Fitting Cylinders Computation with an Application to Measuring 3D Shapes

Joviša Žunić^{*} and Padraig Corcoran[†]

Abstract

This paper observes a fitting cylinders problem for 3D shapes. The method presented defines two cylinders that fit well with the shape considered. These cylinders are easy and fast to compute. Would the 3D shape considered be digitized, i.e. represented by the set of voxels, the computation is asymptotically optimal. Precisely, the time required for the computation is $\mathcal{O}(N)$, where N is the number of voxels inside the shape.

Next, we show how these fitting cylinders can be used to measure 3D shapes. More precisely, we define a new 3D shape measure that numerically evaluates how much a shape given looks like a cylinder. Interestingly, both fitting cylinders have to be used to define such a measure - just one of them is not sufficient. The new measure is invariant with respect to translation, rotation, and scaling transformations, and ranges over the interval $[0; 1]$, and takes the value 1 if and only if the shape considered is a perfect cylinder. It is robust and simple to compute.

Key-words: Fitting 3D shapes, fitting objects by cylinders, 3D moments, invariants, object fitting efficiency, 3D shape measure.

1 Introduction

This paper deals with shape fitting and shape measurement problems - two recurrent problems in pattern recognition, image processing, and computer vision. More precisely, we deal with fitting cylinders and cylinderness measure for 3D shapes. Being one of the basic shapes that appear frequently in different domains, from medicine to the industry, a spectrum of the problems related

24 to cylindrical shapes were already studied in the literature. Just to mention the cylindrical surface
25 fitting problems, [22, 23, 30, 32], segmentation problem [17], parameters estimation problem [7], or
26 the registration problem [2], for an illustration.

27 The research related to the 3D shape based object analysis was not so intensive at the beginning
28 of a usage of computers for manipulation and processing of image based data. It becomes more
29 important due to the developments in the 3D image technologies, and a 3D data availability.
30 Initially, the shape characterization based on the 3D moment invariants has been done – [14, 16, 28].
31 A study on an analogue of the famous Hu moment invariants [12, 16] that has resulted in designing
32 a compactness measure [36] for 3D shapes, and latter on recovering ellipsoidness measures [15, 35],
33 is another set of problems that have been considered. The cubeness [19], vesselness [8], rectilinearity
34 [13], Minkowski compactness measure [18], are other examples of the numerical characterizations
35 of the 3D shapes.

36 So far, most shape measures are developed related to a study of two-dimensional shape proper-
37 ties. Most popular shape properties have allocated multiple shape measures. Just to mention two
38 of them, ellipticity [1, 21, 29, 38] and circularity [10, 24, 34]. Of course, there are many more shape
39 properties that have been evaluated numerically: squareness [27], elongation [33, 37], anisotropy
40 [25], bizarreness [3], and so on. There are also measures particularly related to the curve properties
41 [9], curve temperature [6], linearity [26], and many more.

42 In this paper we introduce a new 3D shape measure, herein named *shape cylinderness measure*.
43 This is a global shape descriptor, in sense that all the shape points are used for the computation –
44 not only the boundary ones. The 3D shape cylinderness measure evaluates how much the object
45 considered looks like a cylinder. The new measure ranges over the interval $[0, 1]$, takes the value 1
46 if and only if the shape measured is a cylinder. Also, it is invariant with respect to the translations,
47 rotations, and scaling transformations. In addition, the new measure is simple to compute and is
48 robust.

49 The paper is organized as follows: The next section includes the basic notations and definitions
50 used in the paper. Section 3 establishes a theoretical framework for the definition of the new fitting
51 cylinders, for 3D shapes. It has turned out that our method leads to two fitting cylinders, for a
52 given 3D shape, for a small exception for almost spherical shapes. The computation is efficient,
53 and would voxalized data are used is asymptotically optimal.

54 In the Section 4, we use these fitting cylinders to design a new 3D shape measure, numerical
55 evaluation how much a given set looks like a cylinder¹. A formal definition of the new measure is
56 given there, as well.

57 Experimental illustrations are in the Section 5. The same section includes a modification of
58 the cylinderness measure from the Section 4. Such a modification enables a simpler computation.

¹Here in, by a *cylinder* we mean a 3D body, not a cylindrical surface.

59 Concluding remarks are in the last section.

60 2 Notations and Definitions

61 We start with the basic notations and definitions, used in this paper.

- So called, *geometric moments*, $m_{p,q}(S)$, of a 3D region/shape S are defined as follows

$$m_{p,q,r}(S) = \iiint_S x^p y^q z^r dx dy dz. \quad (1)$$

- The moments $m_{0,0,0}(S)$, $m_{1,0,0}(S)$, $m_{0,1,0}(S)$, and $m_{0,0,1}(S)$ are used to define the shape centroid, $(x_c(S), y_c(S), z_c(S))$, formally defined as

$$(x_c(S), y_c(S), z_c(S)) = \left(\frac{m_{1,0,0}(S)}{m_{0,0,0}(S)}, \frac{m_{0,1,0}(S)}{m_{0,0,0}(S)}, \frac{m_{0,0,1}(S)}{m_{0,0,0}(S)} \right) \quad (2)$$

64 Obviously, if the shape in question is assumed to be of a unit volume, i.e. $m_{0,0,0}(S) = 1$, then
 65 the point $(m_{1,0,0}(S), m_{0,1,0}(S), m_{0,0,1}(S))$ coincides with the centroid of S .

- To simplify theoretical derivations and without loss of generality, we will assume that all the shapes considered will be translated such that their centroid coincides with the origin. Thus,

$$(x_c(S), y_c(S), z_c(S)) = (0, 0, 0) \quad (3)$$

68 would be assumed even though has not been mentioned.

- In our derivations we will use a well known quantity, $J(S)$ [16], defined as

$$J(S) = \frac{m_{2,0,0}(S) + m_{0,2,0}(S) + m_{0,0,2}(S)}{m_{0,0,0}(S)^{5/3}}, \quad (4)$$

70 assuming that the centroid of S and the origin coincide. $J(S)$ is invariant with respect to
 71 translations, rotations, and scaling transformations. Actually, $J(S)$ might be seen as a 3D
 72 analogue of the first Hu moment shape invariant [12], commonly used in shape based object
 73 analysis tasks.

- By a *cylinder* $C(h, a)$ we mean a 3D body bounded by the two hyper-planes z_1 and z_2 , and a circular oval w – all three cylinder bounding surfaces are defined as follows (for an illustration see Fig.1):

$$\begin{aligned} z_1 &= \left\{ (x, y, z) \mid z = \frac{h}{2} \right\}, \\ z_2 &= \left\{ (x, y, z) \mid z = -\frac{h}{2} \right\}, \\ w &= \{ (x, y, z) \mid x^2 + y^2 = a^2 \}. \end{aligned} \quad (5)$$

77 In other words,

$$C(h, a) = \left\{ (x, y, z) \mid |z| \leq \frac{h}{2}, x^2 + y^2 \leq a^2 \right\}. \quad (6)$$

78 If the cylinder $C(h, a)$ has the volume equal to 1, then $a = \frac{1}{\sqrt{\pi \cdot h}}$. In other words, $C(h, a)$ is
 79 dependent on a single parameter h . For a shorten denotation we will write $C(h)$, instead of
 80 $C(h, a)$. Thus,

$$C(h) = C(h, a) = C\left(h, a = \frac{1}{\sqrt{\pi \cdot h}}\right). \quad (7)$$

81 The parameters h and a would be called the *height* and *base radius*, of the cylinder $C(h, a)$,
 respectively.

Figure 1: A part of a cylinder, from the first octant, positioned as defined by their surface equations given as in (5).

82

83 3 Fitting Cylinders for 3D Shapes

84 In this section, first we develop a theoretical framework needed to compute two fitting cylinders,
 85 for a given 3D shape. A formal definition for these two cylinders follows easily from the theoretical
 86 observations made. Experimental illustrations are in a separate subsection.

87 We start from the formulas for the volume $Vol(C(a, h))$ of the cylinder $C(a, h)$ and for the
 88 invariant $J(C(a, h))$ (as given in (4)). These are as follows:

$$Vol(C(h, a)) = \pi \cdot a^2 \cdot h, \quad (8)$$

$$J(C(h, a)) = \frac{1}{(\pi \cdot h \cdot a^2)^{2/3}} \cdot \left(\frac{h^2}{12} + \frac{a^2}{2} \right).$$

89 The expression for $Vol(C(a, h))$ is trivial, while a derivation of expression for $J(C(h, a))$ follows

$$J(C(h, a)) = \frac{1}{(\pi \cdot h \cdot a^2)^{5/3}} \cdot \iiint_{C(a, h)} (x^2 + y^2 + z^2) dx dy dz \quad (9)$$

$$= \frac{1}{(\pi \cdot h \cdot a^2)^{5/3}} \int_0^{2\pi} \int_0^a \int_{-h/2}^{h/2} (\rho^3 + \rho z^2) d\phi d\rho dz \quad (10)$$

$$= \frac{2 \cdot \pi}{(\pi \cdot h \cdot a^2)^{5/3}} \cdot \int_0^a \int_{-h/2}^{h/2} (\rho^3 + \rho z^2) d\rho dz \quad (11)$$

$$= \frac{2 \cdot \pi}{(\pi \cdot h \cdot a^2)^{5/3}} \cdot \int_0^a \left(h\rho^3 + \frac{\rho}{12} h^3 \right) d\rho \quad (12)$$

$$= \frac{\pi \cdot h \cdot a^2}{(\pi \cdot h \cdot a^2)^{5/3}} \cdot \left(\frac{h^2}{12} + \frac{a^2}{2} \right) \quad (13)$$

$$= \frac{1}{(\pi \cdot h \cdot a^2)^{2/3}} \cdot \left(\frac{h^2}{12} + \frac{a^2}{2} \right). \quad (14)$$

90 If we set the volume of $C(h, a)$ to be equal to 1, we have the following two equivalent equalities,
91 satisfied by $J(C(h, a))$

$$J\left(C\left(h = \frac{1}{\pi \cdot a^2}, a\right)\right) = \frac{a^2}{2} + \frac{1}{12 \cdot \pi^2 \cdot a^4}, \quad (15)$$

$$J\left(C\left(h, a = \frac{1}{\sqrt{\pi \cdot h}}\right)\right) = \frac{1}{2 \cdot \pi \cdot h} + \frac{h^2}{12}.$$

92 We will exploit the second equality from (15), and use the notations from (7), to receive the
93 following equality satisfied by h . form:

$$\pi \cdot h^3 - 12 \cdot \pi \cdot J(C(h, a)) \cdot h + 6 = 0. \quad (16)$$

94 3D shape moment invariant $J(S)$ is a distinct and natural 3D shape characteristic. Looking at
95 the formula in (4), it can be concluded (for more details see [35, 36]) that $J(S)$ evaluates the average
96 squared distance of the points from S to the centroid of S . As such, the quantity $J(S)$ is invariant
97 with respect to the translations, rotations, and scaling transformations. Thus, a use of isometric
98 transformations, to place the objects compared into a desirable position, is not necessary. This is
99 why we decide to exploit the invariant $J(S)$, and the related equation in (16), for the computation
100 of the shape fitting cylinders. More precisely, we start from

$$\pi \cdot h^3 - 12 \cdot \pi \cdot J(S) \cdot h + 6 = 0 \quad (17)$$

101 and compute the parameters h , that uniquely (up to isometric transformations) define the corre-
102 sponding unit volume cylinder $C\left(h, a = \frac{1}{\sqrt{\pi \cdot h}}\right)$. It turns out that, with small exceptions, there
103 are two parameters h , satisfying the conditions above.

104 The equation in (17) is a cubic equation in h . The number of solutions (roots) of (17) depends
 105 on the, so called, discriminant Δ , as follows:

- 106 • if $\Delta > 0$, the equation in (17) has three real solutions;
- 107 • if $\Delta = 0$, the equation in (17) has one multiple real solution;
- 108 • if $\Delta < 0$, the equation in (17) has one real solution and two complex ones.

109 In the case observed here, the discriminant Δ is as follows

$$\Delta = 108 \cdot \pi^2 \cdot (64 \cdot \pi^2 \cdot J(S)^3 - 9). \quad (18)$$

110 Of course, we are interested in the positive values of h , that are solutions of the equation in
 111 (17). This is because h has a clear geometric interpretation – the cylinder height (see Fig.1).

112 The quantity $J(S)$ is not bounded above (i.e. $J(S)$ can be arbitrarily large) but reaches its
 113 minimal possible value if S is a 3D ball (i.e. a shape bounded by a perfect 3D sphere) [35, 36].
 114 The following estimate gives the best possible lower bound [35, 36]:

$$J(S) \geq \frac{3^{5/3}}{5 \cdot (4\pi)^{2/3}} \approx 0.2309, \quad (19)$$

115 with the equality, in (19), if and only if S is a 3D ball [35, 36].

116 Thus, an immediate observation would say, the discriminant Δ (for an arbitrary shape S)
 117 defined as in (18), is inside the interval

$$\begin{aligned} & \left[108 \cdot \pi^2 \cdot \left(64 \cdot \pi^2 \cdot \left(\frac{3^{5/3}}{5 \cdot (4\pi)^{2/3}} \right)^3 - 9 \right), \infty \right) \\ & \left[108 \cdot \pi^2 \cdot \left(\frac{4 \cdot 3^5}{125} - 9 \right), \infty \right) \\ & \approx [-1304.7, \infty). \end{aligned} \quad (20)$$

118 So, observing the range of $J(S)$ only, all three situations $\Delta > 0$, $\Delta = 0$, and $\Delta < 0$, would be
 119 possible.

120 **Note 1** *The lower bound for $J(S)$, if S is a perfect cylinder is, of course, larger than the lower*
 121 *bound in (19). If we start from the second equality in (15), we have*

$$\frac{dJ(C(h, a))}{dh} = \frac{-1}{2 \cdot \pi \cdot h^2} + \frac{h}{6}. \quad (21)$$

So, the equation $\frac{dJ(C(h, a))}{dh} = 0$ has a single solution: $h = \sqrt[3]{\frac{3}{\pi}}$. Further, since

$$\lim_{h \rightarrow 0} J(C(h, a)) = \lim_{h \rightarrow \infty} J(C(h, a)) = \infty,$$

122 we deduce (taking into account the scaling invariance of $J(S)$) that the minimum value of the $J(S)$,
 123 if S is a perfect cylinder, is reached for $h = \sqrt[3]{\frac{3}{\pi}}$ and is calculated as follows

$$\begin{aligned}
 & \min\{J(C(h, a)) \mid C(h, a) \text{ is a cylinder}\} \\
 = & J\left(C\left(h = \sqrt[3]{\frac{3}{\pi}}, a = \frac{1}{\sqrt[6]{3 \cdot \pi^2}}\right)\right) \\
 = & J(C(h \approx 0.9847, a \approx 0.5685)) \\
 = & \frac{3}{4 \cdot \sqrt[3]{3 \cdot \pi^2}} \approx 0.2424. \tag{22}
 \end{aligned}$$

124

125 **Note 2** There is a short interval

$$I = \left[\frac{3^{5/3}}{5 \cdot (4\pi)^{2/3}}, \frac{3}{4 \cdot \sqrt[3]{3 \cdot \pi^2}} \right] \approx [0.2309, 0.2424] \tag{23}$$

126 such that $J(C(h)) \notin I$, for all h . The shapes S whose $J(S)$ values are inside I are nearly spherical
 127 and all of them are best matched (in terms considered here) by the cylinder $J\left(C\left(\frac{1}{\sqrt[6]{3 \cdot \pi^2}}, \sqrt[3]{\frac{3}{\pi}}\right)\right)$,
 128 as described in (22). This is not of a great importance for us now, since this work is aimed to
 129 analyze more ‘elongated’ 3D shapes. For such, ‘not nearly spherical’, shapes $J(S)$ is larger than
 130 $\frac{3}{4 \cdot \sqrt[3]{3 \cdot \pi^2}} \approx 0.2424$.

131 So far, we have shown that there are just a finite number (up to three) candidates for the
 132 cylinders that fit well with the shape considered. Next, we show even more, that the method does
 133 offer exactly two fitting cylinders, for any shape S with $J(S) \notin I$ (see (23)). We show this in two
 134 steps (the next two items).

135 • In the case of $\Delta < 0$, not all the three solutions of the equation in (17) can be positive.
 136 Indeed, if h_1, h_2 , and h_3 , are roots of the equation in (17) then

$$\begin{aligned}
 & \pi \cdot h^3 - 12 \cdot \pi \cdot J(S) \cdot h + 6 \\
 = & \pi \cdot (h - h_1) \cdot (h - h_2) \cdot (h - h_3), \tag{24}
 \end{aligned}$$

137 and further

$$\begin{aligned}
 & -h_1 - h_2 - h_3 = 0, \\
 & h_1 \cdot h_2 + h_1 \cdot h_3 + h_2 \cdot h_3 = -12 \cdot J(S), \\
 & -\pi \cdot h_1 \cdot h_2 \cdot h_3 = 6. \tag{25}
 \end{aligned}$$

138 However, if $h_1 \geq 0, h_2 \geq 0$, and $h_3 \geq 0$ is assumed, then $h_1 \cdot h_2 + h_1 \cdot h_3 + h_2 \cdot h_3 > 0$.
 139 Consequently, the second equality $h_1 \cdot h_2 + h_1 \cdot h_3 + h_2 \cdot h_3 = -12 \cdot J(S)$, in (25), would
 140 contradict to the fact that $J(S) > 0$, for any shape S .

141 • Similarly to the above, we deduce a contradiction if we assume only one root, let say h_1 ,
 142 in (17) to be positive. Then, it must be $h_2 \cdot h_3 > 0$. This further would contradict to
 143 $-\pi \cdot h_1 \cdot h_2 \cdot h_3 = 6$, (from (25)), since the left part of the last equality would be a negative
 144 number, i.e. cannot be equal to 6.

145 Thus, exactly two zeros of the equality in (17) are positive. More details are in the following note.

146 **Note 3** If two zeros, let say h_1 and h_2 , in the polynomial in (24) are equal then $h_1 = h_2 = \sqrt[3]{\frac{3}{\pi}}$. In
 147 such a case, the third zero h_3 is negative and satisfies $h_3 = -2 \cdot \sqrt[3]{\frac{3}{\pi}}$. In other words, this is the only
 148 case where the fitting cylinders coincide. Such a fitting cylinder is $C \left(h = \sqrt[3]{\frac{3}{\pi}}, a = \frac{1}{\sqrt[6]{3 \cdot \pi^2}} \right)$,
 149 i.e. the cylinder that has the minimal possible value of the 3D invariant $J(S)$ (see Note 1 and
 150 derivation of the equality in (22)).

151 Now, since we know that the number of solutions of the equation in (17) is exactly two, we give
 152 the following definition of the cylinders fitting with a given 3D shape.

153 **Definition 1** Let a 3D shape, with $J(S) \notin I$, be given. Then we define two fitting cylinders

$$C(h_l) = C \left(h_l, a_s = \frac{1}{\sqrt{\pi \cdot h_l}} \right) \quad (26)$$

$$C(h_s) = C \left(h_s, a_l = \frac{1}{\sqrt{\pi \cdot h_s}} \right) \quad (27)$$

for the shape S . The parameters h_l and h_s are solutions of the following equation (see (17))²:

$$\pi \cdot h^3 - 12 \cdot \pi \cdot J(S) \cdot h + 6 = 0.$$

154 We assume $h_l > h_s$ (i.e. indices l and s stand for ‘long’ and ‘short’, respectively).

155 3.1 Fitting Cylinders Examples

156 We proceed with several examples that include shapes selected randomly and their corresponded
 157 fitting cylinders, computed based on the equation in (17). These examples are in Fig.2. Four 3D
 158 shapes are selected randomly from the well known *McGill 3D Shape Benchmark* shape data set
 159 [20]. They are displayed in the first row in Fig.2, and their names, as given in the data set [20],
 160 are immediately below them. Their corresponding fitting cylinders are displayed below them³,

²This is a cubic equation, whose solutions can be given in an explicit (but slightly complicated) form, by using Cardano’s result.

³Notice that the fitting cylinders, in Fig.2, are presented by their oval surfaces only – not as 3D closed bodies, as they are. This has been done for a better visualization purpose.

 teddy1	 hands10	 dolphins6	 snakes 24
 $h_l = 1.9859, a_s = 0.4004$ $\frac{h_l}{2 \cdot a_s} = 2.4802$	 $h_l = 2.7019, a_s = 0.3432$ $\frac{h_l}{2 \cdot a_s} = 3.9359$	 $h_l = 2.4681, a_s = 0.3591$ $\frac{h_l}{2 \cdot a_s} = 3.4363$	 $h_l = 3.6180, a_s = 0.2966$ $\frac{h_l}{2 \cdot a_s} = 6.0988$
 $h_s = 0.4027, a_l = 0.8891$ $\frac{h_s}{2 \cdot a_l} = 0.2265$	 $h_s = 0.2403, a_l = 1.1509$ $\frac{h_s}{2 \cdot a_l} = 0.1044$	 $h_s = 0.2814, a_l = 1.0636$ $\frac{h_s}{2 \cdot a_l} = 0.1323$	 $h_s = 0.1404, a_l = 1.5057$ $\frac{h_s}{2 \cdot a_l} = 0.0466$

Figure 2: Four shapes, selected randomly, from [20] data set are in the first row. Their fitting cylinders are given below them, together with the positive zeros h_l and h_s , computed from the related equality in (17). The parameters $a_s = 1/\sqrt{\pi \cdot h_l}$, $a_l = 1/\sqrt{\pi \cdot h_s}$, $h_l/(2 \cdot a_s)$, and $h_s/(2 \cdot a_l)$, are also given, for better illustration purposes.

161 together with the corresponding h_l and h_s values necessary for their computation. The larger,
 162 positive zero h_l of the equation in (17) determines a more 'elongated' fitting cylinder, while the
 163 smaller positive zero of the equation in (17) determines the cylinder that is less elongated. The
 164 values $a_s = \frac{1}{\sqrt{\pi \cdot h_l}}$ and $a_l = \frac{1}{\sqrt{\pi \cdot h_s}}$, that correspond to the values h_l and h_s , respectively, are
 165 also given. The corresponding values $\frac{h_l}{2 \cdot a_s}$ and $\frac{h_s}{2 \cdot a_l}$ are also provided, in order to illustrate
 166 how much the fitting cylinders are elongated.

167 At the moment, it seems reasonable to say that the first, second and third shape, in the first
 168 row, are better fitted with the more elongated cylinder (determined by the bigger h value (i.e. by
 169 the computed parameter h_l). The fourth shape (in the first row) does look to be far away from a
 170 cylindrical shapes. This is why is difficult to have a perception which of two computed fit cylinders
 171 would be a better fit to the shape displayed. A method to evaluate numerically how good is fitting
 172 between the shape considered and their related fitting cylinders, as well as properties of such the
 173 method, will be discussed in the following section.

174 More shapes and their corresponding fitting cylinders can be found in the Fig.3-6. This time
 175 the fitting cylinders are given by their unique parameters h_l and h_s , but they are not displayed, as
 176 it has been done in Fig.2.

177 4 Cylinderness Measure for 3D Shapes

178 In this section we observe how a comparison between the shape given and its two fitting cylinders,
 179 could lead a numerical evaluation of how much a shape given looks like a cylinder⁴ Such a computed
 180 quantity will be called the *shape cylinderness measure*.

181 As it has been shown, there are two solutions h_l and h_s of the equation in (17), and these
 182 solutions define two fitting cylinders

$$C\left(h_l, a_s = \frac{1}{\sqrt{\pi \cdot h_l}}\right) \quad \text{and} \quad C\left(h_s, a_l = \frac{1}{\sqrt{\pi \cdot h_s}}\right). \quad (28)$$

183 There are many ways how two shapes can be compared. Herein we will employ a very general one,
 184 that can applied to arbitrary pair of shapes. Such a shape comparison leads to two quantities,
 185 $\mathcal{C}_a(S)$ and $\mathcal{C}_b(S)$ (see Definition 2), and further to the new 3D shape cylinderness measure, as given
 186 in Definition 3.

187 Later on, in the next section, we will describe a modified measure that simplifies the computa-
 188 tion, still keeps nice measure properties, but slightly reduces the situations were it can be applied
 189 directly (to the highly symmetric shapes, for example).

⁴Notice that a comparison with just one of these fitting cylinders does not lead to the measure satisfying the desirable properties like those listed in the Theorem1. This is, for example, because $\mathcal{C}_a(S) = \mathcal{C}_b(S) = 1$ cannot be true for an arbitrary shape (cylinder) S . More precisely, $\mathcal{C}_a(S) = \mathcal{C}_b(S) = 1$ would imply that S coincides with both fitting cylinders corresponding to the parameters a and b . This is not possible.

190 **Definition 2** Let a 3D shape S be given. Let the volume of S be equal to 1 and the centroid of S
 191 be coincident with the origin. We define two auxiliary quantities $\mathcal{C}_a(S)$ and $\mathcal{C}_b(S)$ as follows:

$$\mathcal{C}_a(S) = \max_{S(\alpha)} \left\{ \frac{\text{Volume}(S(\alpha) \cap C(h_l, a_s))}{\text{Volume}(C(h_l, a_s))} \right\} \quad (29)$$

192

$$\mathcal{C}_b(S) = \max_{S(\alpha)} \left\{ \frac{\text{Volume}(S(\alpha) \cap C(h_s, a_l))}{\text{Volume}(C(h_s, a_l))} \right\} \quad (30)$$

193 where

194 – h_l and h_s are zeros of the equation in (17), allocated to the shape S ;

195 – $a_s = \frac{1}{\sqrt{\pi \cdot h_l}}$, $a_l = \frac{1}{\sqrt{\pi \cdot h_s}}$;

196 – $C(h_l, a_s)$ and $C(h_s, a_l)$ are cylinders defined as in (6); and finally,

197 – $S(\alpha)$ is a shape obtained by an arbitrary rotation of the shape S around its centroid.

198 Now, we are able to give a formal definition of the new cylinderness measure, denoted by $\mathbf{C}(S)$.

199 **Definition 3** Let a shape S , whose volume is equal to 1 and whose centroid coincides with the
 200 origin, be given. The 3D shape cylinderness measure, $\mathbf{C}(S)$, is defined as follows:

$$\mathbf{C}(S) = \max \{ \mathcal{C}_a(S), \mathcal{C}_b(S) \} \quad (31)$$

201 where $\mathcal{C}_a(S)$ and $\mathcal{C}_b(S)$ are as in (29) and (30), respectively.

202 The next theorem lists important properties of the measure $\mathbf{C}(S)$.

203 **Theorem 1** The cylinderness measure $\mathbf{C}(S)$ has the following properties:

204 (a) $\mathbf{C}(S) \in [0, 1]$, for all the 3D shapes S ;

205 (b) $\mathbf{C}(S) = 1 \Leftrightarrow S$ is a cylinder;

206 (c) $\mathbf{C}(S)$ is invariant with respect to the translations, rotations, and scaling transformations.

207 **Proof.** The items (a) and (c) follow from the definition. To prove (b) let us assume that S_0 is a
 208 unit volume cylinder $C(h_0, a_0)$, defined by the parameters $h = h_0$ and $a_0 = \frac{1}{\sqrt{\pi \cdot h_0}}$, as given in (6).

209 This further means

$$J(S_0) = \frac{1}{2 \cdot \pi \cdot h_0} + \frac{h_0^2}{12} \quad (32)$$

210 based on (15). Entering the equality in (32) into (17), we get

$$\pi \cdot h^3 - 12 \cdot \pi \cdot h \cdot \left(\frac{1}{2 \cdot \pi \cdot h_0} + \frac{h_0^2}{12} \right) + 6 = 0. \quad (33)$$

211 The equality in (33) is equivalent to

$$\pi \cdot (h - h_0) \cdot \left(h \cdot (h + h_0) - \frac{6}{\pi \cdot h_0} \right) = 0. \quad (34)$$

212 Thus, $h = h_0$ is the solution of the equation in (33), and the method offers the cylinder $C \left(h_0, a = \frac{1}{\sqrt{\pi \cdot h_0}} \right)$,
 213 as one of the best fitted cylinders to the given shape S_0 . Since $S_0 = C \left(h_0, a = \frac{1}{\sqrt{\pi \cdot h_0}} \right)$, this further
 214 means that either $\mathcal{C}_1(S_0) = 1$ or $\mathcal{C}_2(S_0) = 1$, is true (see (29) and (30)). So, $\mathbf{C}(S_0) = 1$ is proven,
 215 due to the equality/definition in (37).

216 On the other side, if $\mathbf{C}(S_0) = 1$ then it must be either $\mathcal{C}_a(S_0) = 1$ or $\mathcal{C}_b(S_0) = 1$. Due to the
 217 definitions in (29) and (30), the shape S_0 must coincide with one of the fitting cylinders, $C(h_l, a_s)$
 218 and $C(h_s, a_l)$, where h_l and h_s are the solutions of the equation in (17). This establishes the proof.
 219 \square

220 5 Experimental Section

221 In this section, first, we give a modified version of the cylinderness measure established in the
 222 previous section. Then, we provide several experiments in order to enable a better understanding
 223 how the modified cylinderness measure behaves. All experiments also include the unique parameters
 224 (h_l and h_s), necessary to reconstruct the fitting cylinders, related to the shapes considered. This
 225 time the cylinders are not displayed, as this has been done in Fig. 2

226 5.1 A Modified Cylinderness Measure

227 Till now, all the theoretical framework was established by working in a continuous space. However,
 228 in image processing and computer vision tasks, and more generally, in images technology based
 229 object analysis procedures, we deal with computer images - i.e. in situations where real 3D objects
 230 are presented with the sets of voxels inside the objects. Because of that, the maxima in (29) and
 231 (30) can be only computed numerically. Of course, this always causes an inherent error. Such an
 232 error is not large, in this particular case. This is because the volumes of 3D regions, as required
 233 in (29) and (30), can be approximated efficiently just by enumerating the integer points (voxels)
 234 inside the 3D region considered [4, 11].

235 A straightforward numerical computation of the maximums in (29) and (30), by using incre-
 236 mental angles rotations around the object centroid, can be time consuming, particularly if the
 237 objects considered are represented by a high 3D image resolution, i.e. if the objects consist of a
 238 large number of voxels.

239 Because of the above, we will relax conditions in Definition 2, in order to preserve a simpler
 240 computation. We propose efficient substitutes for the quantities $\mathcal{C}_a(S)$ and $\mathcal{C}_b(S)$, and the cylin-
 241 derness measure $\mathbf{C}(S)$, (see Definition 3), that can be computed without a use of any incremental

242 optimizing procedure. More precisely, the shapes considered are oriented such that their principal
 243 axes [5] coincide with the principal axes of their fitting cylinders, and all the necessary compu-
 244 tations are done without any additional incremental rotations of the shapes measured. All the
 245 theoretical observations and the statements made are analogue to those in the previous sections.
 246 The key statements still remain valid for the modified measure, as in the case of the $\mathbf{C}(S)$ measure.
 247 Thus, the proofs are omitted.

248 **Definition 4** *Let a 3D shape S be given. Let the volume of S be equal to 1 and the centroid of S*
 249 *be coincident with the origin. We define two following quantities $\mathcal{C}_1(S)$ and $\mathcal{C}_2(S)$ as follows:*

$$\mathcal{C}_1(S) = \max_{S(\beta)} \left\{ \frac{\text{Volume}(S(\beta) \cap C(h_l, a_s))}{\text{Volume}(C(h_l, a_s))} \right\} \quad (35)$$

250

$$\mathcal{C}_2(S) = \max_{S(\beta)} \left\{ \frac{\text{Volume}(S(\beta) \cap C(h_s, a_l))}{\text{Volume}(C(h_s, a_l))} \right\} \quad (36)$$

251 *where $S(\beta)$ equals the shape S oriented such that its principal axes coincide with the principal axes*
 252 *of the fitting cylinders $C(h_l, a_s)$ and $C(h_s, a_l)$ ⁵.*

253 Now, we are able to give a formal definition of the measure $\mathcal{C}(S)$ that is a modification of the
 254 $\mathbf{C}(S)$ measure.

255 **Definition 5** *Let a shape S , whose volume is equal to 1 and whose centroid coincides with the*
 256 *origin, be given. The 3D shape cylinderness measure, $\mathcal{C}(S)$, is defined as follows:*

$$\mathcal{C}(S) = \max \{ \mathcal{C}_1(S), \mathcal{C}_2(S) \} \quad (37)$$

257 *where $\mathcal{C}_1(S)$ and $\mathcal{C}_2(S)$ are as in (35) and (36), respectively.*

258 **Note 4** *The time complexity of the initial method for the computation of the cylinderness measure*
 259 *varies depending on the number of incremental rotations required (see Definition 2). It goes from*
 260 *– an asymptotically optimal time complexity of $\mathcal{O}(N)$ (N is the number of shape points) if the*
 261 *number of incremental rotations is fixed;*

262 *to*

263 *– an unbounded complexity, if the number of incremental rotation used, is unbounded too.*

264 *Thus, the dominance of the modified method, compared to the one based on Definition 2, can be*
 265 *significant if the number of incremental rotations used is big enough.*

266 The next theorem lists desirable properties of the measure $\mathcal{C}(S)$. These properties are analogue
 267 to the properties of the $\mathbf{C}(S)$ measure (see Theorem 1).

⁵We still use the maximum operator in (35) and (36), but there are no more than 8 choices for β . Just to mention that the number of α values in (29) and (30) can be selected to be arbitrary large.

268 **Theorem 2** *The cylinderness measure $\mathcal{C}(S)$ has the following properties:*

269 (a) $\mathcal{C}(S) \in [0, 1]$, for all the 3D shapes S ;

270 (b) $\mathcal{C}(S) = 1 \iff S$ is a cylinder;

271 (c) $\mathcal{C}(S)$ is invariant with respect to the translations, rotations, and scaling transformations.

272 We start our experiments with synthetic shapes. After that we use a relatively small collection
273 of shapes from the well know data set [20]. The results obtained are reasonable, and we may say,
274 fit well with human perception.

275 As it has been mentioned, in all the experiments we had to work on discretized data – i.e. on
276 the objects presented by the sets of voxels. This is why all computed values and parameters are
277 approximate ones, and given as decimal numbers.

278 5.2 Experiments on Synthetic Data

279 To illustrate the behavior of the new measure $\mathcal{C}(S)$ we have used a 3D cube stretched/shrunk for
280 different coefficients, in direction of the coordinate axes. The results are given in Fig.3. Five objects
281 are considered. The first object, in the first row, is a regular cube. It has relatively high cylinderness
282 measure ($\mathcal{C}(S) = 0.8458$). It is worth noticing that the corresponding values $\mathcal{C}_1(S) = 0.8458$ and
283 $\mathcal{C}_2(S) = 0.7875$ are relatively close. This can be explained by a relatively high N -fold symmetry
284 of a regular cube. The next two shapes, whose edge-length ratio differs essentially (i.e. these are
285 $1 \times 1 \times 2$ and $1 \times 1 \times 8$) have almost the same computed cylinderness measure, 0.9093 and 0.9091,
286 respectively This is not a surprise taking into account that both measured 3D shapes have a square
287 as the base, instead of the circle. This is the only difference from a perfect cylinder.

288 Anyhow, once the shape S varies, its allocated fitting cylinders vary, as well (even though the
289 corresponded cylinderness measure may stay the same). Indeed, for the second and third shape,
290 in Fig.3 these cylinders are determined by the parameters, that differs very much, $h_l = 1.5846$
291 and $h_s = 0.5616$ (for the second shape), and $h_l = 3.8909$ and $h_s = 0.1223$ (for the third shape).
292 However, the comparison of the second shape with allocated fitting cylinder $C(h_l = 1.5846)$ and
293 comparison of the third shape with the allocated fitting cylinder $C(h_l = 3.8909)$ leads to almost
294 identical cylinderness measures (0.9093 and 0.9091 respectively). It might be worth noticing that
295 their comparison with the corresponding fitting cylinders $C(h_s = 0.5626)$ and $C(h_s = 0.1223)$ leads
296 to the essentially different scores of $\mathcal{C}_2(S) = 0.6562$ and $\mathcal{C}_2(S) = 0.1967$, respectively.

297 Regarding the fourth and fifth shape in the first row in Fig.3, we notice that the computed
298 cylinderness measures are obtained by comparing these shapes with the cylinders $C(h_s = 0.3871)$
299 and $C(h_s = 0.2466)$. In other words, the method says that these shapes are more similar to the less

				
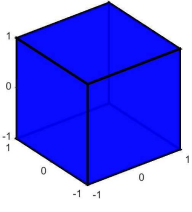

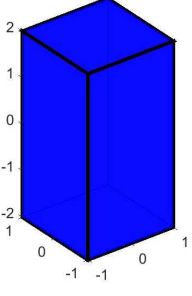

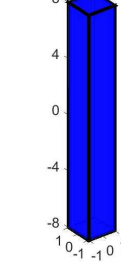

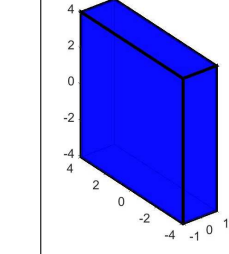

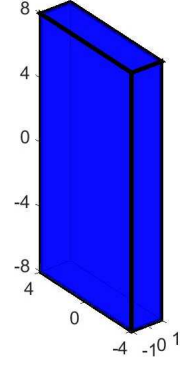

$1 \times 1 \times 1$	$1 \times 1 \times 2$	$1 \times 1 \times 8$	$1 \times 4 \times 4$	$1 \times 4 \times 8$
$h_l = 1.1613$ $\frac{h_l}{2 \cdot a_s} = 1.1091$ $\mathcal{C}_1(S) = 0.8458$	$h_l = 1.5846$ $\frac{h_l}{2 \cdot a_s} = 1.7678$ $\mathcal{C}_1(S) = 0.9093$	$h_l = 3.8909$ $\frac{h_l}{2 \cdot a_s} = 6.8017$ $\mathcal{C}_1(S) = 0.9091$	$h_l = 2.0359$ $\frac{h_l}{2 \cdot a_s} = 2.5744$ $\mathcal{C}_1(S) = 0.4826$	$h_l = 2.6625$ $\frac{h_l}{2 \cdot a_s} = 3.8502$ $\mathcal{C}_1(S) = 0.5344$
$h_s = 0.8271$ $\frac{h_s}{2 \cdot a_l} = 0.6666$ $\mathcal{C}_2(S) = 0.7875$	$h_s = 0.5616$ $\frac{h_s}{2 \cdot a_l} = 0.3730$ $\mathcal{C}_2(S) = 0.6562$	$h_s = 0.1223$ $\frac{h_s}{2 \cdot a_l} = 0.0379$ $\mathcal{C}_2(S) = 0.1967$	$h_s = 0.3871$ $\frac{h_s}{2 \cdot a_l} = 0.2134$ $\mathcal{C}_2(S) = 0.8391$	$h_s = 0.2466$ $\frac{h_s}{2 \cdot a_l} = 0.1085$ $\mathcal{C}_2(S) = 0.7024$
$\mathcal{C}(S) = 0.8458$	$\mathcal{C}(S) = 0.9093$	$\mathcal{C}(S) = 0.9091$	$\mathcal{C}(S) = 0.8391$	$\mathcal{C}(S) = 0.7024$

Figure 3: Five shapes obtained by stretching a cube, for different coefficients, are in the first row. The edge-length ratios are immediately below the shapes obtained. The parameters of the corresponding fitting cylinders are also given, as well as the computed quantities $\mathcal{C}_1(S)$ and $\mathcal{C}_2(S)$, for each of the shapes considered. The computed cylinderness measure values are in the last row.

				
teddy10	dolphins3	four29	octopuses4	pliers2
$h_l = 2.0936$ $\frac{h_l}{2 \cdot a_s} = 2.6846$ $\mathcal{C}_1(S) = 0.7447$	$h_l = 2.5487$ $\frac{h_l}{2 \cdot a_s} = 3.6060$ $\mathcal{C}_1(S) = 0.7770$	$h_l = 3.0153$ $\frac{h_l}{2 \cdot a_s} = 4.6402$ $\mathcal{C}_1(S) = 0.5447$	$h_l = 2.9769$ $\frac{h_l}{2 \cdot a_s} = 4.5519$ $\mathcal{C}_1(S) = 0.2689$	$h_l = 4.1306$ $\frac{h_l}{2 \cdot a_s} = 7.43994$ $\mathcal{C}_1(S) = 0.2034$
$h_s = 0.3702$ $\frac{h_s}{2 \cdot a_l} = 0.1996$ $\mathcal{C}_2(S) = 0.5669$	$h_s = 0.2848$ $\frac{h_s}{2 \cdot a_l} = 0.1217$ $\mathcal{C}_2(S) = 0.4343$	$h_s = 0.1972$ $\frac{h_s}{2 \cdot a_l} = 0.0776$ $\mathcal{C}_2(S) = 0.3029$	$h_s = 0.2018$ $\frac{h_s}{2 \cdot a_l} = 0.0803$ $\mathcal{C}_2(S) = 0.1595$	$h_s = 0.1091$ $\frac{h_s}{2 \cdot a_l} = 0.0319$ $\mathcal{C}_2(S) = 0.2326$
$\mathcal{C}(S) = 0.7447$	$\mathcal{C}(S) = 0.7770$	$\mathcal{C}(S) = 0.5447$	$\mathcal{C}(S) = 0.2689$	$\mathcal{C}(S) = 0.2326$

Figure 4: Five shapes from different classes in [20] are in the first row. The related parameters (h_l , $h_l/(2 \cdot a_s)$, $\mathcal{C}_1(S)$, h_s , $h_s/(2 \cdot a_l)$, and $\mathcal{C}_2(S)$) are displayed below the corresponding shapes. The cylinderness measures $\mathcal{C}(S)$ computed are in the last row.

300 elongated cylinders (in the sense of the $h_s/(2 \cdot a_s)$ and $h_s/(2 \cdot a_l)$ ratios) than to the (more elongated)
301 cylinders determined by larger h_l values (i.e. the cylinders $\mathcal{C}(h_l = 2.0359)$ and $\mathcal{C}(h_l = 2.6625)$).

302 This might be understood as expected and intuitively clear outcome and confirmation that both
303 fitting cylinders have to be taken into account if we would like to compute the cylinderness measure
304 of of the shapes considered.

305 5.3 Experiments on a Known 3D Shapes Data-set Examples

306 In this subsections we have used shapes from the well-known data-set [20].

307 – Five shapes, in Fig.4, are selected randomly from different shape classes, and their cylinderness
308 measures are computed. The related parameters h_l and h_s , of the corresponding fitting cylinders,
309 the visualizations supporting ratios $h_l/(2 \cdot a_s)$ and $h_s/(2 \cdot a_l)$, and related quantities $\mathcal{C}_1(S)$ and $\mathcal{C}_2(S)$
310 are also provided.

311 The obtained results might be understood as expected ones. The highest cylinderness measure
312 is computed for the first two shapes. The third shape is ‘bended’ slightly, which has caused a

					
humans15	humans17	hands3	hands2	snakes14	snakes25

$\mathcal{C} = 0.6723$	$\mathcal{C} = 0.4794$	$\mathcal{C} = 0.6396$	$\mathcal{C} = 0.6606$	$\mathcal{C} = 0.0667$	$\mathcal{C} = 0.4122$

Figure 5: Three pairs of shapes, from the data set [20], are used to illustrate the $\mathcal{C}(S)$ behavior under the shape deformation transformations. Immediately below the shapes are their names as given in [20]. The related shape parameters and the quantities $\mathcal{C}_1(S)$ and $\mathcal{C}_2(S)$ are also provided. The measured shape cylinderness values are in the last row.

313 decrease in the cylinderness measure computed. The lowest cylinderness measure is computed
314 the pliers shape (the shape on the right). This is also in accordance with our perception. It might
315 be worth mentioning that the cylinderness measure for this pliers shape comes from the shape
316 comparison with the cylinder determined by the smaller computed h (i.e. h_s) value. The rest of
317 the shapes, in Fig.4 fit better with the cylinder determined by the higher h (i.e. h_l) value, computed
318 from the equation in (17).

319 – The behavior of the new cylinderness measure $\mathcal{C}(S)$ under the shape deformation transfor-
320 mations is illustrated by examples in Fig.5. Three pairs of shapes, from different classes in [20],
321 are considered. The second shape in each pair of shapes presented can be understood as the first
322 shape (in the related pair) subjected to certain level of a deformation transform. Depending on
323 the level of deformation applied, the computed $\mathcal{C}(S)$ values vary differently. The largest difference
324 is computed for two 'snake' shapes (the last two shapes in the first row). The same could be said
325 for the related quantities $\mathcal{C}_1(S)$ and $\mathcal{C}_2(S)$ inside of each pair.

5.4 Robustness under Erosion Transformation

In the next experiments we consider the robustness of the new measure, under erosion transformations. We have used a cylinder whose height is $h = 20.02$ the base radius is $a = 4.2$. As it has been mentioned, herein we have to work with the discretized real objects. So, the cylinder observed is represented by using the cubes/voxels of the size $1 \times 1 \times 1$. In this particular case, the number of voxels, whose centers belong to the cylinder observed, was 1092. The discretized/voxelized cylinder is displayed on the left, in Fig.6. The voxel centers, in the shapes in Fig.6, are represented by the dots. For such obtained voxelized data, the shape of the original cylinder shape is estimated to be equal to the shape of a unit volume cylinder $C(h = 2.0361)$ (i.e. with the parameter $h_l = 2.0361$). It has turned out, the estimated cylinderness measure was equal to 1. In other words, it has happened that all the scaled voxels, belonging to the normalized observed cylinder, were inside the fitting cylinder $C(h_l = 2.0361)$, as well. It is worth mentioning that for another choice of digitized cylinder (whose parameters differ from $h = 20.02$ and $a = 4.2$), the estimated cylinderness may vary.

Next, we have removed a certain number of voxels from the original cylinder (i.e. its discretization). These voxels are selected randomly. For the second, third, and fourth shape, in the first row in Fig.6, the number of voxels removed were nearly 10%, 20%, and 40%, respectively. The exact number of voxels, remaining to represent the initial shape, is given immediately below the shapes related. Roughly speaking, the computed cylinderness measure $\mathcal{C}(S)$, of such eroded shape, has been changed (decreased) accordingly to the percentage of the voxels removed. It is up to the readers to judge if the presented robustness is good enough for their possible applications.

We also have provided the data (i.e. h_l and h_s values) showing how do fitting cylinders (allocated the shapes eroded) change under such erosion transformations applied. Again, we leave the judgment of the quality of the results obtained to the readers. Surely, the judgment would depend on the application planned to be done.

Comments similar to the comments above apply to the first shape in the second row, even though the erosion level is very high (more than 50% voxels were removed). The last two shapes, in the second row, are given to illustrate that the cylinderness measure $\mathcal{C}(S)$ can be applied to an arbitrary set of 3D points (or voxels), not necessary to the point-sets that do suggest that they represent connected 3D objects, or 3D objects of a specific class (in this case the digitized 3D cylinders). Thus, very small $\mathcal{C}(S)$ values, for the last two shapes, are not surprising.

6 Concluding Remarks

A theoretical framework has been established to solve a cylinder fitting problem for 3D shapes. It has been turned out that the method established allocates two fitting cylinders for any of 3D shapes,

			
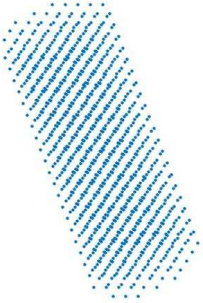

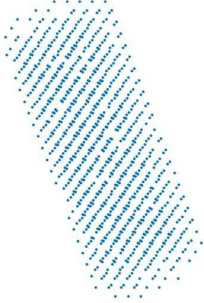

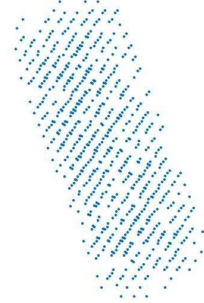

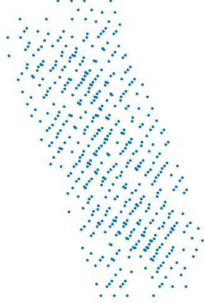

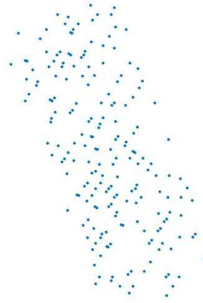

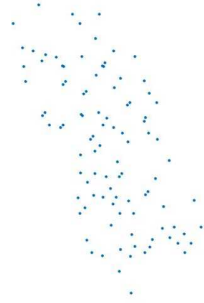

1092 voxels	1000 voxels	900 voxels	700 voxels
$h_l = 2.0361 \mathcal{C}_1 = 1$	$h_l = 2.1096 \mathcal{C}_1 = 0.9260$	$h_l = 2.2153 \mathcal{C}_1 = 0.7922$	$h_l = 2.4396 \mathcal{C}_1 = 0.6257$
$h_s = 0.3871 \mathcal{C}_2 = 0.5522$	$h_s = 0.3657 \mathcal{C}_2 = 0.5050$	$h_s = 0.3377 \mathcal{C}_2 = 0.3029$	$h_s = 0.2871 \mathcal{C}_2 = 0.3629$

Figure 6: The discrete point set in the first row on the left represents a cylinder discretized on a regular $3D$ integer grid. The rest of the shapes are obtained by removing a certain number of points from the shape on the left. The number of the points removed is immediately below the shapes. The rest of voxels were used to approximate cylinderness measure \mathcal{C} of such discrete point sets, consisting of unit volume voxels/cubes. The values, given below the shapes, relate to the estimated fitting cylinders (h_l and h_s), the computed quantities \mathcal{C}_1 and \mathcal{C}_2 , and finally to the computed cylinderness measures \mathcal{C} .

360 with small exception for nearly spherical 3D shapes. If the method is applied to the 3D voxelized
361 shapes it has an asymptotically optimal time complexity – i.e. it has the $\mathcal{O}(N)$ computational
362 complexity, where N is the number of voxels that belong to the digitized shape considered.

363 Further, the fitting cylinders obtained are used to design a new 3D shapes measure. This
364 measure is named a *cylinderness measure*, since it gives a numerical evaluation of how much a 3D
365 shape given looks like a perfect cylinder. The new measure has the following desirable properties:
366 **(i)** It varies through the interval $[0, 1]$; **(ii)** The measure picks the value 1 if and only if the shape
367 measured is a cylinder; **(iii)** The measure is invariant with respect to the translation, rotation, and
368 scaling transformations. Being theoretically well founded, the behavior of the new measure can be
369 predicted to some extent, without verification experiments needed. This is always an advantage.

370 The initial method (described in Definition 2 and Definition 3) requires the incremental rotations
371 of the shape measured (see the role of the parameter α in Definition 2), for the computation of the
372 cylinderness measure. In order to avoid the required incremental rotations of the shape considered, a
373 modified method for the computation of the shape cylinders measure is introduced (see Definition
374 4 and Definition 5). The modified method uses principal axes, for the 3D shape cylinderness
375 computation. In this way incremental rotations are not needed. The fitting cylinders are the same
376 in initial method and its modification.

377 Notice that the computation of fitting cylinders, for a given shape S , is a *shape based* one since it
378 is based on the (shape moments) invariant $J(S)$. The invariant $J(S)$ is computable from low-order
379 moments, i.e. the moments whose order is upper bounded by two. Such a selection is made to
380 simplify the computation of the fitting cylinder parameters. The cylinderness measure established
381 uses a standard geometric approach, where the set difference between the shape considered and its
382 fitting cylinders is observed.

383 Several experiments on synthetic data/shapes and the shapes selected from the well-known
384 McGill 3D Shape Benchmark data set [20] are provided. The cylinders measure values obtained
385 may be understood as reasonable and expected ones.

386 Experiments on shapes subjected to deformation transforms, and eroded discretized shapes are
387 also provided. These show that the new measure is robust.

388 Despite the fact that all theoretical derivations and observations are made in a continuous
389 space, the new cylinderness measure is aimed to be applied to the computer manipulated 3D
390 images, or more generally 3D point sets. Thus, all the experiments are performed on discrete point
391 sets, obtained in a process of the voxelization of real objects. This always implies an inherent
392 computation error. A good thing here is that the measure is applied to the solid 3D shapes
393 – i.e. all the shape points are taken into account, not only the boundary ones, for example.
394 This further implies that all the parameters (the 3D moment invariant used, and volumes of the
395 shapes considered), needed for the computation of the cylinderness measure $\mathcal{C}(S)$, can be computed

396 efficiently (within a small approximation error), as it is well known [4, 11] from the number theory.

397 **7 Acknowledgment**

398 The authors wish to thank to Dr. Carlos Martinez-Ortiz for his help during the preparation of this
399 paper.
