Objective: Restricted and repetitive pattern of behaviours (RRB) are a cardinal feature of autism spectrum disorder (ASD), but there remains uncertainty about how these diverse behaviours vary according to individual characteristics. This study provided the largest exploration to date of the relationship between Repetitive Motor Behaviours, Rigidity/Insistence on Sameness and Circumscribed Interests with other individual characteristics in newly diagnosed individuals with ASD.

Method: Participants (N= 3647; 17.7% females; Mage= 6.6 years [SD= 4.7]) were part of the Western Australian (WA) Register for ASD, an independent, prospective collection of demographic and diagnostic data of newly diagnosed cases of ASD in WA. Diagnosticians rated each of the DSM-IV-TR criteria on a 4-point Likert severity scale and here we focused on the Repetitive Motor Behaviours, Insistence on Sameness and Circumscribed Interests symptoms.

Results: The associations between RRB domains, indexed by Kendall's Tau, were weak, ranging from non-significant 0.003 for both Circumscribed Interests and Repetitive Motor Behaviours to significant 0.20 for Insistence on Sameness and Repetitive Motor Behaviours. Older age at diagnosis was significantly associated with lower Circumscribed Interests and significantly associated with higher Insistence on Sameness and Repetitive Motor Behaviours. Male sex was significantly associated with higher Repetitive Motor Behaviours but not Insistence on Sameness or Circumscribed Interests. Higher social impairments were a significant predictor of higher severity of only Circumscribed Interests but did not significantly predict other two domains.

Conclusion: The pattern of associations identified in this study provides suggestive evidence for the distinctiveness of Repetitive Motor Behaviours, Insistence on Sameness, and Circumscribed Interests, suggesting the potential utility of RRB domains for stratifying the

1 larger ASD population into smaller, more phenotypically homogeneous subgroups that can
2 help to facilitate efforts to understand diverse ASD etiology and inform design of future
3 interventions.

4 **Key Words:** repetitive behaviours; autism; social and communication impairments.

1 Uljarević et al., 2014) have most consistently identified two factor structure encompassing
2 Repetitive Motor Behaviours (RMB) and Insistence on Sameness (IS). RMB and Insistence
3 on Sameness domains map well onto ‘lower-order’ and ‘higher-order’ domains proposed by
4 Prior and Macmillan (1973) and later Turner (1999) based on clinical observations and a
5 developmental approach. It has been pointed out, however, that these domains, in particular
6 Insistence on Sameness, might be too broad, potentially masking the existence of other
7 distinct RRB domains (Leekam et al., 2011). Indeed, several studies have identified the
8 existence of a factor labeled as restricted or circumscribed interests (CI) (Bishop et al., 2013;
9 Honey et al., 2008; Lam et al., 2008). Repetitive Motor Behaviours, IS, and Circumscribed
10 Interests factors largely align with the RRB categories of adherence to routines, resistance to
11 change, repetitive movements, and intense and restrictive interests suggested by international
12 classification systems.

13 An alternative method to factor analytic approaches in establishing valid, clinically
14 meaningful, and independent RRB domains is to explore how these symptoms may vary
15 according to social and communication aspects of ASD phenotype and factors such as
16 chronological age (CA), sex, cognitive ability, executive functioning and/or co-occurring
17 conditions (Leekam et al., 2011). Despite the lack of long-term longitudinal studies,
18 preliminary findings suggest that while the Repetitive Motor Behaviours domain is more
19 prevalent and intense during early years, with subsequent waning throughout childhood
20 (Richler et al., 2010; Esbensen et al., 2009; Harrop et al., 2014), in contrast, Circumscribed
21 Interests and Insistence on Sameness domains, rarely observed at 2 years of age, increase
22 gradually throughout early childhood, and remain relatively stable during later childhood and
23 adolescence (Richler et al., 2010; South et al., 2005). Cross-sectional correlational studies
24 have yielded inconsistent results. While the Repetitive Motor Behaviours domain has been
25 reported to be negatively correlated with CA and IQ (Bishop et al., 2013; Cuccaro et al.,

1 2003), and the Insistence on Sameness and Circumscribed Interests domains positively
2 associated with CA and IQ (Bishop, Richler, & Lord, 2006; Bishop et al., 2013) other studies
3 did not report significant links (Hus et al., 2007; Lam et al., 2008; South et al., 2005).
4 Similarly inconsistent findings have been reported in terms of associations between RRB
5 domains with sex and social and communication impairments. Kim and Lord (2010) found
6 higher RMB levels in females, and several studies reported higher Circumscribed Interests
7 among males (Frazer & Hardan, 2017; Hiller, Young, & Weber, 2014; Knutsen et al., 2019),
8 however, other studies suggested no sex differences for Repetitive Motor Behaviours,
9 Insistence on Sameness, or Circumscribed Interests domains (Hus et al., 2007; Lam et al.,
10 2008; Sutherland et al., 2017). Frequency and severity of both Repetitive Motor Behaviours
11 (Hus et al., 2007; Lam et al., 2008; Szatmari et al., 2008) and Insistence on Sameness (Canon
12 et al., 2010; Lam et al., 2008; Richler et al., 2010) factors have been found to be associated
13 with more frequent and severe social and communication impairments, but non-significant
14 (Harrop et al., 2014) and even negative relationships (Hus et al., 2007; Richler et al., 2010)
15 have also been reported.

16 As can be seen from the overview presented above, it has proven difficult to establish
17 whether Repetitive Motor Behaviours, Insistence on Sameness, and Circumscribed Interests
18 factors are indeed related to other phenotypic aspects of ASD in a distinct way. It might then
19 be suggested that these domains are neither valid nor functionally distinct. However, this
20 conclusion would be premature, as inconsistent findings can also be ascribed to a number of
21 methodological limitations of previous studies. Firstly, the majority of studies that combined
22 factor analysis with exploring the pattern of association with other variables had small sample
23 sizes (majority had $N < 340$). This is a significant issue given the vast heterogeneity of ASD,
24 and given that studies differed widely in terms of characteristics of participants, with some
25 studies focusing on very young children and other studies including individuals with a very

1 wide chronological age range and also variable IQ level. Secondly, previous studies have not
2 considered in great detail how the presence of co-morbidities influenced the results. In
3 particular, it has been reported that co-occurrence of attention hyperactivity disorder (ADHD)
4 and ASD is associated with more severe impairments in executive functioning (Craig et al.,
5 2016) and reward processing (Dichter et al., 2012) each of which have been associated with
6 IS and Circumscribed Interests respectively (Uljarević et al., 2017a; Kohls et al., 2018).

7 Firm findings in large, well characterized, heterogeneous cohorts are essential in order
8 to advance the ASD research agenda (Amaral et al., 2017). Therefore, the current study
9 aimed to enhance our understanding of RRB by utilizing a unique repository of clinical data
10 from the Western Australian (WA) Register for Autism Spectrum Disorders (WA ASD)—a
11 long-term prospective, state-wide register of newly diagnosed cases of ASD. The WA ASD
12 Register contains data on the severity of the ASD DSM criteria, therefore collection of
13 information on the Repetitive Motor Behaviours, Insistence on Sameness and Circumscribed
14 Interests RRB domains that have been, as reviewed above, identified most consistently across
15 the factor analyses as the main RRB subtypes. The WA ASD register also collects data on
16 IQ, and co-morbidities. Importantly, all the data are standardized to the time of diagnosis.
17 These features, combined with a very large sample size, offer a unique opportunity to arrive
18 at a more comprehensive understanding of how Repetitive Motor Behaviours, Insistence on
19 Sameness, and Circumscribed Interests RRB domains are related to other individual
20 characteristics such as sex, CA, IQ, social-communicative impairments and the presence of
21 ADHD, at the time of diagnosis. Given mixed findings across the above reviewed studies and
22 specific nature of this sample (data collected at the time of the diagnosis), it was difficult to
23 form firm hypotheses. However, we expected positive relationship between Insistence on
24 Sameness with CA and FSIQ and the opposite pattern for Repetitive Motor Behaviors. It was
25 further expected that male gender would be associated with higher levels of RRB.

1 **Methods**

2 *Autism assessments and diagnoses in WA*

3 In WA, eligibility for ASD-specific services is dependent on a joint diagnosis by a
4 team of three clinicians (paediatrician, clinical psychologist and a speech pathologist)
5 (Glasson et al 2008). This has enabled a uniform and consistent approach to the diagnostic
6 decisions, service eligibility, reporting requirements and assessor training for ASD
7 assessments and services to children throughout WA over a number of decades. In cases
8 where children are younger than 12 years of age, the diagnostic assessments are performed by
9 a team of paediatrician or psychiatrist, psychologist, and speech-language pathologist. For
10 adolescents and adults, assessments are performed by a clinical psychologist, a paediatrician
11 (for adolescents) and/or a psychiatrist, as well as a speech-language pathologist as needed
12 (Glasson et al., 2008).

13 *Sample*

14 Data for this study were sourced from the WA ASD Register (established in 1999), an
15 independent, prospective collection of demographic and diagnostic information of individuals
16 newly diagnosed with ASD across WA in both government and private settings (Glasson et
17 al., 2019; Whitehouse et al., 2017). At the time of diagnosis, the diagnosing clinicians
18 voluntarily submit demographic and diagnostic information directly to the Register including
19 the severity of individual criteria used for the diagnosis, cognitive assessments, language
20 abilities, adaptive behaviour and the presence of comorbid conditions such as anxiety and
21 ADHD (for more detail please see Glasson, 2002). The collection of data for the Register
22 involved active recapture of any missed cases between 1999-2006 and hence this period of
23 data collection is considered complete. However, from 2007 recapture of missed cases was
24 not performed due to changes in governance associated with service provision, and so this
25 period will not be complete as it solely relied on voluntary notifications. It is not possible to

1 provide percentages or statistics to quantify the completeness as the Register itself is the only
2 comprehensive source of data collection in WA for diagnoses occurring during the childhood
3 period and hence no other comparative statistics exist from which to measure its
4 completeness.

5 Data collection has ethical approval from the Perth Children’s Hospital Human
6 Research Ethics Committee (294EP).

7 *Diagnostic and behavioural characteristics*

8 In addition to the information on age at diagnosis and sex, diagnosing clinicians were
9 asked to rate each of the DSM-IV-TR items on a 4 point Likert severity scale (0 “Criteria
10 Definitely NOT met”, 1 “Criterion questionable/partially met”, 2 “Clearly meets criterion (to
11 mild or moderate degree)” and 3 “Clearly meets criterion (to an extreme degree)”). For each
12 of the 12 DSM-IV assessment scales, in order for a criterion to be considered to be met (in
13 accordance with the DSM’s descriptions) a severity rating of at least 2 must be given. This
14 rating scale is not a part of the formal DSM diagnostic process but represents a clinically
15 based construct devised and adopted by Western Australian clinicians (Glasson et al., 2008).
16 All Western Australian ASD diagnosticians are encouraged to attend a cross-service meeting,
17 occurring at quarterly intervals, to discuss diagnostic issues, including standardisation of the
18 severity ratings. While attendance at these meetings was encouraged, it was not mandatory.
19 Descriptive statistics for social, communication, and RRB items are presented in Table 1.

20 In this paper, we focus on the presence and severity of the following RRB domains:
21 stereotyped and restricted patterns of interests (hereafter Circumscribed Interests), inflexible
22 and rigid adherence to specific routines (hereafter Insistence on Sameness) repetitive motor
23 mannerisms (hereafter Repetitive Motor Behaviours). This decision was guided by the fact
24 that these three behavioural types map onto the corresponding factors that have consistently
25 emerged across factor analytic studies that have explored the structure of RRB domain.

1 Overall scores were generated for the social and communication subscales by taking the
2 mean of the individual scores within that subscale. In addition, diagnosticians reported FSIQ
3 (Mean FSIQ= 85.65; SD=21.27) derived from standardized tests including the Bayley Scales
4 of Infant Development, Stanford Binet Intelligence Scale, Mullen Scales of Early Learning,
5 Wechsler Preschool and Primary Scale of Intelligence, or Wechsler Intelligence Scale for
6 Children.

7 Insert Table 1 Here

8 *Statistical Analysis*

9 The analyses were broadly descriptive and exploratory in an effort to characterize the
10 relationship between measures; descriptive statistics are presented as mean (standard
11 deviation) or N (percentage). The two primary variables of interest were the RRB rating
12 (Circumscribed Interests, Insistence on Sameness, and Repetitive Motor Behaviours) and
13 Full-Scale IQ (FSIQ) score, with an additional interest in how these two variables were
14 associated. FSIQ data were available for 42.6% of participants. Cohort characteristics are
15 presented for the full cohort, the subgroup with FSIQ data, and the subgroup without FSIQ.
16 Importantly, there were no significant differences between subgroups with and without FSIQ
17 information. The lack of FSIQ of data is largely due to variation in the assessment protocol
18 used across cases and centers.

19 Kendall's tau coefficient was used to assess the correlation between ordered
20 categorical variables and to characterise the concordance of the RRB ratings with both the
21 Autism Diagnostic Observation Schedule (ADOS; Lord et al., 2012) and the Autism
22 Diagnostic Interview-Revised (ADI-R; Rutter, Le Couteur, & Lord, 2003) RRB ratings.
23 Ordinal logistic regression was used to analyze each RRB rating (0,1,2,3) as an outcome,
24 with Odds Ratios (OR) and 95% Confidence Intervals (95% CI) reported. FSIQ was analyzed
25 both as a continuous outcome measure and as a dichotomous 'Low IQ' outcome measure

1 For each of the RRB, the most common rating was 2, observed for 38.9% of
2 participants for Insistence on Sameness and 50.4% of participants for both CI and Repetitive
3 Motor Behaviours; the least common rating was 3 (ranging 3.5% to 3.3%; Table 1). The
4 correlation between RRB ratings, as measured by Kendall's Tau, was weak, ranging in
5 magnitude from 0.00 for 'Circumscribed Interests and Repetitive Motor Behaviours (female)
6 to 0.20 for 'Insistence on Sameness and Repetitive Motor Behaviours (male) (Figure 1).
7 Repetitive Motor Behaviours and Insistence on Sameness, independently, were not associated
8 with Circumscribed Interests (Supplementary Table S1). A 1 unit increase in Repetitive
9 Motor Behaviours was significantly associated with a higher Insistence on Sameness rating
10 (OR 1.59; 95% CI 1.47,1.72), and, a 1 unit increase in Insistence on Sameness was
11 significantly associated with a higher Repetitive Motor Behaviours rating (OR 1.53; 95% CI
12 1.43,1.65). Effect size estimates for these associations did not significantly differ when each
13 of the two RRB were entered into the model, together, to predict the third. The correlation
14 between the clinician RRB ratings of interest and the ADI-R (N= 596; 16.34% of the total
15 sample) and ADOS (N= 211; 5.78% of the total sample; all individuals with ADOS also had
16 ADI-R data available) scores ranged 0.18 to 0.31 and 0.10 to 0.23 in magnitude, respectively.

17 Insert Figure 1 Here

18 *Relationship between RRB domains and age, sex, IQ and ADHD*

19 An older age at ASD diagnosis was significantly associated with a lower rating for
20 Circumscribed Interests (OR 0.96; 95% CI 0.94,0.97) but a higher rating for Insistence on
21 Sameness (OR 1.06; 95% CI 1.05,1.08) and Repetitive Motor Behaviours (OR 1.07; 95% CI
22 1.06,1.09), Supplementary Table S1. Comorbid ADHD was significantly associated with a
23 higher rating for Insistence on Sameness (OR 1.38; 95% CI 1.13,1.69) and Repetitive Motor
24 Behaviours (OR 1.27; 95% CI 1.03,1.58) but not Circumscribed Interests. In the full cohort
25 analysis, a significant association was observed between male sex and a higher rating for

1 Repetitive Motor Behaviours (OR 1.81; 95% CI 1.54,2.12), but not for Insistence on
2 Sameness (OR 1.01; 95% CI 0.86, 1.18) or Circumscribed Interests (OR 0.93; 95% CI 0.79
3 1.09). Distribution of Circumscribed Interests for females and males across different age
4 groups for the entire sample is shown in Table 2a. Tables 2b and 2c show distribution of
5 Circumscribed Interests ratings for females and males across different age groups separately
6 for individuals without intellectual disability and with intellectual disability respectively.

7 The linear nature of the relationship between each RRB and FSIQ, by sex, was
8 examined and validated graphically (Figure 2). An increase of one unit in Circumscribed
9 Interests rating, for males, was significantly associated with a lower FSIQ score
10 (unstandardized coefficient -3.74; 95% CI -5.11,-2.38) and an increased odds (OR 1.52; 95%
11 CI 1.31,1.77) of having a low IQ (Supplementary Table S2). Effect sizes were smaller and
12 not statistically significant for females, however, they were in the same direction. An increase
13 of one unit in Insistence on Sameness rating, for males, was significantly associated with a
14 higher FSIQ score (unstandardized coefficient 3.61; 95% CI 2.23,4.99) and a decreased odds
15 (OR 0.72; 95% CI 0.62,0.83) of having a low IQ (Supplementary Table S2); these effect sizes
16 were also significant and larger in magnitude within females, unstandardized coefficient 5.95
17 (95% CI 3.20,8.69) and OR 0.56 (95% CI 0.41,0.75) respectively. Observations for
18 Repetitive Motor Behaviours were similar to those of Insistence on Sameness, with the effect
19 sizes being attenuated. The relationship between each RRB and age was examined visually
20 using a LOESS non-parametric regression line. A clear change in the relationship occurred
21 around the age of eight 8 years, hence, a linear spline model was hit with a knot at 8 years
22 (Figure 3). This showed a significant increase in both Insistence on Sameness and Repetitive
23 Motor Behaviours (0.11 and 0.08 units per year of age, respectively) and a decrease in
24 Circumscribed Interests (-0.05 units per year of age) prior to age 8, which contrasted to a less
25 rapid change after 8 years (-0.001, 0.001, -0.012 units per year of age, for Insistence on

1 Sameness, Repetitive Motor Behaviours, and CI respectively; not significant with the
2 exception of CI).

3 Insert Figure 2 Here

4 Insert Figure 3 Here

5 Following a visual inspection of FSIQ scores by each RRB for sex and age (Figure 4),
6 regression models stratified by age were fitted. Circumscribed Interests and Repetitive Motor
7 Behaviours appeared to be best explained within a two-level cohort structure (0-12, 13+
8 years), whereas the relationship with Insistence on Sameness was less clear so was modeled
9 within a four-level cohort structure (Supplementary Table S3). The magnitude of the decrease
10 in IQ for males, for each unit increase in Circumscribed Interests, was significant in both
11 cohorts but larger in magnitude (-6.5 units; 95% CI -10.1,-2.9) among those diagnosed with
12 ASD after age 13 years than those diagnosed prior (-3.3 units; 95% CI -4.7,1.9); this
13 difference was not observed for females. For Repetitive Motor Behaviours in males, a one
14 unit increase in Repetitive Motor Behaviours was significantly associated with an increase
15 (3.3 units; 95% CI 1.8,4.8) in IQ among those diagnosed with ASD prior to age 13 years,
16 with a decline (not significant) observed for those diagnosed after age 13 years; this pattern
17 differed in females where an increase was observed for both groups, albeit not significant for
18 those diagnosed after age 13 years. The magnitude of the relationship between Insistence on
19 Sameness and FSIQ was smallest in magnitude and not significant within the cohort aged 7 to
20 12 years at the time of ASD diagnosis for both sexes; the increase in FSIQ for each unit
21 increase in Insistence on Sameness was largest in magnitude and significant among those
22 diagnosed between ages 4 and 6 years for females (8.6 units; 95% CI 4.4,12.8), and those
23 diagnosed between ages 0 and 3 years for males (5.3 units; 95% CI 2.5,8.1).

24 Insert Figure 4 Here

25 *Analysis of RRB and social and communication scales*

1 Behaviours, with small effect sizes and a lack of statistical significance observed for both
2 Insistence on Sameness and Circumscribed Interests. The lack of significant relationship
3 between sex and Circumscribed Interests is particularly interesting to consider given that this
4 RRB domain can be atypical in terms of content, focus and intensity and focusing on only
5 one of these aspects can result on either over- or under-estimation of sex differences. A study
6 by Sutherland et al. (2017) is particularly informative in this regard given that while they did
7 not find sex differences in terms of Circumscribed Interests frequency, which is consistent
8 with findings reported here, differences were present in terms of Circumscribed Interests
9 content. Therefore, future research with comprehensive assessment of Circumscribed
10 Interests domain are needed to further clarify and characterize this RRB domain.

11 Associations with CA, FSIQ and ADHD suggested somewhat distinctive patterns—while
12 Insistence on Sameness and Repetitive Motor Behaviours ratings were significantly related to
13 older age and higher FSIQ, the opposite was the case for Circumscribed Interests. Comorbid
14 ADHD was significantly associated with a higher rating for Insistence on Sameness and
15 Repetitive Motor Behaviours but was not significantly related to Circumscribed Interests. We
16 further conducted a series of exploratory analyses to provide a more detailed understanding
17 of the relationship between FSIQ and RRB domains across different age periods. For
18 Circumscribed Interests, the magnitude of the significant negative association between CA
19 and FSIQ was larger for the individuals aged 13 years and older than for the younger group.

20 The relationship between Insistence on Sameness and FSIQ across ages was more complex,
21 with both females and males showing the magnitude of the effect for the Insistence on
22 Sameness-FSIQ relationship being smallest and not significant in the 7 to 12 year-old cohort
23 for females and 13+ cohort for males, and largest in magnitude and significant in the 4-6
24 year-old females and the 0-3 year-old males.

1 The positive significant association identified in this study between Insistence on
2 Sameness with age and FSIQ aligns with the conceptualization of this RRB domain as higher
3 order domain and with findings from both longitudinal and cross-sectional studies (Bishop et
4 al., 2006; Richler et al., 2010). Based on the fact that during normative development,
5 occurrence and rise in Insistence on Sameness tend to be concomitant with the occurrence of
6 normative fears (Evans et al., 1999) it has been suggested that Insistence on Sameness serves
7 as an early form of self-regulation by exerting control, constraining the environment thus
8 limiting unpredictability, and reducing normative fears (Uljarević et al., 2017a; Uljarević &
9 Evans, 2017; Uljarević et al., 2019). Normative fears occur at earlier stages of typical
10 development, and, unlike clinical anxiety, are transitory in nature (Gullone, 2000). Therefore,
11 it is not surprising that in our study, the magnitude of the effect between FSIQ and Insistence
12 on Sameness changed across different age groups. Contrary to our findings, Richler et al.
13 (2010) reported no evidence of an IQ-Insistence on Sameness association at age 2 nor the
14 influence of IQ on subsequent change in Insistence on Sameness scores over time, however,
15 this study focused on only effects of non-verbal IQ (NVIQ) and therefore did not tap into
16 more symbolic levels of development.

17 Although empirical findings thus far have been largely inconsistent, with studies
18 showing both negative (Bishop et al., 2006; Esbensen et al., 2009) and non-significant
19 associations (Hus et al., 2007; South et al., 2005) of Repetitive Motor Behaviours with CA
20 and FSIQ; no studies to date have reported significant positive association. Compared to
21 Insistence on Sameness and Repetitive Motor Behaviours, the Circumscribed Interests
22 domain has been under-researched, with studies reporting both a positive (Bishop et al.,
23 2013) and the lack (Lam et al., 2008; South et al., 2005) relationship of Circumscribed
24 Interests with CA and IQ. To our knowledge, no studies have reported a significant negative
25 relationship. However, it is important to have in mind the nature of the WA ASD Register

1 dataset. More specifically, this study is rare in the sense that it records age at diagnosis and
2 data is standardised to the time of diagnosis. Therefore, some of the inconsistencies, when
3 compared to previous studies, could be related to presenting factors at the age of diagnosis.
4 For example, children tend to be diagnosed earlier due to language delay and social-
5 communication difficulties, rather than specific concerns with regard to RRB, and these
6 issues might override other signs. Therefore, it is possible that, for the children who are
7 diagnosed earlier in life, the relationship between RRB and FSIQ noted at the time of
8 diagnosis will change when they are older. For instance, it is possible that children who are
9 referred to diagnostic evaluation at younger age might exhibit Circumscribed Interests that
10 are either more unusual in terms of their content or more intense (or both) and that children
11 who are referred later (and have higher FSIQ) exhibit Circumscribed Interests that are either
12 less unusual in their content or their intensity or have learned to camouflage them in
13 particular contexts.

14 Our findings suggest that the severity of communication deficits provided stronger
15 prediction for Circumscribed Interests as opposed to Insistence on Sameness and Repetitive
16 Motor Behaviours. The severity of social impairments was a significant predictor of all three
17 RRB domains. While several studies have indicated a positive relationship between the
18 degree of social and communication impairments, and frequency and severity of both
19 Repetitive Motor Behaviours (Hus et al., 2007; Lam et al., 2008; Szatmari et al., 2006) and
20 Insistence on Sameness (Cannon et al., 2010; Lam et al., 2008), other studies have found
21 either no association (Harrop et al., 2014) or even a negative relationship (Richler et al.,
22 2010). The Circumscribed Interests factor was not related to other core ASD traits in a study
23 by Lam and colleagues (2008).

24 When considering what mechanisms account for the association of RRB domains
25 with social and communication impairments, it is important to take into account

1 developmental trajectory and the functions of RRB domains during normative development.
2 Normative Repetitive Motor Behaviours and Insistence on Sameness are suggested to play
3 adaptive roles during development with Repetitive Motor Behaviours being associated with
4 neuromuscular development (Thelen, 1979; Uljarević et al., 2017c) and Insistence on
5 Sameness, as already noted, acting as a means of limiting unpredictability and reducing
6 ensuing fears (Laing et al., 2009; Leekam et al., 2011; Uljarević et al., 2017a; Uljarević et al.,
7 2019). Although Repetitive Motor Behaviours and Insistence on Sameness are adaptive
8 during early development, if they persist, they may negatively influence subsequent
9 development (Larkin et al., 2017; Leekam et al., 2011). For instance, Insistence on Sameness
10 serve to regulate and reduce stress via constraining the unpredictability of environment,
11 however, if elevated and persistent, they may also reduce exposure to situations conducive to
12 learning and socio-emotional development (Leekam et al., 2011; Uljarević et al., 2017a).
13 Similarly, intensity and inability to inhibit Circumscribed Interests can limit child's
14 involvement in other activities, and interfere with learning and the formation of social
15 relationships. This is supported by our findings that both Insistence on Sameness and
16 Circumscribed Interests were related to greater social problems and that Circumscribed
17 Interests was related to greater communication problems. When considering the dynamics of
18 the relationships between RRB and social and communication impairments, two additional
19 scenarios are also possible. Firstly, children with more severe levels of social and
20 communicative impairments have a lower likelihood of being exposed to novel situations that
21 are conducive to the development of flexible patterns of behaviours and interests. Secondly, it
22 may also be the case that lower social motivation and lower social engagement lead
23 individuals to be more focused on internal stimuli and stimulation, be more rigid and insistent
24 on sameness, and prefer Circumscribed Interests to other forms of engagement, or it might be

1 a combination of both processes. Future longitudinal research is needed to address questions
2 raised above as they have direct implications for the conceptualization of ASD as a disorder.

3 Our study focused on using a large, well-characterized sample of individuals with
4 ASD to explore evidence for Repetitive Motor Behaviours, Insistence on Sameness and
5 Circumscribed Interests as distinct RRB domains. However, despite the strengths of the
6 sample, it is important to acknowledge the limitations and limited range of the RRB
7 assessment utilized in this study. While attempts have been made to standardise severity
8 ratings amongst diagnosticians within Western Australia (through quarterly standardisation
9 meetings), it is possible that inter-rater variability influenced the findings. RRB clinician
10 ratings utilized in this project were associated with RRB scores from ADOS and ADI-R.
11 However, the strength of associations was small to moderate which can be explained by the
12 lack of variability in both clinician ratings and ADOS RRB score, as well as by the fact that
13 both ADOS and ADI-R provided total, rather than more fine-grained subscale scores.
14 Further, numbers of participants with ADI-R and ADOS data was small. The range for each
15 of the items and the conclusions are further limited by the very nature of the sample. More
16 specifically, the cohort examined here consisted of individuals diagnosed with ASD,
17 therefore, majority of them would have exhibited symptoms within at least one of the RRB
18 domain, and therefore further restricting the *variability* in RRB scores. Despite this
19 limitation, varied relationships both with RRB measures and with RRB measures and other
20 outcomes were observed; nevertheless, this limitation needs to be considered when
21 interpreting the pattern of findings reported here. Due to the design of the data collection
22 from clinicians, long data collection period (1999-2014) and large number of clinicians
23 involved, it was not possible to formally explore the presence of systematic differences in
24 clinicians' ratings, a limitation that is important to consider. ASD diagnosticians are
25 encouraged to attend quarterly meetings to discuss diagnostic issues and recommendations

1 for diagnostic practices, including standardisation of the severity ratings, however, the rates of
2 diagnosticians that attend these meetings is not available. It is important however to
3 emphasize that while attendance at meetings is variable, the diagnostic process and pathways
4 to services in WA is modelled on the formal recommendations of the group on behalf of all
5 ASD diagnosticians and must be adhered to by those conducting diagnostic assessments.
6 Finally, this study was restricted to the ratings of the DSM-IV-TR criteria. Repetitive Motor
7 Behaviours, Insistence on Sameness and Circumscribed Interests RRB subdomains have
8 remained unchanged across DSM-IV-TR and DSM-5 diagnostic systems, however, DSM-5
9 criteria explicitly requires the presence of RRB for the ASD diagnosis which was not the case
10 in DSM-IV-TR. Given that the data reported here were collected at the time of diagnosis, it
11 will be important to further explore whether the inter-relationship between RRB subdomains
12 with social and communication aspects of ASD phenotype might to some extent differ for
13 individuals diagnosed across these two incarnations of the international diagnostic systems.

14 Regardless of the measurement limitations, findings reported here provide further
15 support to the proposal about the potential utility of RRB domains for stratifying the larger
16 ASD population into smaller, more phenotypically homogenous subgroups that can help to
17 facilitate efforts to understand diverse ASD etiology and inform the design of future
18 interventions. Development of targeted and effective interventions of RRB is a particular
19 priority given that certain RRB can have negative impact on certain aspects of functioning
20 and the current lack of dedicated treatment options (Harrop, 2015; Grahame et al., 2015).
21 However, it is also important to point out that not all RRB require treatment. Indeed recent
22 papers utilizing focus group format suggest that individuals with ASD perceive that certain
23 RRB can serve a range of important functions including reducing external stimuli and coping
24 with stress (Joyce, Honey, Leekam, Barrett, & Rodgers, 2017; .Kapp et al., 2019; Manor-
25 Binyamini & Schreiber-Divon, 2019). The pattern of associations identified in this study

1 provides tentative evidence for the distinctiveness of Repetitive Motor Behaviours, Insistence
2 on Sameness, and Circumscribed Interests and lends support to the notion that interventions
3 should target specific RRB. This is further supported by the relatively recent small scale,
4 pilot Randomised Controlled Trial of a parent group intervention by Grahame and colleagues
5 (2015) which reported that for instance targeting Circumscribed Interests had a positive
6 impact on that particular RRB domain but not on Repetitive Motor Behaviours. Further, as
7 noted, existing evidence suggests that elevated anxiety and impaired cognitive control are
8 related to IS but not Repetitive Motor Behaviours (Lidstone, Uljarević et al., 2014; Uljarević
9 et al., 2017a; Uljarević et al., 2019) indicating that targeting anxiety and impaired self-
10 regulation might be a viable mechanisms for reducing Insistence on Sameness but not
11 Repetitive Motor Behaviours. Since RRB represent dimensional traits that intersect a wide
12 range of neurodevelopmental and neuropsychiatric disorders and extend well into the general
13 population (Evans et al., 2017; Leekam et al., 2011; Uljarević et al., 2017b; Uljarević et al.,
14 2019) it will be important for future studies to explore evidence for the distinctiveness of
15 RRB domains across both typical development and disorders using sensitive and
16 comprehensive RRB measures such as the Repetitive Behaviour Questionnaire-2 (RBQ-2;
17 Barrett et al., 2015) and the Childhood Routines Inventory-Revised (Evans et al., 2017).

Key Points:

- Restricted and repetitive pattern of behaviours (RRB) are a cardinal feature of autism spectrum disorder (ASD), but there remains uncertainty about how these diverse behaviours vary according to individual characteristics.
- This study utilized an internationally unique prospective state-wide cohort to provide the most comprehensive exploration to date of whether Repetitive Motor Behaviours, Insistence on Sameness and Circumscribed Interests RRB domains can be distinguished based on their patterns of associations with other individual characteristics.
- When considering the pattern of associations of RRB with other subject characteristics identified in this study, there was suggestive evidence that Repetitive Motor Behaviours, Insistence on Sameness, and Circumscribed Interests were differently related to sex, CA, FSIQ, social and communication deficits and ADHD.
- The pattern of associations identified in this study provides suggestive evidence for the distinctiveness of Repetitive Motor Behaviours, Insistence on Sameness, and Circumscribed Interests, suggesting the potential utility of RRB domains for stratifying the larger ASD population into smaller, more phenotypically homogeneous subgroups that can help to facilitate efforts to understand diverse ASD etiology and inform design of future interventions.

Figure 1: Heat map of RRB rating concordance, for each RRB pair by sex.

Note: Concordance between RRB ratings is characterized by Kendall's tau coefficient; CI: Circumscribed Interests; IS: Insistence on Sameness; RMB: Repetitive Motor Behaviours; RRB: Restricted and Repetitive behaviours.

Figure 2: Violin plot showing the distribution of Full Scale IQ for each RRB by sex

Note: CI: Circumscribed Interests; IS: Insistence on Sameness; RMB: Repetitive Motor Behaviours; RRB: Restricted and Repetitive behaviours.

Figure 3: Plot showing regression line (from a two-stage spline fit) for RRB score against age at Autism diagnosis

Note: CI: Circumscribed Interests; IS: Insistence on Sameness; RMB: Repetitive Motor Behaviours; RRB: Restricted and Repetitive behaviours. Lines are generated from a two-stage linear spline model, with a split at age 8 years; grey bands represent 95% confidence interval; truncated beyond age 30 years to due to sparse data.

Figure 4: Plot showing the distribution of Full Scale IQ against each RRB by sex and age of diagnosis category

Note: CI: Circumscribed Interests; IS: Insistence on Sameness; RMB: Repetitive Motor Behaviours; RRB: Restricted and Repetitive behaviours.
