4 and 5 were
233 constructed in an already established infrastructure with facilities such as dam, reservoir during the
234 construction of Unit 1, 2 and 3. Therefore, Unit 4 and 5 had higher capital cost than that of Unit 3.
235 While comparing the capital cost of Bangladeshi hydroelectric plants with the world, the cost
236 reported for other countries were suggested for the construction of new plants.

237 Currently, Bangladesh has small-scale solar home systems in households, but no significant
238 commercial, operational project. Two large solar PV plants are going to be constructed in 2016-17
239 with an installed capacity of 5 and 7 MW costing \$4906 /kW and \$2391 /kW respectively (Figure
240 4A). Despite the continuing descending trend in cost, one is costing higher than that of the highest in
241 the world for that year. Also, it is not clear why the difference in cost would be \$2515 /kW for just
242 2 MW, almost two times more than the cost of establishing similar technology power plant in China
243 in 2020.

244 In the case of nuclear power plants, the planned power plant in Bangladesh would be established with
245 the assistance from Russia in 2024-2025. However, the capital cost would be 1.45 times than that of
246 Russia and almost equivalent to Japan (Figure 4C).

247 <Insert Figure 4 about here>

248 Although power plants cost more in Bangladesh, the public plants are significantly more expensive
249 than the private ones, indicating that there may as well be other factors related to public sector
250 governance in play (Table 3). Further studies may reveal other factors such as political instability,
251 inefficient project management leading to construction delays and eventual increase in cost.
252 However, the deep-rooted and widespread corruption culture could have a higher impact on the
253 capital cost of the power plants, which needs further investigation with more data.

254 <Insert Table 3 about here>

255 3.1 Cost evolution

256 The cost evolution in Bangladeshi public and private plants do not follow the same trend. The cost of
257 most of the power generation technology in the world reduces with time (Neij, 2008). However, in
258 the Bangladeshi public plants, the cost appears to be increasing (Figure 5). Among the operational
259 power plants, GT, ST and CCPP have been generating the most of electricity in Bangladesh in the
260 last three decades in both public and private sectors. For the cost evolution analysis, the relatively
261 new or less utilized technologies (subcritical, ultra-supercritical and hydro) are not considered. Solar
262 PV, nuclear are new technologies compared to CCPP or GT in Bangladesh. The capital cost trend of
263 CCPP is following a second order polynomial and augmenting after 2010. In the case of the similar
264 technology, the private sector is showing a linear descending trend with only two data points.
265 Establishing cost of public GT/ST trend is third order polynomial and increasing after 2014.
266 However, private power plants with similar technology, demonstrating a second order polynomial
267 trend with a reduction in cost.

268 <Insert Figure 5 about here>

269 Independent-samples T-test was conducted to compare the capital cost in public and private owned
270 power plants. The cost of GT/ST and CCPP technologies were considered for the tests. In the case of
271 GT/ST, there was a significant difference in the capital cost of public ($M=1226.09$, $SD=360.62$) and
272 private ($M=751.68$, $SD=108.80$) owned power plants; $t(11.97)=4.16$, $p=0.001$. These results suggest
273 that GT/ST power plant ownership depending on being public and private influences its capital cost.
274 The test results suggest that public power plants have higher capital cost. In the case of CCPP, there
275 was not a significant difference in the capital cost of public ($M=1075.33$, $SD=263.21$) and private
276 ($M=704$, $SD=203.60$) owned power plants; $t(19)=1.92$, $p=0.070$. These results suggest that CCPP
277 power plant ownership depending on being public and private does not influence its capital cost.
278 However, the private CCPP power plants number was only two. With more data points in the future,
279 this analysis may be improved.

280 3.2 Corruption

281 Several reports and articles suggested that there has been significant evidence of corruption in
282 electricity generation projects and operations, as well as in distribution system in Bangladesh (Khan
283 & Rasheduzzman, 2013; TIB, 2016; Khan, 2007; Kenny, 2007; D'costa, 2012; IBP, 2012; Ruth,
284 2002; Hossain & Tamim, 2005/06). The measurement of corruption is complicated as it depends on
285 complex variables (Galtung, 2006). Therefore, no single source or polling method has yet been
286 developed that can provide a convincing methodology (Lambsdorff, 2006). Transparency
287 International started CPI score for different countries in 1995 to put the issue of corruption on the
288 international policy agenda (TI, 2017). For this study, CPI score for Bangladesh was adopted to be
289 analysed with the capital cost of power plants in the same year to examine the effect of corruption on
290 cost evolution. Before 2012, CPI scores were ranked 0-10. However, the scale was amended in 2012
291 to the range of 0-100, to demonstrate the better effect of corruption on the economy of a country (TI,
292 2012). The CPI scores before 2012 were converted to 0-100 scale by multiplying 10 with the scores
293 to compare the data from 2004-16. Higher CPI score is interpreted as lower corruption, which may
294 result in reduced capital cost and vice versa (Figure 6A&B). Only 42 public and private power plants
295 (among studied 61) cost data, which were built within 2004-16, were found and analyzed in this
296 correlation study. The cost data scarcity worked as a limitation in rendering a detailed relationship.
297 With increased data available in the future, the correlation may improve. Independent-samples T-test
298 was conducted to compare the capital cost in public and private owned power plants. There was a
299 significant difference in the capital cost of public ($M=1156.20$, $SD=332.40$) and private ($M=734.26$,
300 $SD=118.29$) owned power plants; $t(40)=4.09$, $p=0.000$. These results suggest that being public and

301 private owned influences its capital cost. The test results suggest that public power plants have higher
302 capital cost.

303 <Insert Figure 6 about here>

304 To assess the relationship between the CPI score and the capital cost of power plants in Bangladesh,
305 Pearson's test for normally distributed interval data was conducted. There was a negative correlation
306 between the two variables, $r = -0.477$, $n = 42$, $p = 0.001$ (Table 4). Figure 7 summarizes the results
307 and demonstrated that corruption in Bangladesh is negatively related to a capital cost of power plants
308 with $R^2=0.32$ for annual CPI scores. Overall, there was a strong, negative correlation between
309 corruption and capital cost of power plants. Decreases in corruption (increase in annual CPI score)
310 were correlated with increased capital cost of power plants. Corruption is a continual socio-economic
311 phenomenon traversing through years from megaproject construction and operation. CPI score
312 represents an annual performance of a country. Whereas the power plant megaproject constructions
313 usually go on for 2-7 years (GoB, 2015). Furthermore to the Pearson's correlation test between
314 annual CPI score and capital costs, additional correlation study was undertaken in this research to
315 explore the relationship of the cost with biannual, triannual and quadrennial average CPI scores. The
316 main objective of the study was to examine the correlation between different temporal CPI scores and
317 capital costs. Table 4 summarizes the results. Figure 7 illustrated that the correlation R^2 value was
318 better between the biannual CPI score and capital cost. However, the Pearson's correlation test
319 showed that the best relationship was between the annual CPI scores and capital costs as the p-value
320 was the lowest (Table 4).

321 <Insert Table 4 about here>

322 <Insert Figure 7 about here>

323 The upper and lower limits of cost reduction per CPI score increase were \$116.94 /kW and
324 \$45.47 /kW respectively. In some cases, the capital cost of public plants was two times higher than
325 that of the private ones for the similar technology and time frame. Therefore, Bangladesh can reduce
326 their cost of establishing power plants by reducing corruption. The power plant projects are
327 expensive, and the government takes 66-94% (GoB, 2015) of the total cost of loans from banks and
328 aid organisations such as World Bank, Asian Development Bank. Higher capital cost means a more
329 significant loan from funding bodies, which the government have to repay in the future from the
330 revenues. Larger repayment can put pressure on the economy and people.

331 One of the reasons behind this significant corruption was the lack of governance in the energy sector.
332 Implementing 'Quick Enhancement of Electricity and Energy Supply (Special Provisions) Act, 2010'
333 enabled the government and responsible departments with authority to take rapid energy
334 development initiatives while bypassing the 2006 public procurement law, with easy and quick
335 procurement procedure for investing in the energy sector outside the bar of jurisdiction of the court
336 (GoB, 2016). Laws such as 'Quick Enhancement of Electricity and Energy Supply (Special
337 Provisions) Act, 2010' raised significant concern regarding transparency allowing enhanced scope
338 for corruption among the donors (Choudhury, et al., 2010). The findings of this study suggest that the
339 corruption may have influenced the higher cost of power plants in the past and increased after the
340 implementation of the special provisions act (2010).

341 **4 Conclusion**

342 As a rapidly developing economy, Bangladesh has been establishing and will continue to build more
343 power plants to support the growing demand for electricity. Literature suggested that there is a lack
344 of research on the cost analysis of the rapidly growing energy sector in Bangladesh; partially because
345 of the data inadequacy and lack of transparency in the government. Initially, a cost databased was
346 compiled from different resources for this study. For analyzing the cost of installing power plants in
347 Bangladesh, the cost (public and private) data were compared with the world. The results
348 demonstrated an intriguing aspect of a rapidly developing economy. Most of the public plants
349 showed higher capital cost compared to the world average. Also, the cost of similar power generation
350 technologies in private and public sector has a significant difference in Bangladesh. On top of the
351 higher capital cost, the cost evolution demonstrated that cost of establishing public power plants is
352 augmenting with time, whereas its opposite in private sector as well as in the world. In the case of
353 expanding cost, this study showed a significant correlation between corruption and higher cost of
354 power plants. Higher corruption may increase the cost of a power plant in a developing context such
355 as Bangladesh.

356 This study renders the opportunity to focus on the amendable condition of corruption within the
357 governmental system to reduce the cost of establishing public power plants in Bangladesh. The
358 government should implement more transparent and supervised system for establishing power plants
359 to reduce the adverse influences of corruption on the megaprojects. Otherwise, there is a possibility
360 the expensive power plants would become into 'white elephant' projects (Ross & Staw, 1993; Lewis
361 & Williams, 1985), where the output is smaller than that of investment. The higher cost would
362 impose an additional burden on the future economy.

(C) Coal: Subcritical

(D) Coal: Ultra-supercritical

Figure 3. Capital cost comparison among fossil fuelled power plants from the world with Bangladesh. In the case of GT/ST and CCPP, Bangladeshi public power plant's mean capital cost is higher than that of the mean of private and world counterparts. Surprisingly, private power plant's mean capital cost was lower than the world mean for CCPP. Subcritical coal plant means capital cost is slightly higher than that of global mean. However, ultra-supercritical mean capital cost of Bangladesh would be significantly greater than the world mean.

Figure 4. Capital cost comparison among nuclear and renewable power plants from different country/regions with Bangladesh. In the case of solar PV plants, mean capital cost of Bangladesh is lower than the world mean. However, the installed capacity is only 12 MW. Mean capital cost for hydroelectric plants is also lower than that of global mean capital cost. The reason behind this lower cost is the later units were in the same plant side, which reduced the ancillary cost. For nuclear only one plant is going to be built in Bangladesh by 2030 and its cost would be significantly higher than that of the world mean capital cost.

Figure 5. Cost evolution of different power generation technologies. In the case of coal, one subcritical power plants and two future ultra-supercritical ones not sufficient to see the cost evolution. For hydroelectric, solar PV and nuclear, the power plant numbers are insufficient for analysis of learning rate or cost evolution. Under these circumstances, highly utilized technologies such as gas turbine/engine and CCPP for public and private power plants were analyzed for cost evolution.

(B)

Figure 6. (A) Average capital cost (2004-2016) and (B) CPI score (2004-2016). Chart 'B' is demonstrating that CPI index is not gradually reducing. Moreover, the average capital cost of power plants is related to the change of CPI score. Here, higher CPI score means lower corruption.

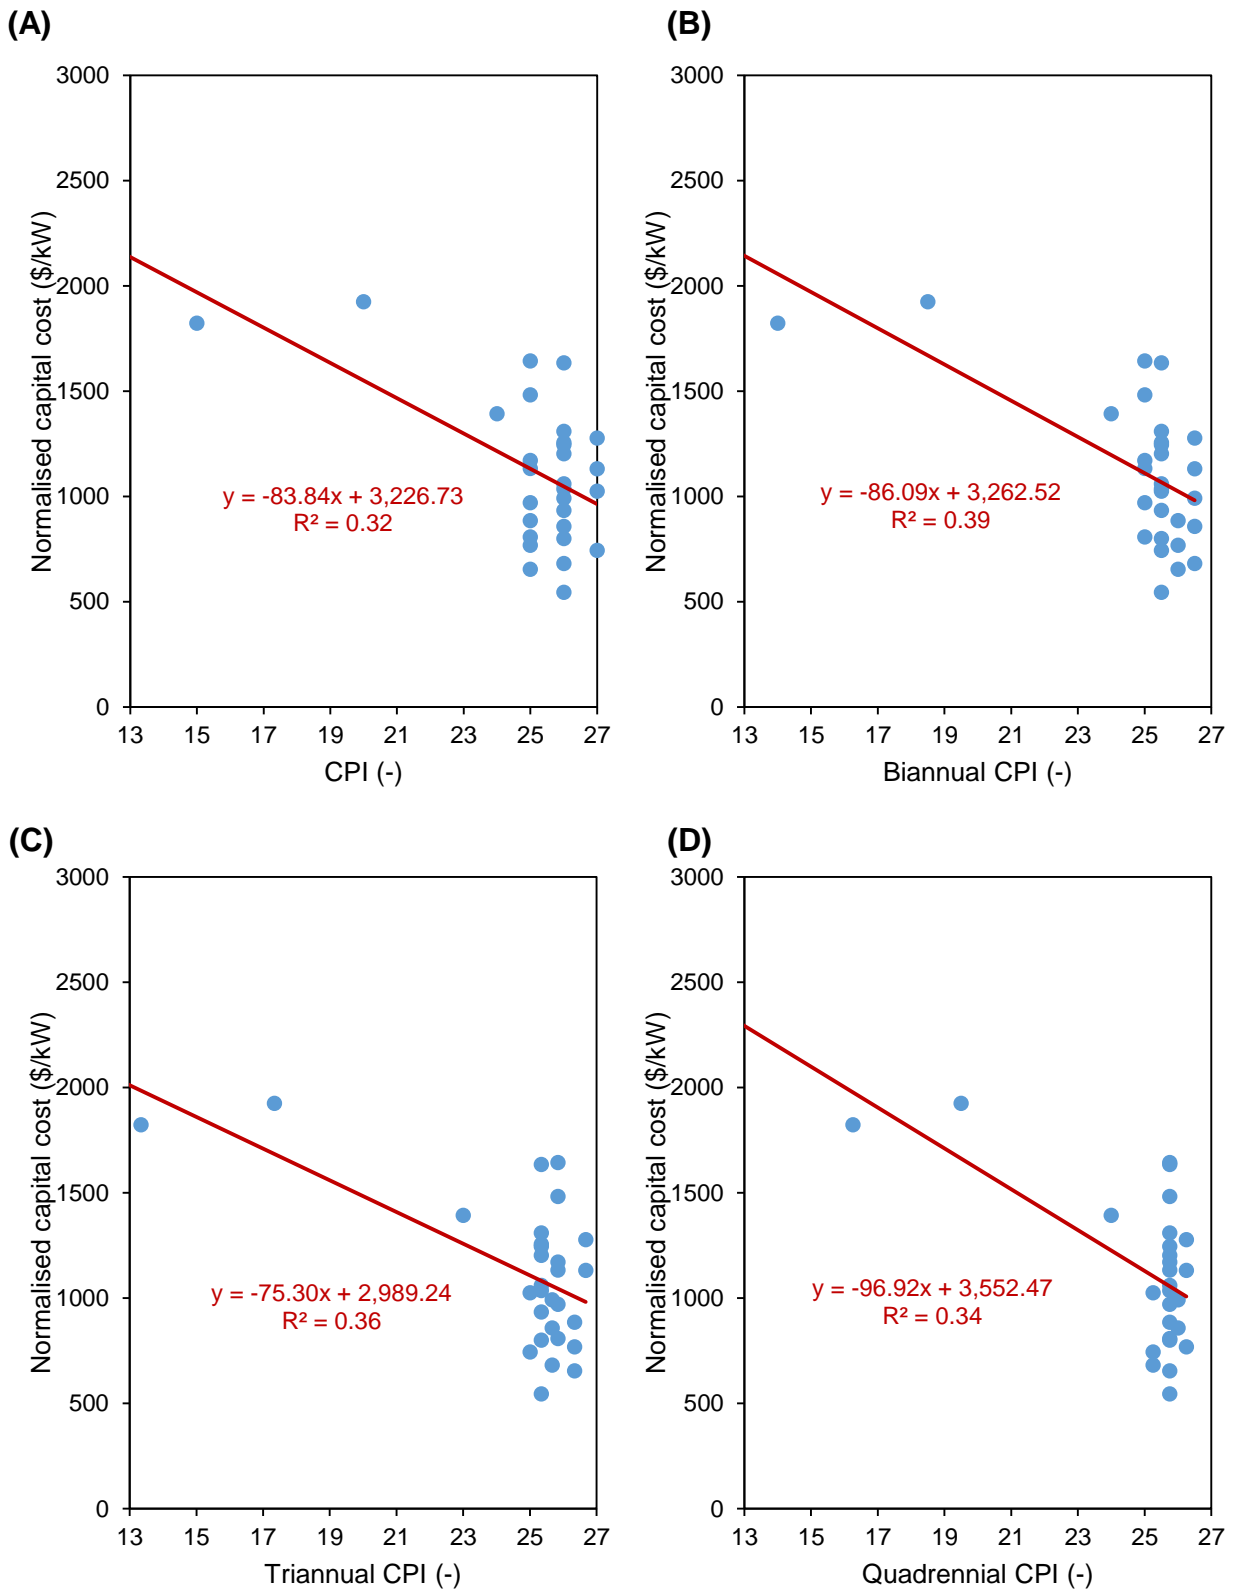

Figure 7. Corruption vs. capital cost analysis for Bangladeshi power plants; (A) Normalized capital cost vs. average annual CPI scores, (B) Normalized capital cost vs. average biannual CPI scores, (C) Normalized capital cost vs. average triannual CPI scores, and (D) Normalized capital cost vs. average quadrennial CPI scores.
