4 **Abstract**  
5

6 Pseudocapacitors have recently attracted attention from the scientific community as a  
7 promising new energy storage system, which can potentially bridge the performance gap  
8 between lithium ion batteries and conventional capacitors. To further improve the  
9 performance of these pseudocapacitors, tailoring the binary metal oxide along with  
10 developing new methods for controlling resultant nanostructures in a predictive way is an  
11 essential requirement for achieving more favorable electrochemical kinetics. Here, through a  
12 simple hydrothermal synthetic procedure that uses different supersaturation states to alter the  
13 driving force for crystal growth, we have managed to obtain one-dimensional (1-D) Nickel  
14 Molybdenum Oxide (NiMoO<sub>4</sub>) electrodes on a nickel foam. The morphology of the 1-D  
15 NiMoO<sub>4</sub> nanostructures can be tuned from a low to a high aspect ratio (over a range of  
16 diameter sizes from 80 to 800 nm). Such a controllable structure provides a platform for  
17 understanding the electrochemical relationships in terms of fast retention times and improved  
18 ion diffusion coefficients, enabling the demonstration of promising electrochemical storage  
19 properties. We show that the 1-D NiMoO<sub>4</sub> electrode with a high aspect ratio (HAR) exhibits a  
20 much higher specific capacitance of 1335 F g<sup>-1</sup> at a current density of 1 A g<sup>-1</sup>, which is due to  
21 the unique physical and chemical structure being suitable for electrochemical kinetics. We  
22 further demonstrate that an asymmetric supercapacitor consisting of the tailored HAR-  
23 NiMoO<sub>4</sub> electrode can achieve an energy density of 40.7 Wh kg<sup>-1</sup> and a power density of 16  
24 kW kg<sup>-1</sup>.

## 1. INTRODUCTION

Electrochemical supercapacitors are currently being considered as promising candidates for next-generation energy storage applications since they have the potential to bridge the gap between batteries and conventional capacitors for the production of high power and high energy densities. Furthermore, they have been shown to exhibit a good rate capability, long cycling life time, and environmentally friendly characteristics.<sup>1-3</sup> In particular, pseudocapacitors, which possess the capability to store large amounts of charge *via* fast and reversible electrochemical Faradaic redox reactions, have enormous potential in a broad variety of applications, including electric vehicles and portable electronic devices.<sup>4,5</sup> Currently, transition metal oxides/hydroxides such as RuO<sub>2</sub>, Ni(OH)<sub>2</sub>, Co<sub>3</sub>O<sub>4</sub> and MnO<sub>2</sub>, are most commonly used as the electrode materials with high theoretical capacitances because of their multiple oxidation states, enabling rich electrochemical Faradaic reactions.<sup>6-9</sup>

Despite their compelling benefits combined with the inherently high electrochemical activities, their low conductivity and structural instability, which leads to a reduction in the performance, continuously hinders the successful exploitation of pseudocapacitor technology in practical applications.<sup>10</sup> To overcome these limitations, numerous studies have been devoted to enhancing the electrochemical properties of the pseudocapacitors by focusing on the development of new electrode materials that are based on binary transition metal oxides.<sup>11-14</sup> These materials typically exhibit a higher electrical conductivity and richer chemical valence states than the single-component transition metal oxides, which arises from the combined contributions from both metal atoms.<sup>11-14</sup> Among the various binary metal oxides, transition metal molybdates such as NiMoO<sub>4</sub> and CoMoO<sub>4</sub> are an emerging class of pseudocapacitor materials that have received considerable attention due to their cost-effectiveness, abundance, and chemical stability.<sup>15,16</sup> More specifically, the primary interest in NiMoO<sub>4</sub> lies in the fact that the high specific capacitance from the Ni atom and the high

1  
2  
3  
4 electrical conductivity from the Mo atom can contribute collectively to the superior  
5  
6 electrochemical behavior when used in energy storage devices.<sup>17</sup> Combined, these features  
7  
8 demonstrate that NiMoO<sub>4</sub> has potential in future pseudocapacitor energy storage systems.  
9

10  
11 Alternatively, various nanostructuring approaches have been developed to address  
12  
13 issues related to limited electrochemical kinetics on the surface, which are strongly associated  
14  
15 with a low degree of surface contact areas and low ion diffusion rates.<sup>18-19</sup> These more recent  
16  
17 strategies have shown that hierarchical nanostructures with diverse morphologies and  
18  
19 dimensions (D) can provide more active sites and shorter ion diffusion pathways, which then  
20  
21 stimulate and facilitate the kinetics associated with the electrochemical reactions. In  
22  
23 particular, 1-D nanostructures are one of the most widely used architectures for  
24  
25 electrochemical storage devices mainly because 1) the unique geometry results in a large  
26  
27 contact surface area; 2) the structures exhibit short diffusion distance; 3) they exhibit good  
28  
29 structural stability and 4) they possess a favorable charge carrier path during the  
30  
31 charge/discharge processes. Nevertheless, synthesizing these 1-D structures in binary metal  
32  
33 oxides in a controlled way still remains a challenge and is mainly due to the complex  
34  
35 stoichiometry-dependent synthetic reactions. Further, even though there have been few  
36  
37 reports<sup>20-21</sup> that have studied the dependence of the electrochemical storage performance on  
38  
39 the different nanostructures, there are no detailed studies that directly describe the  
40  
41 electrochemical ion intercalation mechanism for engineering 1-D nanostructures with tailored  
42  
43 aspect ratios.  
44  
45  
46

47  
48 It is, therefore, highly desirable that a novel and facile synthetic route for the  
49  
50 preparation of 1-D nanostructured binary metal oxides with different aspect ratios be  
51  
52 developed that can enhance the charge transfer kinetics so as to improve charge  
53  
54 transportation. Moreover, developing such a procedure would enable us to understand how  
55  
56 the charge storage dynamics and electrochemical stability depends upon the nanostructure  
57  
58  
59  
60

1  
2  
3  
4 and how this can lead to a superior pseudocapacitor performance. To this end, we have  
5  
6 employed the fundamental principle of hydrothermal reaction kinetics whereby the nucleation  
7  
8 and crystallization growth rates can depend crucially on the supersaturation states of the  
9  
10 solvents, which are the major driving forces for solution-based synthetic processes as shown  
11  
12 in Figures 1a-c.<sup>22</sup> Controlling the rational supersaturated environments enables the synthesis  
13  
14 of 1-D NiMoO<sub>4</sub> nanostructures with different, but predictable, morphologies. In this regard,  
15  
16 we propose a simple and facile way for the rational and precise design of the desirable  
17  
18 supersaturation levels, which in turn affects the crystal nucleation rates and preferred crystal  
19  
20 growth geometries and directions thereby leading to different 1-D aspect ratios. Moreover,  
21  
22 the different 1-D NiMoO<sub>4</sub> nanostructures can result in a diverse range of electrochemical  
23  
24 behavior including specific capacitance as well as ion diffusion and charge transfer dynamics.  
25  
26 Through the control of these properties, it therefore provides one of the best routes for the  
27  
28 design of new electrode materials for high-performance supercapacitors.

## 35 **2. EXPERIMENTAL DETAILS**

### 36 **2.1 Material synthesis: NiMoO<sub>4</sub> nanostructures on a Ni foam.**

37  
38  
39  
40 Different 1-D NiMoO<sub>4</sub> nanostructures with different aspect ratios on nickel foams  
41  
42 were synthesized by a hydrothermal method. First, a conductive Ni foam (1 cm x 1 cm) was  
43  
44 cleaned using 1 M HCl, ethanol, and deionized water. In a typical synthesis, 1.0 mmol of  
45  
46 Ni(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O and 1.0 mmol of Na<sub>2</sub>MoO<sub>4</sub> were dissolved in deionized water at room  
47  
48 temperature to form a clear green solution. After being stirred for an hour, the solution was  
49  
50 transferred into a 45 ml Teflon-lined cup, and then the Ni foam was transferred into the  
51  
52 Teflon-lined cup and a stainless steel autoclave. The hydrothermal reaction was carried out at  
53  
54 140 °C for 4 hr. After cooling down naturally to room temperature, the Ni foam was collected  
55  
56 and washed several times with water and ethanol to remove loosely attached NiMoO<sub>4</sub> on the  
57  
58  
59  
60

1  
2  
3  
4 Ni foam. The foam was then fully dried at 60 °C for 12 hr. In order to obtain the crystallized  
5  
6 NiMoO<sub>4</sub> nanostructures, the Ni foam with the NiMoO<sub>4</sub> nanostructure was calcined at 400 °C  
7  
8 for 2 hr in an argon atmosphere. The different nanostructures of the NiMoO<sub>4</sub> material were  
9  
10 synthesized using various solvents with different mixtures of solvents such as water, ethanol  
11  
12 and hydrochloric acids.  
13

## 14 **2.2 Material characterization**

15  
16 Morphologies of the samples were characterized by SEM (Hitachi S-4300) and TEM  
17  
18 (JEOL JEM-2200MCO FEGTEM). The crystal structure of the samples was examined by  
19  
20 high resolution XRD (Rigaku Medel Smartlab) in a two theta range of 10-80°. The specific  
21  
22 BET surface area was calculated on the basis of nitrogen adsorption isotherms using  
23  
24 Micromeritics Gemini VI. XPS were recorded using a Thermo Scientific K-Alpha XPS  
25  
26 instrument equipped with a micro-focused mono-chromated Al X-ray source. The XPS  
27  
28 source was operated at 12 keV and a 400 μm spot size was used. The spectrometer was  
29  
30 adjusted to align a binding energy of 284.5eV for the C 1s line.  
31  
32  
33

## 34 **2.3 Electrochemical characterization**

35  
36 The electrochemical properties of the NiMoO<sub>4</sub> samples with different aspect ratios  
37  
38 were measured in a three-electrode system consisting of HAR-, MAR-, and LAR-NiMoO<sub>4</sub>  
39  
40 electrodes as working electrodes, Pt mesh as a counter electrode, and an Ag/AgCl electrode  
41  
42 (in saturated 3 M KCl) as a reference electrode. These were used to analyze CV, galvanostatic  
43  
44 charge/discharge, and EIS curves using a potentiostat (PGSTAT302N, Metrohm, Autolab).  
45  
46 For the fabrication of the anode electrodes, active carbon was prepared as an active material,  
47  
48 with poly(vinylidene difluoride) as a binder and Ketjen black as a conductive material, and  
49  
50 this was then coated onto the compressed nickel foam as a current collector. All  
51  
52 electrochemical results of the AC//HAR-NiMoO<sub>4</sub> ASC were measured using a two electrode  
53  
54 system under 1.0 M KOH solution at room temperature.  
55  
56  
57  
58  
59  
60

### 3. RESULTS AND DISCUSSION

The morphology and structural characteristics of the as-prepared NiMoO<sub>4</sub> materials were investigated by scanning electron microscopy (SEM). As shown in Figures 1d-f, the controlled growth of the 1-D NiMoO<sub>4</sub> nanostructures with different aspect ratios was successfully achieved on a nickel foam through a hydrothermal process by adjusting the solubility level in the reaction solution and hence introducing various different supersaturation states during the growth phase. Obviously, as the relative solubility decreases, the morphology of the 1-D nanostructures is transformed through a series of distinct aspect ratios between length to breadth from a low (LAR) to a high value (HAR) through a medium value (MAR). Figure 1d shows an SEM image of the MAR-NiMoO<sub>4</sub> sample obtained from the DI water-only solution, which results in 1-D nanostructures with a diameter size of ~250 nm. In contrast, the HAR-NiMoO<sub>4</sub> sample with a diameter of about 80 nm is grown under low solubility conditions induced by adding an alkaline solvent into the water solution (Figure 1d). Finally, the LAR-NiMoO<sub>4</sub> sample has a diameter of 800 nm and was constructed by introducing an additional acidic solvent (Figure 1f). These findings indicate that introducing a low (high) solubility environment to the hydrothermal precursor solution induces the relatively high (low) degree of supersaturation, leading to a higher (lower) driving force for crystal nucleation and growth process. Therefore, the selective synthesis mechanism responsible for the different 1-D NiMoO<sub>4</sub> structures can be understood in terms of the control of the solvent solubility that leads to different degrees of supersaturation. Moreover, a predictable 1-D nanostructure synthetic route so as to grow the active materials directly on to a metal collector means that the driving force for nucleation and crystal growth can be controlled by changing the supersaturation states.

Next, the nanostructures of the HAR-, MAR- and LAR-NiMoO<sub>4</sub> samples were

1  
2  
3  
4 further characterized by transmission electron microscopy (TEM) to provide more insight  
5  
6 regarding their unique 1-D structure, as shown in inset images of Figures 1d-f. The TEM  
7  
8 images clearly demonstrate that the diameter of 1-D nanostructures for the as-prepared  
9  
10 NiMoO<sub>4</sub> samples is in good agreement with the SEM results. As a result of tuning the  
11  
12 solubility of the solvents, three different types of 1-D NiMoO<sub>4</sub> material with mean aspect  
13  
14 ratios of 21.6 (HAR-NiMoO<sub>4</sub>), 12.8 (MAR-NiMoO<sub>4</sub>), and 4.7 (LAR-NiMoO<sub>4</sub>) were  
15  
16 successfully prepared for use in a supercapacitor application (Supporting Information Figure  
17  
18  
19 S1).

20  
21  
22 To evaluate the crystallographic phase of the NiMoO<sub>4</sub> electrode samples, X-ray  
23  
24 diffraction (XRD) spectra were analyzed, which are shown in Figure 2a. All the diffraction  
25  
26 patterns obtained from the 1-D NiMoO<sub>4</sub> nanostructures with different aspect ratios are  
27  
28 unambiguously assigned to the NiMoO<sub>4</sub> phase (JCPDS Card No. 86-0361) without any  
29  
30 noticeable differences.<sup>23</sup> Moreover, to confirm the surface electronic states and chemical  
31  
32 compositions of the NiMoO<sub>4</sub> samples, X-ray photoelectron spectroscopy (XPS)  
33  
34 measurements were carried out. Figures 2c-d compare the high resolution XPS spectra of the  
35  
36 Ni 2p and Mo 3d of the 1-D NiMoO<sub>4</sub> samples with different aspect ratios, respectively. The  
37  
38 Ni 2p doublet is clearly observed at 854.9 eV (Ni<sup>2+</sup> 2p<sub>3/2</sub>) and at 872.5 eV (Ni<sup>2+</sup> 2p<sub>1/2</sub>) with a p  
39  
40 spin-orbit splitting of 17.6 eV.<sup>24</sup> Moreover, the two peaks at binding energies of 232.0 eV and  
41  
42 235.1 eV with the d spin-orbit splitting of 3.1 eV correspond to Mo<sup>6+</sup> 3d<sub>5/2</sub> and Mo<sup>6+</sup> 3d<sub>3/2</sub>,  
43  
44 respectively.<sup>25</sup> These XPS results suggest that there are only chemical oxidation states and  
45  
46 compositions of the Ni<sup>2+</sup> and Mo<sup>6+</sup> in the as-prepared 1-D NiMoO<sub>4</sub> whereby the Ni cations,  
47  
48 distributed in octahedral sites, are electrochemically active with OH<sup>-</sup> electrolyte ions and the  
49  
50 Mo cations in tetrahedral sites contribute to the electrochemical stability.

51  
52  
53 To further examine the specific surface area characteristics of the 1-D NiMoO<sub>4</sub>  
54  
55 structures, measurements of the N<sub>2</sub> adsorption-desorption were carried out (Supporting  
56  
57  
58  
59  
60

1  
2  
3  
4 Information Figure S2). As shown in Figure 2b, the calculated Brunauer-Emmett-Teller  
5 (BET) surface area of the HAR-NiMoO<sub>4</sub> sample has the largest value (97.26 m<sup>2</sup> g<sup>-1</sup>) and is  
6 much larger than the areas for the MAR-NiMoO<sub>4</sub> (50.32 m<sup>2</sup> g<sup>-1</sup>) and LAR-NiMoO<sub>4</sub> (25.66 m<sup>2</sup>  
7 g<sup>-1</sup>) samples, which is mainly due to the different aspect ratios of the nanostructures. This  
8 implies that the high surface area of the HAR-NiMoO<sub>4</sub> electrodes provides a sufficient  
9 electrolyte contact interface and can thus enhance the kinetics of ion diffusion. Consequently,  
10 a high aspect ratio can improve the electrochemical capacitance and the charge transfer  
11 kinetics.  
12  
13  
14  
15  
16  
17  
18  
19  
20  
21

22 In order to evaluate the electrochemical performance of the different 1-D  
23 morphologies, the HAR-, MAR- and LAR-NiMoO<sub>4</sub> were applied directly as working  
24 electrodes in a three electrode system. Supporting Information Figure S3 shows the cyclic  
25 voltammetry (CV) and the galvanostatic charge-discharge curves of the each NiMoO<sub>4</sub>  
26 electrode. First, the CV curves of all the NiMoO<sub>4</sub> electrodes have similar shapes with  
27 increasing scan rates, indicating that all the electrodes have good pseudocapacitive  
28 behavior.<sup>26</sup> For a direct CV performance comparison between the electrodes, Figure 3a  
29 presents the CV curves of the three different types of NiMoO<sub>4</sub> electrodes with the potential  
30 window ranging from 0.0 to 0.6 V at a scan rate of 5 mV s<sup>-1</sup>. It can be clearly observed that  
31 all the NiMoO<sub>4</sub> electrodes have a couple of Faradaic reaction peaks that can be ascribed to  
32 the reversible redox reaction between Ni(II) and Ni(III).<sup>27</sup> The area surrounded within the CV  
33 curve of the HAR-NiMoO<sub>4</sub> sample occupies the largest area, indicating the highest value for  
34 the electrochemical capacitance. This large CV area might be attributed to the larger  
35 electrolyte contact area for the HAR-NiMoO<sub>4</sub> electrode. Consistent with the CV results, the  
36 galvanostatic charge-discharge curves demonstrate that the HAR-NiMoO<sub>4</sub> electrode has the  
37 longest discharge time (Supporting Information Figure S3). Moreover, the calculated specific  
38 capacitance of the HAR-, MAR-, and LAR-NiMoO<sub>4</sub> samples at a current density of 1 A g<sup>-1</sup>  
39

5

6  
7 In order to better understand the ion diffusion behavior and charge transfer dynamics  
8 of the NiMoO<sub>4</sub> electrodes with tailored aspect ratios, kinetic electrochemical analysis was  
9 carried out. The inset of Figure 3a indicates the potential difference of each electrode between  
10 the anodic and cathodic peak, representing the degree of reversible intercalation and de-  
11 intercalation dynamics during the CV charge-discharge.<sup>28</sup> It can be seen that the HAR-  
12 NiMoO<sub>4</sub> electrode provides a much more appreciable OH<sup>-</sup> ion access and faster charge  
13 transfer rate. Moreover, the cathodic peak current densities of the NiMoO<sub>4</sub> electrodes were  
14 plotted as a function of the square root of the scan rates in Figure 3b. The cathodic peak  
15 currents increase linearly, showing that redox reactions at the surface are followed by a  
16 diffusion-controlled process with the OH<sup>-</sup> ions.<sup>29</sup> Also, it is evident that the cathodic peak  
17 current of the HAR-NiMoO<sub>4</sub> sample shows a steeper dependence compared to the other  
18 electrodes, indicating a larger diffusion coefficient. For a direct comparison of the ion  
19 diffusivity, the diffusion coefficients of the NiMoO<sub>4</sub> electrodes were calculated according to  
20 the following Randles–Sevcik equation.<sup>30</sup>  
21  
22  
23  
24  
25  
26  
27

$$i_p = (2.69 * 10^5) * n^{\frac{3}{2}} * A * D_0^{\frac{1}{2}} * C_0 * v^{\frac{1}{2}}$$

37  
38  
39  
40  
41 where  $i_p$  is the cathodic peak current density,  $n$  is the number of electrons,  $A$  is the electrode  
42 area,  $D_0$  is the diffusion coefficient,  $C_0$  is the electrolyte concentration, and  $v$  is the scan rate.  
43 We can assume that  $n$ ,  $A$ ,  $C_0$  have the same values in the same three electrode system.  
44 Therefore, the diffusion coefficient of the 1-D NiMoO<sub>4</sub> samples can be directly compared  
45 from the slope of the curve ( $D_0^{\frac{1}{2}} \propto i_p/v^{\frac{1}{2}}$ ). The diffusion coefficient of the HAR-NiMoO<sub>4</sub> sample  
46 is found to be 1.82 and 17.9 times larger than that of the MAR- and LAR-NiMoO<sub>4</sub> samples,  
47 respectively.  
48

58 Figure 3c presents the specific rate retention data as a function of the current density

59  
60  
1  
2  
3  
4 in the electrodes. From a low current density of 1 A g<sup>-1</sup> to a high current density of 20 A g<sup>-1</sup>,  
5  
6 the capacitance of the HAR-NiMoO<sub>4</sub> electrode shows good rate retention behavior, which is  
7  
8 found to be 882.4 F g<sup>-1</sup> at 20 A g<sup>-1</sup> with ~ 66.1 % retention compared to that for 1 A g<sup>-1</sup>. On the  
9  
10 other hand, for the MAR and LAR-NiMoO<sub>4</sub> electrodes the capacitance is recorded to be  
11  
12 668.8 F g<sup>-1</sup> and 146.0 F g<sup>-1</sup> with 60.5 % and 21.8 % rate retention, respectively. In other  
13  
14 words, the presence of the fast diffusion rate from the surface to the internal structure means  
15  
16 that the HAR-NiMoO<sub>4</sub> electrode exhibits much better retention performance.  
17

18  
19  
20 Finally, to elucidate further the ion diffusion and charge transfer behavior,  
21  
22 electrochemical impedance spectroscopy (EIS) measurements with Bode phase plots and  
23  
24 Nyquist plots were conducted and plotted, respectively (Figure 3d and Supporting  
25  
26 Information Figures S5). All the Nyquist plots for the NiMoO<sub>4</sub> electrodes show that the  
27  
28 charge transfer resistances ( $R_{ct}$ ), recorded from the diameters of the semicircle, are very low.  
29  
30 This outcome demonstrates that the NiMoO<sub>4</sub> electrodes grown directly on the Ni foam  
31  
32 current collector have nearly equal electrolyte resistance and superior charge transfer, which  
33  
34 minimizes interfacial resistance and facilitates charge transfer at the interface between the  
35  
36 current collector and electrode material. Furthermore, the linear part in the plot of the HAR-  
37  
38 NiMoO<sub>4</sub> sample in the low frequency region (Warburg impedance) is significantly steeper  
39  
40 than that for the MAR- and LAR-NiMoO<sub>4</sub> samples, suggesting that the HAR-NiMoO<sub>4</sub> has the  
41  
42 fastest ion diffusion and electrolyte access to the surface, which is consistent with the results  
43  
44 of the capacitance rate retention in Figure 3c.<sup>31</sup>  
45  
46

47  
48 Figure 3d shows the Bode phase plots for the NiMoO<sub>4</sub> electrodes with the different  
49  
50 relaxation time constant ( $\tau_0$ ). A relaxation time constant can be calculated from the x-axis  
51  
52 frequency when the curve reaches -45° on the Bode plot. The relaxation time constant is an  
53  
54 important parameter so as to compare between capacitive and resistive behaviors of a  
55  
56 supercapacitors dependence on frequency.<sup>32</sup> As shown in Figure 3d, the HAR-NiMoO<sub>4</sub>  
57  
58  
59

60

1  
2  
3  
4 sample exhibits the fastest relaxation time constant ( $\tau_0 = 1.73$  s) compared to that of the  
5  
6 MAR- and LAR-NiMoO<sub>4</sub> samples which are 3.49 s and 6.87 s, respectively. Here, it should  
7  
8 be noted that the fast relaxation time constant implies that the HAR-NiMoO<sub>4</sub> sample can  
9  
10 introduce a fast capacitive response. It can be clearly observed that the phase angle of HAR-  
11  
12 NiMoO<sub>4</sub> at a low frequency of  $f = 0.01$  Hz was about  $-81^\circ$ , which is the closest value to  $-90^\circ$ ,  
13  
14 implying ideal capacitor behavior because of its low electrolyte resistance and fast electrolyte  
15  
16 intercalation.<sup>33</sup> Overall, the electrochemical relationships for the NiMoO<sub>4</sub> electrodes with the  
17  
18 different 1-D morphologies are illustrated in Figure 3e. The HAR-NiMoO<sub>4</sub> electrode  
19  
20 nanostructure not only provides the largest contact sites, which lead to a large density of  
21  
22 electrolyte ions near the surface, but also facilitates more efficient electrochemical reactions  
23  
24 through the highest degree of ion diffusion towards the inside of the electrode. Additionally,  
25  
26 its high electrical conductivity and low surface resistance enable fast charge transfer through  
27  
28 a pseudocapacitor system. Such behavior is strongly correlated to the high capacitance, fast  
29  
30 retention rate and charge transfer mechanism of the HAR-NiMoO<sub>4</sub> electrode.

31  
32  
33 To further demonstrate the potential of the NiMoO<sub>4</sub> electrode for practical  
34  
35 supercapacitor applications, an asymmetric supercapacitor (ASC) was fabricated using the  
36  
37 HAR-NiMoO<sub>4</sub> material as the cathode and active carbon (AC) as the anode. Figure 4a shows  
38  
39 the comparative CV plots of the individual positive and negative electrodes in the ASC at a  
40  
41 scan rate of  $5 \text{ mV s}^{-1}$ . The AC exhibits a typical rectangular electric double-layer capacitor  
42  
43 (EDLC) performance within the range of  $-1.0$  to  $0.0$  V, and the HAR-NiMoO<sub>4</sub> shows  
44  
45 pseudocapacitance behavior within the range of  $0.0$  to  $0.6$  V. Therefore, the AC//HAR-  
46  
47 NiMoO<sub>4</sub> ASC can operate from  $0$  to  $1.6$  V with a wide operating potential. To design the ASC  
48  
49 with the ideal capacitance, the mass of the individual electrodes is optimized according to the  
50  
51 following formula.<sup>34</sup>  
52  
53  
54  
55  
56  
57  
58  
59  
60

$$Q_+ = Q_- \rightarrow \frac{m_+}{m_-} = \frac{C_- * \Delta V_-}{C_+ * \Delta V_+}$$

where  $C_-$  and  $C_+$  are the calculated capacitance of the negative and positive electrodes, respectively, and  $\Delta V_-$  and  $\Delta V_+$  are the operating potential windows of the negative and positive electrodes, respectively. Therefore, on the basis of  $C_-$  and the potential window of the AC electrode, the optimum loading ratio of HAR-NiMoO<sub>4</sub> to AC is 1:3.126.

Figure 4b shows CV curves of the ASC device at various scan rates, ranging from 50 to 5 mV s<sup>-1</sup>. It can be seen that the shape of the CV curves involves both EDLC and pseudocapacitance contribution from the rectangular shape and the redox humps. The CV curves of the ASC are found to maintain a similar profile with increasing scan rates, indicating good capacitive behavior. As shown in the inset of Figure 4c, galvanostatic charge/discharge curves for the ASC were measured at current densities from 1 to 20 A g<sup>-1</sup> in a potential window of 0 to 1.6 V. In addition, the calculated capacitance as a function of the discharge current density is plotted (Supporting Information Figure S4). This device shows good electrochemical performance and the specific capacitance was calculated to be 114.4 F g<sup>-1</sup> at a current density of 1 A g<sup>-1</sup>. Furthermore, the ASC exhibits good cycling stability, retaining up to 82.2 % after 2000 charge-discharge cycles at a current density of 5 A g<sup>-1</sup> (Figure 4c). To compare the energy density and power density with other reported ASCs, the Ragone plots of the AC//HAR-NiMoO<sub>4</sub> ASC were derived in Figure 4d, showing that an energy density of 40.6 Wh kg<sup>-1</sup> and a power density of 16 kW kg<sup>-1</sup> can be achieved. Clearly, the device performance compares favorably with other asymmetric supercapacitors.<sup>35-41</sup> It is shown that the HAR-NiMoO<sub>4</sub> exhibits a high specific capacitance and high ionic and electric transfer rates, along with good electrochemical behavior because: (1) the direct growth of the 1-D NiMoO<sub>4</sub> sample on the Ni foam provides good electron transfer due to the low contact resistance between the active material and the current collector; (2) the highly ordered 1-D

1  
2  
3  
4 nanostructure with a high aspect ratio not only leads to a large diffusion coefficient, but also  
5  
6 results in a large contact area and (3) this gives rises to numerous ion diffusion channels,  
7  
8 thereby inducing a high rate retention response.  
9

## 10 11 12 13 **CONCLUSION**

14  
15 In summary, we have demonstrated that 1-D NiMoO<sub>4</sub> electrodes grown directly onto  
16  
17 a nickel foam have been successfully prepared via a simple supersaturation-controlled  
18  
19 hydrothermal process. The resulting 1-D NiMoO<sub>4</sub> electrodes, each with a different aspect  
20  
21 ratio, can be predictively adjusted by changing the supersaturation states and consequently  
22  
23 the driving force for nucleation and crystal growth. Moreover, electrochemical measurements  
24  
25 indicate that the HAR-NiMoO<sub>4</sub> electrode exhibits the best specific capacitance and superior  
26  
27 rate retention performance such as a large specific capacitance of 1335 F g<sup>-1</sup> at a current  
28  
29 density of 1 A g<sup>-1</sup> with a good rate retention of 66.1 %. We also showed that the AC//HAR-  
30  
31 NiMoO<sub>4</sub> ASC with a wide potential window of 1.6 V exhibits the energy density of 40.7 Wh  
32  
33 kg<sup>-1</sup> and the power density of 16 kW kg<sup>-1</sup> compared to other reported pseudo-capacitive  
34  
35 ASCs. Furthermore, we successfully demonstrated that the HAR-NiMoO<sub>4</sub> electrode provides  
36  
37 a better contact surface area, ion diffusion behavior and enhanced charge transfer kinetics  
38  
39 based on the hierarchical 1-D nanostructure. This deterministic and predictive synthesis  
40  
41 method, which is controlled by adjusting the solubility in a hydrothermal approach, is a  
42  
43 promising technique to producing highly efficient pseudo-capacitive electrodes with 1-D  
44  
45 nanostructures. Such electrodes can easily promote dynamic electrochemical kinetics,  
46  
47 including high Faradaic capacitance, high retention and fast charge transfer rate for practical  
48  
49 pseudocapacitor applications.
