Exploring Malaysia’s Expanding Waistlines
Exploring Malaysia's Expanding Waistlines: the Role of Dietary Public Health Messages and Guidelines in Tackling Overweight and Obesity Issues

ABSTRACT
Overweight and obesity in Malaysia pose serious threats to health. Prevalence has escalated to alarming levels in recent decades despite a multitude of dietary public health messages geared toward obesity prevention and health promotion. Gaps between health messages, messengers, and the public must be identified and closed to effectively combat obesity and overweight. This review article aims to examine dietary public health messages, guidelines, and programmes for the prevention of obesity in Malaysia, and explore potential reasons for the continued rise in prevalence. Dietary public health communication in Malaysia has progressed and improved substantially over the years. However, most messages have been designed for a general audience, with little consideration of differences in physical, social, cultural, and environment backgrounds, and varying levels of comprehension. We offer several recommendations to increase the effectiveness of dietary public health messages in fighting the obesity epidemic, based on a cross-sectoral, place-based approach that recognizes the complexity of underlying causes of obesity.

Keywords: Dietary public health messaging; Obesity; Malaysia; Place-based approach; Cross-sectoral approaches
INTRODUCTION

Obesity has tripled worldwide since 1975, reaching epidemic proportions in both developing and developed countries; as of 2018, 13% of adults are obese and 39% overweight (World Health Organisation (WHO), 2018). Meanwhile, the prevalence of overweight and obesity among children and adolescents has risen from 4% in 1975 to 18% in 2016 (WHO, 2018). The Global Burden of Disease Study (Ng et al., 2013) reported a prevalence of overweight and obesity in Southeast Asia of 22.1% among men and 28.3% among women, with the highest rates in Malaysia at 48.3% and 48.6% for men and women, respectively. The 2015 Malaysian National Health and Morbidity Survey (NHMS) reports similar numbers, estimating the national prevalence of overweight and obesity in adults at 30.0% and 17.7%, respectively, for a total of 47.7% (Institute for Public Health (IPH), 2015). In just two decades, the prevalence of overweight adults has doubled from 16.6%, while obesity has increased four-fold from 4.4% (IPH, 1996).

Malaysia has stated its intent to stop the rise in prevalence of obesity by 2025 (Ministry of Health, 2016). The US$1-2 billion (RM4.26–8.53 billion) spent to combat obesity in 2016—including direct and indirect costs—is equivalent to ~10-19% of national healthcare expenditures (Asia Roundtable on Food Innovation for Improved Nutrition (ARoFIIN), 2016). Public health messages around nutrition—such as those issued by the Ministry of Health—are important as one of a range of efforts for health promotion and obesity. Yet, despite all these actions, obesity rates have continued to rise sharply.

Failure to halt the dramatic increase in the prevalence of overweight and obesity in Malaysia and worldwide has contributed to increased health risks for non-communicable diseases (NCDs) such as diabetes, cardiovascular diseases and cancers and other health issues, leading to higher morbidity and mortality rates. About 8% of total mortality each year is attributed to obesity (Beaglehole et al., 2011). Beyond increased risk of obesity-related chronic diseases and poorer quality of life, the healthcare costs of treating obesity-related disease conditions are rapidly escalating. On average, obese Malaysian males and females lose from 6–11 years and 7–12 years of productive life, respectively (ARoFIIN, 2016).

This paper reviews some of the dietary public health messages, guidelines, and programmes related to overweight and obesity in Malaysia. It identifies possible reasons for the continuing increase in prevalence in the face of abundant public health messages and offers recommendations for a more systemic, place-based approach to slowing and reversing the rise in obesity.
Dietary Public Health Messages

Public Health Messages Related to Nutrition and Obesity in Malaysia

In recent decades, the Malaysia Ministry of Health (MOH) has disseminated numerous public health messages, various sets of nutritional and dietary guidelines, and a series of programmes for the public and for health professionals. The National Plan of Action for Nutrition of Malaysia (NPANM) underlies Malaysia’s strategy for addressing nutritional public health; three versions of the plan have been published since 1996 (National Coordinating Committee on Food and Nutrition (NCCFN), 1996; NCCFN, 2006; NCCFN, 2016).

Table 1 compares the evolving aims of the three NPANM and the evolution of the main areas of focus and facilitating strategies. In the 1996-2000 version, most targets and goals addressed nutritional deficiencies, with no set target for overweight and obesity. At the time, the prevalence of overweight and obesity were 16.6% and 4.4%, respectively (IPH, 1996). By 2003, these had increased to 26.7% and 12.2%, representing nearly two- and three-fold increases, respectively, over just seven years (Azmi et al., 2009). By the launch of the second NPANM in 2006, national prevalence of overweight and obesity among adults was reported at 29.1% and 14.1% (IPH, 2006), with prevalence of NCDs also on the rise. The new plan, accordingly, shifted to meet the new needs, aiming to enhance the nutritional status of the entire population and prevent and control diet-related NCDs. NPANM II set a population-level goal of not more than 30% overweight and not more than 15% obese—targets which were not achieved. In view of the current critical situation, the third and most recent NPANM (2016-2025) has adopted a goal of no further increase in any obesity-related indicators, taking NHMS 2015 data as a baseline. It has also established new indicators, such as abdominal obesity and overweight and obesity among adults above 60 years of age.

Whereas all three plans have taken on such basic goals as ensuring food quality and safety and promoting appropriate diets and healthy lifestyles, focal areas and facilitating strategies for nutrition have evolved in successive NPANMs (Table 1). For example, NPANM I prioritized the prevention and management of infectious diseases, while NPANM II addressed complementary feeding for children and promoted institution-building strategies to strengthen research, development, and capacity. NPANM III recognises the importance of systemic action and local context, promoting multidisciplinary teamwork that builds capacities and empowers communities, the inclusion of food systems frameworks in nutritional strategies, and the development of targeted guidelines for vulnerable groups.

The Malaysian Dietary Guidelines are an important strand of public health messages related to nutrition. Aimed primarily at health care providers, they are “intended to act as a tool for healthy eating promotion towards achieving the National Plan of Action for Nutrition Malaysia” (NCCFN, 2010). Established in 1999 with eight key messages designed to prevent nutritional deficiency and chronic diseases, the Guidelines were revised and updated in 2010, splitting...
several of the original messages to more specifically emphasize, for example, the importance of daily physical activity and fruit consumption, and adding four new guidelines, for a total of fourteen key messages (Figure 1). These changes reflect a better understanding of the origins of obesity and lifestyle-related disease in Malaysia.

Another strand of promotion of public health nutrition encompasses the visually-oriented Malaysian Food Pyramid and Healthy Plate, aimed at the general public. The Malaysian Food Pyramid, modelled on the United States Department of Agriculture (USDA) Food Guide Pyramid (USDA, 1992), was first introduced in 1997 (Tee, 2011) and was intended as a visual guide to assist the public in planning suitable daily food consumption in terms of choices and quantities. In 2016, the Malaysian Healthy Plate, modelled on the USDA MyPlate (Table 2), was released to supplement and in some ways supersede the Food Pyramid. The Malaysian Healthy Plate was heavily promoted to the public through mass media, with a message of suku-suku-separuh (“quarter-quarter-half” in Bahasa Malaysia), referring to fractions of a typical plate: one quarter for meat or fish (protein-based foods), one quarter for grains or carbohydrate-based foods, and half for vegetables and a serving of fruit. The healthy plate concept is highly visual and relatable, and thus easier to understand and put into practice than the more abstract food pyramid.

**Public health spending in Malaysia**

One way to improve the visibility and impact of public health messages is to increase expenditures. While specific data on spending on public health nutrition messages and the costs of nutrition-related disease are difficult to access, evidence from other sources suggests that Malaysia spends far more on treatment than on prevention. For example, according to providers of health services in Malaysia from 1997 to 2015, expenditures on hospitals, ambulatory health care, medicines, and medical appliances greatly exceed the expenditure on health prevention and promotion services (Table 3). Indeed, expenditure on hospital treatment amounted to 50% or more of total health expenditures (including public and private sectors), while less than 5% was spent on provision and administration of public health programmes. Over the same period, similar trends are seen for total health expenditure by the function of health services (Table 4). About 55-65% of expenditure was for services of curative care, whereas just 4-6% was spent on prevention and public health services (Jackson & Shiell, 2017).

While these figures would seem to indicate a low level of public health spending in Malaysia, they are actually fairly high with respect to the average share of total healthcare spending directed to prevention services in OECD countries, in most cases less than 3%. Indeed, health expenditure data must be interpreted with caution. For one, these data measure only expenditures by the health agency, excluding spending by other agencies or other actors that may promote public health. For another, public health spending feeds into the systemic
causes of health and is likely to have non-linear effects. For example, greater spending on
public health promotion, including dietary messages, is likely to extend life expectancy. As
such, individuals encountering the medical system may be older on average, with ailments
that are more expensive to treat. Thus, high expenditures on treatment could potentially be
indicative either of underspending on prevention, or of a highly efficient system of prevention.
More careful analysis of this issue in the Malaysian context would be valuable.

Evolution and controversy in dietary guidelines

Nutritional and dietary guidelines have evolved significantly over the past century, in parallel
with greater understanding of the pathophysiological underpinnings of ill health. Modern
nutritional science began with a strong focus on single-nutrient deficiencies and a concern
over food shortages (Mozaffarian & Forouhi, 2018). Isolation of Vitamin C as a cure for scurvy
in 1932 was followed by the identification of other single-nutrient deficits related with health
issues, such as Vitamin A deficiency with night blindness, Vitamin D with rickets, thiamine
with beriberi, and niacin with pellagra (Mozaffarian & Forouhi, 2018). These relatively simple
successes inspired a reductionist approach to nutritional science, in which the relevant
nutrient for a given disease was identified and a target intake established (Messina et al.,
2001). This information was translated into simple messages for public consumption.

As such diseases were progressively eradicated through advances in nutritional science and
improvements in farming and food production, other issues began to gain in prominence.
Perhaps unsurprisingly, the reductionist approach that had previously been so successful
was applied to these issues. This is readily seen in the 1980 United States Dietary Guidelines
(USDA, 1980), in which the public was instructed to avoid fats (including saturated fat and
cholesterol), which received the lion’s share of the blame for heart disease and the obesity
epidemic. Guidelines for dietary fat were first introduced by the United States and United
Kingdom Governments with the aim of reducing the prevalence of coronary heart disease.
Despite a lack of evidence from randomised controlled trials to support such guidelines, they
have prevailed for 40 years (Harcombe et al., 2015). Malaysian Dietary Guidelines closely
follow the United States guidelines, limiting the intake of foods high in fats and minimising
use of fats and oils in cooking. The Malaysian Food Pyramid also recommends reduced intake
of fat, oils, sugar, and salt, although exact quantities are not mentioned. In the meantime,
the 1980s saw an accelerating increase in obesity and overweight in the US and other
industrialized nations, and the emergence of chronic diseases related to overnutrition
(Mozaffarian, 2017).

Clinicians are now questioning existing food guidelines, which, in addition to adopting a
reductionist perspective that now seems inadequate, are over-reliant on observational studies
and small-scale, short-term interventions. Such studies are susceptible to confounding
factors and errors in self-reported dietary assessments, and thus have questionable relevance
to the real world (Mozaffarian & Forouhi, 2018). One major shift in nutritional thinking has been with respect to the role of fat. Indeed, there is evidence that restricting total fat intake has led to higher carbohydrate intake, resulting in increases in obesity and diabetes (Harcombe, Baker & Davies, 2017). In a systematic review and meta-analysis across low, middle, and high-income countries, Sartorius et al. (2018) concluded that a high-carbohydrate diet, or an increased percentage of total energy intake in the form of carbohydrates, correspondingly increases the odds of obesity. While current opinion is not unanimous, this and numerous other findings question prevailing assumptions and messages on good dietary practices. Such scientific debate over complex nutritional issues is inevitable and ought to produce better knowledge over time. However, it has also contributed to an ever-changing set of dietary recommendations, in which a nutrient is labelled harmful at one point in time, then healthy, then harmful again, causing public confusion and scepticism about scientific claims regarding nutrition (Mozaffarian, 2017). This confusion has been compounded by the accumulation of increasingly complex and nuanced findings which are more difficult to communicate than previous issues around single-nutrient deficiencies.

The controversial role of the food industry in dietary public health messages

Dietary guidelines from governments and advocacy organisations, themselves often muddled, compete with messages from other sources, misinforming and confusing the public. In some cases, the food industry exacerbates this situation, including through promotion of unhealthy products, misleading marketing campaigns, targeting of children and other susceptible groups, corporate lobbying, co-opting of organisations and social media through financial support, and attacks against science and scientists. This may cause increasing distrust towards health professionals and reluctance among the public to accept public health messages (Crossley, 2002).

One prominent example of the influence of the food industry is the aggressive food marketing tactics used to promote junk food consumption among children. For instance, in 2012, the United States fast food restaurant industry spent $4.6 billion on advertising, while combined advertising on so-called “healthier” foods, including milk ($169 million), bottled water (i.e., as an alternative to soft drinks) ($81 million), vegetables ($72 million) and fruit ($45 million) was less than one-twelfth that total (Harris et al., 2013). An average child in the United States watches about 4,700 food-related advertisements per year, of which 84% are for junk food (Harris et al., 2015); equivalent data on food marketing in Malaysia are not available at present, but it seems likely that unhealthy food advertising is equally predominant, if not more so, in this context. While powerful food companies have begun to be criticised and regulated in wealthier nations, less-developed countries remain vulnerable, often lacking junk food marketing policies, in part because they do not have the financial wherewithal to combat the well-resourced food industry. Less-developed countries also generally have a higher
fraction of young people, who are more vulnerable to aggressive marketing tactics, and so will see higher impacts (Kovic et al., 2018).

Another conspicuous example involves sugar-sweetened beverages (SSBs), a top contributor to overall sugar consumption (Baker & Friel, 2014). In industry-sponsored research on the health effects of SSBs (Bes-Rastrollo et al., 2013) and artificial sweeteners (Mandrioli, Kearns & Bero, 2016), the likelihood of conclusions favourable to the sponsor is higher than in non-industry-sponsored studies. Children and adolescents are frequent targets of SSB marketing strategies. This is critical because taste preferences are formed during youth and adolescence—habitual exposure to SSBs leads to unhealthy lifetime dietary habits (Gostin, 2018). Indeed, Brownell and Warner (2009) found that the food industry purposefully targeted youth populations to lock in new generations of consumers, a strategy previously adopted with much success by tobacco companies. SSB consumption is associated with increased waist circumference and other cardiometabolic risk factors independent of physical activity levels and dietary patterns (Loh et al., 2017).

Even when the food industry promotes healthier foods, it is usually done in ways that rely on reductionist messages that are easy to grasp, and that promise to improve health regardless of dietary and lifestyle context. The boom in the vitamin and dietary-supplement industries relies on such marketing, despite a lack of evidence that these products benefit the general population (Jenkins et al., 2018). Similarly, the benefits of other so-called health foods and diets, including juices and gluten-free diets, have frequently been overstated and taken out of the context of the original research (Freeman et al., 2017). Such messages are further reinforced by dietary advice presented in the media, often based on the weakest forms of evidence, and therefore contributing to public misconceptions about food and health (Cooper et al., 2012).

**Cross sector approaches in improving dietary public health messages**

To develop effective messages to combat obesity, it is necessary first to understand the systemic factors that give rise to obesity. Public health research, recommendations, and interventions relating to overweight and obesity prevention and treatment are often based on a simple energy balance model which neglects the complex physiological, behavioural and environmental systems involved (Hafekost et al., 2013). Human physiology is evolutionarily adapted to food-scarce environments and is regulated at several levels by complex, multiple feedback mechanisms that homeostatically regulate energy balance to maintain body weight, making weight loss difficult (Flier, 2017). One example of such regulatory mechanisms is the effect of calorie restrictions on the resting metabolic rate, which decreases energy expenditures in response to reduced energy input (Martin et al., 2011; Martin et al., 2007). Even when weight loss is achieved, compensatory physiological responses to perceived food scarcity during dieting encourage weight gain up to a year later. These physiological
adaptations may be poorly suited to modern human habitats that promote high energy intake and low energy expenditure, characterized by "an essentially unlimited supply of convenient, relatively inexpensive, highly palatable, energy-dense foods", combined with lifestyles that require only minimal levels of physical activity for survival (Hill & Peters, 1998; Peters, 2003; Cohen, 2008). For this reason, Hill and Peters (1998) remarked that the culprit in the increasing prevalence of obesity is the environment that promotes obesity-causing behaviours. Since we are unable to change our physiology, it is the obesogenic environment that must be "cured" to stop and reverse the obesity epidemic (Hill & Peters, 1998). Indeed, while poor dietary habits and inadequate physical activity are known contributing factors to the development of obesity and many NCDs (Booth et al., 2012; Lachat et al., 2013), public health professionals generally agree that genetic, biological, and psychological changes at the individual level are insufficient to explain the rapid modern rise in obesity rates. Therefore, the obesity epidemic must originate in a broader environmental, societal, and policy context (Koplan et al., 2005; Novak & Brownell, 2012; Kumanyika et al., 2013). A systems perspective, capable of recognizing the shape and potential impacts of feedback mechanisms, is required to navigate these issues.

It is important to consider how health messages feed into the physiological-environmental system that underlies obesity and the conditions necessary for information to be effective in this context. Public health messages aimed at reducing obesity must transcend an implied information-deficit model which assumes that supplying basic knowledge on nutrition is enough to achieve change. Rather, such messages are best understood as attempts to convince a very broad, diverse audience to make behavioural and lifestyle changes that are both difficult and at odds with their contextual cues and incentives. This differs from traditional marketing, which delivers uncomplicated, attractive messages to targeted audiences, and it should be no surprise that health messages achieve lower response rates (Kelly & Barker, 2016). This problem is compounded when health sector messages compete against those from commercial food and "health" industries. The latter promote simpler products while also generating profits, allowing the private sector to far outspend the health sector in this context. At present, guidelines for health promotion focus on communication techniques, such as limiting the number of ideas to avoid confusing readers (US Department of Health and Human Services, 2006), reducing jargon and technical language, using active voice and conversational style, and providing concrete examples (Wigington, 2008). Indeed, beyond failing to enable healthier behaviour, poorly crafted messages may contribute to negative self-perceptions and, in the process, generate more pervasive problems (Penney & Kirk, 2015; Rudolph & Hilbert, 2017). Yet, while important, such techniques do not address the broad range of obstacles in the messaging environment.

Because knowledge is necessary, but not sufficient, to change behaviour (Worsley, 2002; Patton, 2008), messages targeted at individual behaviour need to be accompanied by
strategies that create contexts where people are encouraged or naturally predisposed to act on these messages. Therefore, health communicators also need to consider how to influence the key actors who shape these environments. For example, the failure of town and transport planners to consider health issues in, for instance, the design of parks, recreation centres, and other public spaces has been seen as a cause of the rise in the prevalence of obesity, NCDs, and sedentary behaviour (WHO, 2004). A wide range of stakeholders—both public and private, at federal, state, and municipal levels—must play a role in halting the obesity crisis. Physical, social and cultural environments associated with work (Schulte et al., 2007; Hyun & Kim, 2018), food (Mattes & Foster, 2014; Steeves, Martins & Gittelsohn, 2014), family (González Jiménez et al., 2012; Huang et al., 2017) and community (Yoon & Kwon, 2014) all enable and constrain the individual choices and behaviours that affect obesity. For example, in Malaysia, the widespread practice of serving sweet and savoury snacks at morning and afternoon tea at functions, conferences, and meetings enables over-consumption of food and cements frequent eating as a social norm. Working hours (Cheong et al., 2010), availability of fast food (Abdullah et al., 2015), and school nutrition (SCHEMA, 2018), among other factors, also play key enabling/constraining roles in Malaysia. Health messages and other policy interventions must target these physical, social and cultural environments, connecting actors and creating new feedback links to reshape systems in ways that promote health.

Within Malaysia there is such heterogeneity in sociocultural environments that both the message and the way it is communicated must be tailored to local contexts, highlighting the importance of place-based thinking. Indeed, rates of obesity in Malaysia vary by geographical locations and ethnicity (IPH, 2015), and these differences are greater than can be explained by simple urban/rural differentiation. Varied diets and cultures (Nurul Fadhilah, Teo & Foo, 2016; Lee, 2017) imply that the changes needed to achieve healthy and socially-acceptable eating habits and lifestyles may be very different for different ethnic and social groups. Similarly, identifying the appropriate form of messages and messengers for a target group is important and requires local knowledge (WHO, 2017). Acquiring and using this knowledge depends on early and consistent community engagement and participation in both research and policy processes, before problems and potential solutions are formulated (Bodison et al., 2015). Accounting for the particularities of place will better allow for the development of targeted and tailored messages, programmes, guidelines, and interventions to meet age, gender, culture, socioeconomic, and geographical needs.

**Recommendations for improving dietary public health messages in Malaysia**

To make dietary health messages in Malaysia more effective vehicles for change, we suggest three broad strategic actions: building capacity and receptivity for complex ideas, mobilising a diversity of messengers, and implementing key policy interventions that target the food environment.
Creating receptivity for complex ideas

While health messages should be simple, to enhance communication, many important dietary messages are inherently complex. In keeping with the systems view of dietary public health outlined above, various actions could be taken to improve the efficacy of messages in Malaysia without making them simplistic. First, an ability to understand complex messages needs to be developed within the community. Reductionist thinking continues to dominate in science curricula, shaping the types of evidence people expect to see and are receptive to. Systems thinking, complexity, and holistic approaches to problem-solving could be introduced in school science curricula, for example in relation to biology, metabolism, and nutrition (Fardet & Rock, 2014). In the long term, exposure to these concepts can create an ability to understand the interconnected concepts necessary to address present and future nutrition challenges. While rewriting basic curricula will take years, if not decades, the cost of nutrition-related diseases—to say nothing of other complexity-related societal challenges—warrants such an effort. A body of evidence suggests that such concepts can be understood by lay people, practitioners, and students, given appropriate pedagogy (SCHEMA, 2018; Newell & Siri, 2016). Second, it is still necessary to simplify complex messages, without making them simplistic, to meet existing capacities for comprehension. The Malaysia Healthy Plate is a good example of such translation. Further successes will depend in part on the involvement of local community leaders and members, as called for in NPANM III.

Mobilising diverse messengers through a multi-sector approach

As food is deeply tied to a wide range of social and cultural values, a multi-sector approach that addresses diet from a broader set of perspectives could increase effectiveness of dietary messages. While the Ministry of Health has actively fought overweight and obesity, gaps remain that could be filled by other ministries which have historically been less engaged on this issue, but whose activities and responsibilities have consequences for urban health. These would include the Ministries of Urban Well-being, Housing and Local Government; Education; Finance; Transport; Women, Family and Community Development; Agriculture and Agro-Based Industry; and Youth and Sports. Many of these government ministries have access to different community organisations, and their contacts could be used to deliver messages and implement interventions specific to target specific communities. A good example is the KOSPEN programme, a collaboration between the Ministry of Health and the Ministry of Rural Development to recruit and mobilise community health volunteers (Ministry of Health, 2016).

The food industry is a key player in shaping the food environment and has often (though not always) done so in ways that undermine health messages. So-called “influencers”—public health activists, celebrity nutritionists, politicians, and food bloggers, to name a few—have the potential to shape societal paradigms and purchasing choices, thus influencing changing industry practices (Sbicca, 2012; Byrne, Kearney & MacEvilly, 2017; Johnstone & Lindh,
The Malaysian health sector should consider how to engage with such influencers, to encourage them to use messages based on the best available evidence. Direct engagement with the food industry would be beneficial. Indeed, the United States Centers for Disease Control and Prevention (CDC) acknowledged that the food industry’s “expertise, reach, and innovation can help address challenges in food production, formulation, and distribution; facilitate greater innovation for public good; and build capacity” despite the potential for bias (CDC, 2018). Nevertheless, partnerships between the health sector and the food industry must be governed by clear principles to avoid actions and perceptions that would compromise health promotion goals (Mozaffarian, 2017; CDC, 2018; Freedhoff & Hébert, 2011).

Complementing Messages with Regulatory and Fiscal Policy

Regulation is an important mechanism for shaping the nutrition information environment to catalyse desired behaviours. Yet, ensuring the accuracy and credibility of messages can be challenging. A 2010 WHO resolution, endorsed by 192 United Nations member states, urged regulation of food and beverage marketing to children to address the childhood obesity epidemic (WHO, 2010). However, many countries rely on food industry self-regulation in marketing (Hawkes & Lobstein, 2011). Malaysia, for example, has implemented food advertising regulations such as banning fast-food advertisements on children’s television programmes, yet the Malaysian Ministry of Health has also endorsed self-regulation in the food industry. A prominent example is the Malaysian Food Manufacturing Group’s “Responsible Advertising to Children – Malaysia Pledge” (Food Industry Asia, 2012; Food Industry Asia, 2013), the effects of which have not been studied. In some cases, the source of funding for nutritional research creates likely conflicts of interest. For example, the Ministry of Health endorsed a popular malt drink, produced by a large multi-national company and marketed as a nutritious “Healthier Choice”. In 2018, a national controversy erupted over this drink’s sugar content (Thiagarajan, 2018), while it simultaneously came to light that the company in question funds substantial nutrition research in Malaysia. This research included a study claiming correlations between consumption of malt drinks, physical activity and micronutrient intake among Malaysian children (Hamid et al., 2015). Such findings may be legitimate; for example, there might be cultural factors in this population associated with both malt-drink consumption and physical activity that explain the observed correlations. Nevertheless, results like this raise suspicion of conflicts of interest when there are perceived lack of transparency or external accountability (Mozaffarian, 2018). Indeed, such situations can also create suspicion of other otherwise non-controversial results. Advertising regulations and Ministry of Health endorsements must be seen to be based on reliable and unbiased research to maintain the credibility of health promotion information.

Subsidies and taxes can also reinforce or subvert health messages and the capacity of the target audience to act upon them. They must be considered in the local economic and political context. For example, the WHO recommends restricting sugar consumption to less than 10%
of total energy intake, and advocates a further reduction to below 5% (WHO, 2015). Yet, sugar consumption worldwide exceeds these levels; indeed, Malaysian per-capita sugar consumption is among the highest in the world (11-19 tsp/day) (Swarna Nantha, 2014; Amarra, Khor & Chan, 2016); this is approximately 9-15% of total intake, assuming 2000kcal/day. One response has been to tax products with high sugar content, such as SSBs, and this has been effective in some contexts (Colchero et al., 2017; WHO, 2017; Gostin, 2018).

Yet, in Malaysia, the price of sugar is perceived to broadly affect food prices, making it an important political issue on a wider scale. In fact, sugar was subsidised until 2013, and Malaysia still maintains a price ceiling on sugar, with politicians continuing to advocate subsidies (anon, 2017) or lowering this ceiling (Ganeshwaran, 2018). At the same time, SSB taxes have been studied by the Ministry of Health in the past, and have been proposed again recently in response to rising diabetes rates (anon, 2018). The contrasting positions on sugar prices and SSB taxes highlight the conflicting priorities between the trade and health arms of the Malaysian Government, illustrating the need for coordinated policy and mainstreaming of health in all government action.

Subsidies can provide an effective complement to taxation in promoting better nutrition. In neighbouring Singapore, the Health Promotion Board has coupled messages on the consumption of brown rice and other whole grains with subsidies for these staple ingredients in the food service industry (Singapore Health Promotion Board, 2018). High consumption of white rice has been shown to increase Type II diabetes risk, particularly in Asian populations (Hu et al., 2012) but white rice is culturally far more popular, perceived as finer and more desirable. Furthermore, brown rice carries a higher price tag, in part due to economies of scale. This subsidy attempts to shift private sector practice to reinforce health messages on rice consumption. Such strategies are worth exploring in Malaysia, where many consumers have high price-sensitivity, and the direct cost of diabetes alone is estimated at RM 2.04 billion annually (Feisul Idzwan et al., 2017).

CONCLUSION

Being overweight or obese increases the risk of many health problems and imposes significant economic and social costs on society. The alarmingly high prevalence of overweight and obesity in Malaysia thus represents a serious threat, not only to the health of its citizens, but to achieving other societal aspirations, including the United Nations Sustainable Development Goals (United Nations, 2015). This article reviewed dietary public health messages and guidelines connected to overweight and obesity issues and examined gaps in some of these messages. Although dietary public health communication in Malaysia has progressed and improved substantially over the years, most messages have been designed for a general audience, with little consideration of differences in physical, social, cultural, and environment backgrounds, and varying levels of comprehension. Such messages also compete with promotional information disseminated by profit-making food and “health” industries. We suggest that cross-sector approaches grounded in an appreciation of local context can offer
solutions to make dietary health messages more effective, in particular by increasing understanding of the complex determinants of obesity, taking advantage of the systemic roles of multi-sector stakeholders, and implementing specific policy interventions that target the Malaysian food, social-cultural, and environmental contexts.

Evolution of dietary guidelines in Malaysia
(Malaysia Dietary Guidelines 1999 and 2010)

1. Eat a variety of foods within your recommended intake.
3. Be physically active every day.
4. Eat adequate amount of rice, other cereal products (preferably whole grain) and tubers.
5. Eat plenty of fruits and vegetables every day.
6. Consume moderate amounts of fish, meat, poultry, egg, legumes and nuts.*
7. Consume adequate amounts of milk and milk products.*
8. Limit intake of foods high in fats and minimise fats and oils in food preparation.
9. Choose and prepare foods with less salt and sauces.
10. Consume foods and beverages low in sugar.
11. Drink plenty of water daily.
12. Practise exclusive breastfeeding from birth until six months and continue to breastfeed until two years of age.
13. Consume safe and clean foods and beverages.*
14. Make effective use of nutrition information on food labels.*

*Key messages that were introduced in the Malaysia Dietary Guidelines 2010

Figure 1. Evolution of dietary guidelines in Malaysia
Table 2. Comparison of the Malaysian Food Pyramid and Malaysian Healthy Plate

<table>
<thead>
<tr>
<th>Malaysian Food Pyramid</th>
<th>Malaysian Healthy Plate 2016</th>
</tr>
</thead>
</table>

The pyramid consists of four levels (from base to the top of the pyramid):
- Level 1 (base) – Cereals, cereal products, and tubers: Eat adequately, 4-8 servings/day
- Level 2 - Vegetables: Eat plenty, 3 servings/day
- Level 2 - Fruits: Eat in moderation, 1-3 servings/day
- Level 3 - Milk and milk products: Eat in moderation, ½ - 2 servings of poultry/meat/egg/day; 1 serving of fish/day, ½ - 1 serving of legumes/day
- Level 4 (top) – Fat, oil, sugar, salt: Eat less (no quantity recommended)

"Quarter-Quarter-Half" Concept
- Fill a quarter of a plate (round) with rice, noodles, bread, cereals, cereal products, or tubers, preferably wholemeal (carbohydrate-based).
- Fill another quarter of the plate with fish, chicken, meat, or beans/legumes (protein-based).
- Fill half of the plate with vegetables and one serving of fruit.
- Complete the meal with a glass of plain water or a non-sweetened beverage, milk, or milk product.

Additional recommendations:
- Eat three (3) main healthy meals a day.
- Eat one to two healthy snack in between mealtimes if needed.
- Make at least half of your overall cereal and cereal products intake as wholemeal options.
- Eat non-fried and non-coconut milk based dishes everyday.
- Eat home-cooked foods more frequently.
