Attenuated effector T cells are linked to control of chronic HBV infection

In the format provided by the
authors and unedited

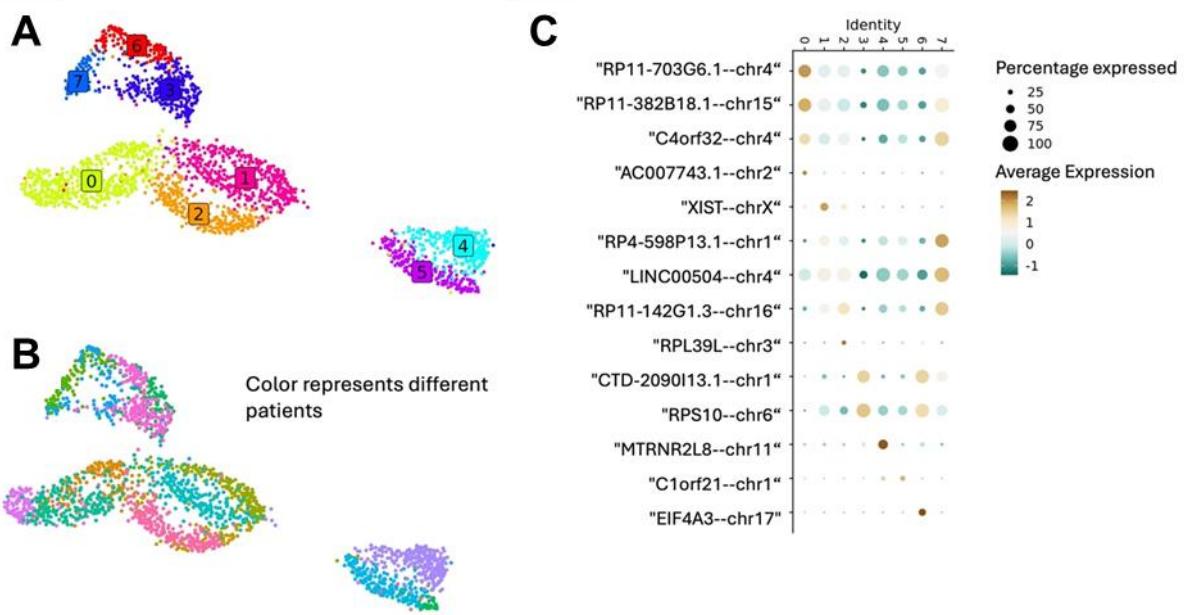

Supplementary figure 1:

Percentage of ribosomal and mitochondrial genes in (A) HBV core₁₈-specific and HBV pol₄₅₅-specific CD8+ T cells of endogenous control/chronic HBV and NUC control/chronic HBV and in (B) HBV pol₄₅₅-specific CD8+ T cells of endogenous control/chronic HBV, acute and acute resolved HBV infection are depicted.

Supplementary figure 2:

Violin Plots showing the number of genes and transcripts per cell of cells with $> 1.5\%$ KCNQ1OT1 transcripts and cells with $< 1.5\%$ KCNQ1OT1 transcripts which were included in the analysis. Note that the numbers of genes and transcripts per cell are significantly lower in cells with $> 1.5\%$ KCNQ1OT1 transcripts indicating that these are low quality cells.

Supplementary figure 3:

UMAP representation showing **(A)** clusters and **(B)** patients of HBV-specific T cells without batch correction in different colors. Note that without batch correction, clustering is primarily governed by patients. **(C)** Differential gene expression analysis of this clustering further reveals many non-long coding RNAs and ribosomal proteins differentially expressed among patients and dominated the differential gene expression analysis. Few examples are shown in the Dot plot.

Supplementary Table 1: Study cohort of HLA-A*02:01 positive individuals with endogenous control (HBeAg- cHBV infection)
