Abstract

We study how job-related well-being (measured by Warr's 'Enthusiasm' and 'Contentment' scales) altered through the Great Recession, and how this is related to changing job quality. Using nationally representative data for Britain, we find that job-related well-being was stable between 2001 and 2006, but then declined between 2006 and 2012. We report relevant changes in job quality. In modelling the determinants of job-related well-being, we confirm several previously-studied hypotheses and present some new findings: downsizing, work re-organisation, decreased choice, and linking pay to organisational performance each reduce well-being; indicators of skills challenge in jobs have more of a positive association with Enthusiasm than with Contentment, while effort has a more negative association with Contentment than with Enthusiasm. Our estimates are largely orthogonal to the effects of personality traits and demographic controls on well-being. Using a standard decomposition, we find that the 2006-2012 fall in job-related well-being is partly accounted for by accelerations in the pace of workplace change, rising job insecurity, increased effort and changing participation.

Job-Related Well-Being Through the Great Recession

Introduction

This paper is concerned with what happens to the job-related well-being of those in employment in a major recession. Periods of economic crisis and stagnation are typically seen as occasions for accelerated changes in employment and production relations. Whether through Schumpeterian creative destruction or through a shift in the balance of power, the opportunity may be taken to renew working methods, relationships and pay bargains, with consequences for both employers and their employees. Major economic downturns are known to generate falls in general well-being (as manifested in overall life satisfaction and health indicators) which extend beyond those rendered involuntarily unemployed to the broader workforce who feel less secure and to their dependants (Burchell 1994; Di Tella et al. 2003; Green 2011). The focus here, however, is on how indicators of *job-related* well-being (feelings about one's job) are changed over a recession, and on how this is related to changing job quality. To investigate this, we examine the specific instance of employees in Britain before and after the 'Great Recession' of 2008-9.

Since job-related well-being is an end in itself, studying it needs no additional motivation. Nevertheless, there is evidence that job-related well-being is associated with productivity, absenteeism and labour turnover (e.g. Böckerman and Ilmakunnas 2012; De Neve et al. 2013; Warr 2007; Zelenski et al. 2008) – even if much remains to be done to determine the magnitude of the causal effects. In recent years well-being -- including in the domain of work -- has been assigned a place in the 'beyond GDP' agenda (Stiglitz et al. 2009). A better understanding of various dimensions of well-being at an aggregate level are relevant to this agenda, and should also prove helpful in the analysis of labour markets. Britain's experience of the Great Recession was fairly typical among many other countries, with falling GDP and rising unemployment. Between 2008(Q1) and 2009(Q3) the fall in GDP (6.03%) was somewhat larger than the average among OECD countries (4.15%) (OECD 2010). The fall in employment over the same period being (at 1.92%) a little lower than for the OECD as a whole (2.30%), Britain's aggregate

1
2
3
4 productivity fell more than the average. Nevertheless, it is plausible to suppose that the
5 findings for Britain might generalise to many other developed countries.
6
7

8
9 This paper contributes in four ways. First, we show what has been happening to the economy-
10 wide average level of job-related well-being in Britain. Since 2001 we have collected three
11 cross-sections of large-scale nationally-representative data, with which we can document the
12 trend in two dimensions of job-related well-being, using indicators devised by Warr (1990a;
13 2007). Our second contribution is to decompose the differences in job-related well-being over
14 time, showing the proportions of these differences that can be modelled or 'explained' by
15 variation in observed measures of job quality, and how much is left unexplained. Our third new
16 contribution arises through this modelling of job-related well-being. Economics, psychology and
17 sociology all provide theory as to how job characteristics are expected to be related to well-
18 being. We fit models derived from core theories, concerning the effects of effort (work intensity
19 and duration), participation, skills challenge and insecurity. In so doing we provide tests of
20 hypotheses concerning the non-linearity of effort's effect on well-being, the effects of
21 performance-related pay, the effects of workplace change, and some variations in effects
22 between different dimensions of well-being. Finally, this modelling also incorporates several
23 better-established findings in the literature on the study of work. Most of these findings have
24 been established in relatively small-scale, focussed, studies of particular work settings or
25 occupations. Our fourth contribution is to examine whether these findings can be confirmed in
26 the context of a nationally-representative survey, covering a wide variety of workers and jobs.

44 The paper proceeds, first, by clarifying the concept of job-related well-being, outlining the core
45 theories to be incorporated into our model, and noting the existing evidence. The following
46 section describes our data and all the relevant indicators, and this leads into our presentation
47 of a picture of changing well-being and of changing job quality in Britain, comparing before and
48 after the onset of the Great Recession. Model findings are then presented, culminating in the
49 decomposition analysis.

59 **Theory and prior evidence linking job characteristics and job-related well-being**

1
2
3
4 Psychological research has suggested that there are two substantive, if not exhaustive,
5 orthogonal dimensions to the structure of feelings, namely 'arousal' and 'pleasure' (Warr
6 1990a; 2007). Within the 'arousal'/'pleasure' plane there are two correlated dimensions,
7 namely Depression-Enthusiasm and Anxiety-Contentment. This structure for subjective well-
8 being has the advantage that it can apply to feelings arising from both work and non-work
9 settings. In this paper we use a shortened nomenclature, namely 'Enthusiasm' and
10 'Contentment'. Enthusiasm is positively correlated with the arousal and pleasure axes.
11 Contentment, by contrast, is correlated positively with the 'pleasure' dimension and negatively
12 with the 'arousal' dimension. Applied to the job, employees with high Enthusiasm – with high
13 pleasure and stimulation from their work -- are said to have feelings central to the model of
14 "thriving" (Spreitzer et al. 2005), while conversely those with low Enthusiasm express feelings
15 of depression, who take no pleasure from their work and are passive. Those with high
16 Contentment find their jobs acceptable but are said to have a "resigned satisfaction", while
17 conversely those with low Contentment express feelings of anxiety, being both aroused by and
18 experiencing displeasure from their work (Grebner et al. 2005; Warr 2007: 22). These two
19 dimensions have been found to affect behaviour, including quitting and absenteeism (Green
20 2010; Warr 2007: 427-434). As Warr notes (2007: 19-60), both dimensions are positively related
21 to mental health indicators (but in subtle ways involving varying thought processes) and to
22 other constructs such as organisational commitment and job satisfaction.

39
40
41 Warr (1990a) has examined and validated instruments (to be described below) that tap these
42 dimensions. Other concepts of job-related well-being are also sometimes available for analysis.
43 Not least, job satisfaction might be considered as an indicator of well-being along the 'pleasure'
44 dimension, even though its interpretation depends a great deal on workers' expectations of
45 potential alternative work settings (Brown et al. 2012). In recent years other researchers have
46 developed subjective well-being scales which incorporate cognitive evaluative dimensions
47 alongside affective-emotional aspects (for example, Tennant et al. 2007). We chose Warr's
48 scales of Enthusiasm and Contentment when planning the 2001 Skills Survey, given that these
49 were available in the public domain, and had been well validated and already widely cited at

4 the time (Mullarkey et al. 1999). Continuity then became essential for the identification of
5 changes over time in successive, nationally representative, samples.
6
7

8
9 We draw on core literatures to formulate hypotheses about the links between job quality and
10 subjective well-being. One can think of the determination of each dimension (*i*) of job-related
11 well-being JWB_i as:
12
13

$$14 \quad JWB_i = f_i(JQ_j, X_k)$$

15
16 In this equation JQ_j is a vector of job quality, defined as in the literature as that subset of job
17 characteristics which meet people's needs from work (Green 2006; Kalleberg 2011; Körner et al
18 2011). X_k is a vector of personal and environmental characteristics which might directly affect
19 subjective well-being or moderate the relationship between job quality and the expression of
20 subjective well-being. The psychology, sociology and economics literatures point to several sets
21 of determinants as important determinants of well-being, which may have been significantly
22 changed through the recession: effort, participation, skills challenge, insecurity and workplace
23 change.¹ A major recession directly affects insecurity and the pace of workplace change;
24 through the pressures of heightened competition, rising unemployment and the shifting
25 balance of power in the employer-worker bargain, recession may also affect worker effort and
26 moderate the long-term evolutions of skills utilisation and forms of participation (Green, 2007;
27 van Wanrooy, 2013). We discuss each of these sets of determinants in turn below. This simple
28 framework enables us to model the findings of previous studies, and to highlight some
29 hypotheses not previously tested with nationally representative data. Considering these
30 hypotheses together helps frame our expectation about how recession may have affected job-
31 related well-being.

Effort

Effort is comprised of both work intensity and work duration. Sometimes work intensity is termed as "intensive work effort", and duration as "extensive work effort" (Green 2001; 2006). The former is complex, entailing a mix of physical, mental and emotional demands at work, and involves added measurement issues due to its lack of a standard metric.²

Economics has evolved the view that intensive and extensive work effort are each a disutility at the margin, a 'bad', something that has to be experienced in order to earn a wage (Spencer 2009), and in this it parallels modern psychology (Warr 2007; Wichert 2002). Both economics (with its fundamental assumption of increasing marginal disutility of work) and psychology take the theoretical relationship of effort with well-being to be non-linear, with increasing negative marginal effects. These propositions underpin labour supply theory in economics, and as such are indirectly attested by the voluminous empirical literature on labour supply (e.g. Ashenfelter et al. 2010; Hamermesh 1993). Direct psychological studies using measures of work intensity have varied findings: some report that high effort is associated with lower levels of job satisfaction and/or Contentment, while others find a very low correlation between job satisfaction and work intensity (Warr 2007: 165-170; Wood and de Menezes 2011). Cottini and Lucifora (2013) report that higher work intensity is a source of increased mental health problems. Since the stimulation of work affects the arousal dimension, it is also expected that work intensity's effect on Enthusiasm is less negative than its effect on Contentment (Warr 1990b). However, we are not aware of any direct evidence in favour or against this expectation. These hypotheses surrounding work effort may be summarised as:

- H1: effort has an overall negative association with well-being.
- H2: the magnitude of the marginal negative effect is greater at higher effort levels
- H3: the marginal effect of work intensity on well-being is less negative in respect of Enthusiasm than in respect of Contentment.

² In the psychological literature the phrase "job demands" is, in some cases, used to mean work intensity in the sense of this paper (e.g. Hakanen et al., 2008), but more commonly job demands is used more broadly to embrace both work intensity and role conflict (Warr, 2007), even though six out of the seven items used to measure job demands by Karasek (1979) focus on work intensity.

1
2
3
4
5
6
7
8
9 *Participation*

10
11 In several complementary literatures from psychology, management, sociology and economics,
12 participation is assumed to have usually beneficial effects on job-related well-being (e.g.
13 Böckerman et al. 2012; Kalleberg et al. 2009; Karasek 1979). Yet participation is a broad concept
14 and it is useful to distinguish between two types -- decision-making participation (at various
15 levels) and financial participation in outcomes – and also between levels of participation (that
16 is, individual, work team and wider organisation). ‘Task discretion’ (over various aspects of the
17 tasks to be performed) refers to decision-making participation at the level of workers' own jobs.
18 From the economic perspective, the task discretion afforded to individual workers will depend
19 on workers' preferences (organisational commitment) and the monitoring structure (Green
20 2008), while from the sociological perspective workers' preferences are also determined by the
21 level of trust (Fox 1980). There is much evidence that task discretion enhances well-being (e.g.
22 Cottini and Lucifora 2013). There is also evidence that well-being is enhanced where the teams
23 through which work is organised are granted some influence over tasks, choice of team
24 members and team leader (Böckerman et al. 2012; Gallie et al. 2012). According to the
25 'demand-control' model, the impact of task discretion on well-being is greater where work
26 intensity is high, because higher task discretion allows workers to partially counter the stressful
27 effects of high-intensity work (Karasek 1979; Karasek and Theorell 1990). From the
28 management theorists' perspective, task discretion is just one element in the model of ‘high
29 involvement management (HIM)’ which is advanced as delivering higher organisational
30 effectiveness (Wood and de Menezes 2011). Another element in the HIM model, also stressed
31 within the sociological literature, is participation in decision-making about the organisation.
32 Indicators typically cover both upward and downward information flows, including suggestion
33 schemes, consultative meetings and the use of quality circles. Involvement through
34 representative consultation, through recognised trade unions, is also included here. These
35 types of organisational involvement are also found to be beneficial for well-being. However, the

1
2
3
4 size of the effect has been found to be less than for task discretion (Gallie 2013), and the recent
5 evidence for an interaction between organisational involvement and work effort on health is
6 equivocal (Eller et al. 2009).
7
8
9

10 These effects apply to both dimensions of well-being, with no expectation of having stronger
11 effects for one or other. Thus we have further hypotheses:
12
13

- 14 • H4: Decision-making participation in terms of task discretion is positively related to well-
15 being.
16
- 17 • H5: The effect of decision-making participation in terms of task discretion on well-being
18 is greater at high levels of work intensity.
19
- 20 • H6: Well-being is also enhanced by organisational participation
21
22
23
24

25 The anticipated effects of financial participation on well-being are, by contrast, ambivalent.
26 Financial participation refers to the presence of economic incentives through schemes that link
27 rewards with performance. On one hand, the uncertainty of performance outcomes introduces
28 an element of risk which, except for risk lovers, could be expected to lower well-being (similar
29 to the stressor effects of job insecurity, discussed below). The uncertainty may be greater for
30 pay linked to organisational rather than individual performance. Yet it is also hypothesised that
31 individual piece rates may induce overworking in some jobs and hence greater physical risk-
32 taking (Bender et al. 2012; Roy 1952). There is some evidence suggesting that performance pay
33 raises injury rates (e.g. Bender et al. 2012; Saha et al. 2004) while Freeman and Kleiner (2005)
34 find a positive association with compensation costs. Performance pay is also found to have
35 negative effects on general health (Bender and Theodossiou 2013; Foster and Rosenweig 1994).
36 On the other hand, performance pay might attract workers with a preference for risk and
37 reward. Wood and de Menezes (2011) also hypothesised that offering collective financial
38 participation might stimulate commitment, increasing the value that workers attach to being
39 part of the organisation; in the event, however, they found no significant impact from either
40 individual or group performance-related pay on Contentment. Similarly, employee discounted
41 share-purchase plans have been interpreted within the framework of a gift exchange of effort
42 for reward (Bryson and Freeman 2010). The association of financial participation with both

4 well-being domains depends on which if either of these opposing effects predominates. These
5 arguments may be posed as competing hypotheses:
6
7

- 8 • H7: financial participation is positively related to well-being.
 - 9 • H8: financial participation is negatively related to well-being.
- 10
11
12
13
14

15 *Skills challenge*

16
17 By the umbrella concept "skills challenge" we refer here to the extent to which the work itself
18 challenges employees to use their skills. The idea that a good degree of challenge can make
19 people happier has a long lineage. A substantial amount of psychological evidence establishes
20 that work which better enables people to use their abilities is associated with greater well-
21 being (e.g. Kornhauser 1965; O'Brien 1980). In a similar vein, labour economists have reported
22 a significant negative association between either overeducation or skill underutilisation and job
23 satisfaction (e.g. Allen and van der Velden 2001; Green and Zhu 2010). Because of the putative
24 link between skill use and the emotion of arousal as well as pleasure, Warr (2007) proposes in
25 addition the hypothesis that opportunity for skill use is more strongly associated with
26 Enthusiasm than with Contentment, though we are aware of no evidence in favour or against
27 this proposition. A related aspect of the skill challenge is the variety encountered in a job and
28 the need to learn new things, both of which would be expected to have the same differential
29 effects on well-being. Finally, the extent to which jobs involve carrying out repetitive tasks
30 might be expected to have negative effects on Enthusiasm, but less of a detrimental effect on
31 Contentment. All these ideas may be summed up in the hypotheses:
32
33
34
35

55

56 *Insecurity*

57
58
59
60
61
62
63
64
65

1
2
3
4 The fourth set of theories we incorporate concern insecurity, which is seen as a stressor with
5 detrimental effects on well-being, stemming from the associated loss of control (Greenhalgh
6 and Rosenblatt 1984). The impact of insecurity has also been interpreted as contributing to a
7 repudiation of the implicit 'psychological contract' (Mauno et al. 2005) or as part of a shift in
8 power relations (Scott 2004). Our primary focus is on the risk of job loss, which is expected to
9 affect both Enthusiasm and Contentment. For this there is already robust and voluminous
10 evidence from studies of ex-ante job insecurity (e.g. Burchell 1994; Cheng and Chan 2008;
11 Green 2011; Nolan et al. 2000; Wichert 2002) and indirectly from studies of ex-post indicators
12 such as job loss and unemployment (e.g. Di Tella et al. 2003; Theodossiou 1998). Insecurity can
13 also entail uncertainty over valued job features within the current job, including fears of unfair
14 treatment or loss of job status, though for lack of data in successive waves of our data series we
15 are unable to test whether such fears may add to an explanation for changing well-being (Gallie
16 et al. 2013). The main hypothesis is therefore:

- H11: Job insecurity is negatively related to well-being.

Workplace change

37 Workplace change may have an indirect effect on well-being, through its effects on any of the
38 above aspects of job quality. Yet change may also have a direct effect.

41 A direct negative impact on well-being is to be expected from the disruptions of restructuring --
42 employment downsizing, pay cuts, new technologies and work re-organisation. For example, it
43 is held that, for those employees who 'survive' it without losing their jobs, downsizing is a
44 rupture in the 'psychological contract' which reduces their organisational commitment and
45 well-being. There are a few studies to support this. Bryson et al. (2013), for example, report
46 that changes in work organisation are associated with lower Contentment, but that this effect is
47 ameliorated where unions with bargaining rights are consulted over the reorganisation. Datta
48 et al. (2010) review evidence that downsizing tends to lower job satisfaction and organisational
49 commitment. Typically, studies report greater negative direct effects on survivors of downsizing

1
2
3
4 the nearer they are to being involved, and the less fair are the perceived processes (Pepper et
5 al. 2003). A counter-argument sometimes posed, however, is that if job-related well-being is
6 assessed relative to those made redundant, there could be a positive survivor effect among
7 those in work during a recession – a feeling of relief that their jobs have not been lost. There
8 may also be direct effects (positive or negative) on well-being from changing jobs.
9

- 14 • H12: Disruptive workplace changes are negatively associated with well-being,
15 conditional on their indirect effects via changing job characteristics.
16
- 17 • H13: Surviving downsizing could be associated with relative relief, hence greater well-
18 being.
19
20
21
22
23
24

25 *The Expected Effect of Recession*

26
27 These hypotheses enable us to frame an expectation about the impact of economic downturns
28 on job-related well-being. While it is well-established that downturns are detrimental for
29 general well-being, we are concerned here with the effect on job-related well-being.
30 Recessions, which are expected to be a time of accelerated restructuring and workplace
31 change, could affect the job-related well-being of those remaining in work. In part, recessions'
32 expected effects hinge on H12 and H13. In addition, however, other job characteristics are
33 likely to alter during recessions. Overall, the potential effects are also uncertain. On one hand,
34 in a recession employers' bargaining power is increased, thus enabling them to enforce a
35 greater level of work intensity; recession and stagnation could also be expected to elevate both
36 the fear of both job loss and anxiety about unfair treatment (Gallie et al. 2013). On the other
37 hand labour hoarding in recessions implies lower work intensity and hours. There could also be
38 a selection effect, with surviving workers more likely to have higher productivity than those laid
39 off, and greater well-being.

53 Given the depth of the Great Recession, our prior expectation was that a rising prevalence of
54 insecurity, restructuring and other deteriorations in job quality would lead to a reduction in job-
55 related well-being in both dimensions. In what follows our aim is, not to test whether the Great
56

59
60
61
62
63
64
65

1
2
3
4 Recession *caused* changes in job-related well-being, but to investigate what happened and how
5 far factors associated with recession, such as restructuring and rising insecurity, were present
6 and are associated with job-related well-being. Specifically, we ask: what happened to the two
7 dimensions of job-related well-being between 2006 (before the recession) and 2012? How far
8 was the pace of restructuring and workplace change heightened in this interval? How did core
9 elements of job quality change between these two dates? In the light of our estimates of the
10 association of job characteristics and of workplace change with job-related well-being, we then
11 decompose the observed change into a part that can be ‘accounted for’ by accelerated
12 workplace change and by changes in job quality, and a residual that cannot be linked to
13 observed variables.

27 **Data and indicators**

28
29 To examine these questions, together with the hypotheses derived from the core theories, we
30 use data from the British Skills and Employment Surveys, a series of periodic nationally
31 representative sample surveys of individuals in employment which we have collected. Sample
32 sizes were 4,470 in 2001, 7,787 in 2006 and 3,200 in 2012; the full survey details are reported in
33 Felstead et al. (2002; 2007) and, for 2012, at <http://www.llakes.org/>. The surveys collected
34 responses from working adults interviewed in their own homes. Interviews lasted less than one
35 hour on average, no evidence of tiredness was observed and no interviews were abandoned
36
37 The samples were drawn using random probability principles subject to stratification based on
38 socio-economic indicators, and only one eligible respondent per address was randomly selected
39 for interview. Weights were computed to take into account the differential probabilities of
40 sample selection, the over-sampling of certain areas and some small response rate variations
41 between groups (defined by sex, age and occupation); all of the analyses that follow use these
42 weights.
43
44
45
46
47
48
49
50
51
52
53

54
55 We focus in our analyses only on employees, because some of the key variables under study are
56 likely to be interpreted somewhat differently by the self-employed. We collected data on job-
57 related well-being using Warr's scales in the 2001, 2006 and 2012 surveys. To measure the two
58
59
60

1
2
3
4 dimensions of job-related well-being – Enthusiasm and Contentment – a series of items was
5 introduced with the words: ‘Thinking of the past few weeks, how much of the time has your job
6 made you feel each of the following...?’, each followed by an adjective describing a different
7 feeling. For the Enthusiasm scale, the adjectives were ‘depressed’, ‘gloomy’, ‘miserable’,
8 ‘cheerful’, ‘enthusiastic’ and ‘optimistic’. For the Contentment scale the adjectives were ‘tense’,
9 ‘uneasy’, ‘worried’, ‘calm’, ‘contented’ and ‘relaxed’. Possible responses were ‘never’,
10 ‘occasionally’, ‘some of the time’, ‘much of the time’, ‘most of the time’ and ‘all of the time’.
11 Both scales are constructed by averaging the responses, having reversed the negative items,
12 ranged from 1 to 6. In our samples the Cronbach's alpha statistic was 0.81 for both Enthusiasm
13 and Contentment, suggesting that it is reasonable to regard the elements of each scale as
14 capturing an underlying dimension.
15

16 Work duration is indicated by the number of hours usually worked per week. We derived a
17 Work Intensity Index that includes multiple facets, constructed from the following elements: a)
18 the perception of required hard work; b) the frequency of working to tight deadlines; c) the
19 frequency of having to work at very high speeds; d) the frequency of experiencing difficulty to
20 complete tasks in time; e) the frequency of returning home from work exhausted; f) the
21 perception of putting in additional effort beyond requirements; g) average task demands
22 (derived from 40 items).³ These seven items were combined, after standardising, into a single
23 scale, with a Cronbach's alpha statistic of 0.72. Our findings described below are not sensitive
24 to reasonable alternative methods of constructing this index.
25

26 We generated the Task Discretion Index from four items which assess how much personal
27 influence people report over specific aspects of their jobs: how hard they work, deciding what
28 tasks they are to do, how the tasks are done and the quality standards to which they work. The
29 response options ranged from ‘a great deal’, ‘a fair amount’ to ‘not much’ and ‘not much at all’.
30 A summary index was constructed, by taking the average of responses of the four items. The
31 Cronbach's alpha coefficient is 0.77. We also include a measure of whether employees have
32 some influence over tasks through the teams they work in. We asked whether they worked in a
33

59 ³ These indicators of the importance of tasks in jobs are described fully elsewhere, e.g. Green (2012).
60
61
62
63
64
65

1
2
3
4 group, and if so how much influence the team had over the same aspects of the team's work.
5
6 We generated a dummy variable indicator for 'semi-autonomous' team, equal to one if the
7
8 employee worked in a team where the average amount of team influence was at least 'a fair
9
10 amount', zero otherwise. Our measures of participation are then supplemented by a dummy
11
12 variable indicating whether the worker has 'a great deal' of say in decisions that change the
13
14 way the job is done. Organisational involvement is indicated, first, by a dummy variable for
15
16 participation in quality circles. Second, we computed an indicator (range 0-8) for organisational
17
18 communications via meetings with management: the sum of the number of issues (finance,
19
20 investment, working practices, company products, health and safety, training plans and other
21
22 matters) that can be raised in consultative meetings and a dummy for information-giving
23
24 meetings. We also included an indicator for union voice: a dummy variable for whether unions
25
26 are present in the establishment and reported to have a 'fair amount' or 'a great deal' of
27
28 influence over work organisation.

29
30 Financial participation is captured by three dummy variables indicating whether the respondent
31
32 receives, as part of pay, a bonus linked to individual, team or organisational performance (the
33
34 latter including the facility to participate in a share ownership or option scheme).

35
36 To capture skills challenge we used four indicators. Two were dummy variables covering
37
38 whether the job required them to keep learning new things, and whether it never involved
39
40 carrying out short, repetitive tasks. The third indicator is how much variety there is in the job.
41
42 The fourth indicator captures how far respondents agreed with the statement 'I have enough
43
44 opportunity to use the knowledge and skills that I have'.

45
46 To capture job insecurity respondents were asked whether there was any chance of them
47
48 becoming unemployed and losing their job in the next twelve months, and if so how likely this
49
50 was on a five-point scale ranging from 'very unlikely' to 'very likely'. In previous studies it has
51
52 been shown that expectations of job loss are well-informed (Dickerson and Green 2009;
53
54 Stephens 2004).

55
56 Several measures of workplace change are also included. We ascertained whether skills used
57
58 had changed, respondents had been promoted or their choice over work methods had changed

1
2
3
4 since a recent reference point.⁴ While some will have changed employer since the reference
5 point, among those that did not do so we ascertained whether new technology (specifically,
6 new computerised or automated equipment) had been introduced, whether work had been
7 reorganised, and whether there had been some downsizing (specifically, a reduction in the
8 number of people doing the job). We would also liked to have included an indicator of wage
9 cuts, but this was not available in the data.

17
18

19 **A picture of job-related well-being and (non-pay) job quality in Britain, 2001-2012.**

20
21 The first question we address is whether job-related well-being has risen, fallen, or remained
22 stable through the recession. To set this in context, we also include the 2001 picture for this
23 description. Pooling the data from all three waves, and using a consistent base across years
24 (employees aged 20-60, living in England, Scotland or Wales) the Enthusiasm index has a mean
25 of 4.27 while Contentment has a mean of 3.72. Table 1 shows that there was no significant
26 change in job-related well-being between 2001 and 2006, but that in the next six years well-
27 being fell significantly in both dimensions. The change was quite substantial, amounting to
28 around 7% and 20% of the standard deviations of Contentment and Enthusiasm respectively.
29 Thus, while in theory the direction of change in job-related well-being for those still in
30 employment in a recession could not be predicted, in practice the direction of change through
31 the Great Recession was downwards.
32
33
34
35
36
37
38
39
40
41
42

43 The two indices can each be divided into sub-indices covering just the positive or just the
44 negative items. This is of interest because other studies using these scales may focus on just the
45 positive or the negative items. Table 1 reveals that declines in the Contentment index over
46 2006 to 2012 occur for both negative and positive items, though the negative items decline
47 somewhat more (0.24 compared with 0.11). With the Enthusiasm index only the negative items
48 decline.
49
50
51
52
53
54

55
56 ⁴ We asked respondents if they were in work 5 years prior to interview, and if so this would become their
57 reference point for subsequent change questions. If not employed then, they were asked the same question about
58 4 years, then if not employed at that point, again about 3 years. This device enabled us to heighten the number of
59 responses with qualitative information about recent workplace change.
60
61
62
63
64
65

1
2
3
4 Differences can also be observed between the changes in the well-being of males and females.
5
6 In the case of Contentment the index falls further for males than for females (0.24 compared
7
8 with 0.11), while with Enthusiasm the index falls for males but not at all for females.
9

10 Having established that job-related well-being declined in the 2006-2012 period, we now
11
12 examine what happened to the pace of workplace change and to our indicators of job quality.
13
14 As can be seen in Table 1, there was an increase in the Work Intensity Index, especially between
15
16 2006 and 2012 – a work intensification. Meanwhile working hours came down by a small
17
18 amount from 2001. Individuals' task discretion remained largely stable overall through the
19
20 decade. Starting in 2006 there was an increase in the prevalence of semi-autonomous
21
22 teamworking (from 14% to 18%), coupled by a small rise in the prevalence of team-based
23
24 performance-related pay (16% to 18%). Communication between management and workers
25
26 rose between 2001 and 2006 but thereafter stabilised. After 2006, the use of quality circles
27
28 declined by a small amount, and there was also a more substantial reduction in the share
29
30 reporting influence on changes in work methods (from 31% to 26%), while union voice and non-
31
32 team forms of performance-related pay were unchanged.

33
34 Skills challenges also went through small changes between 2006 and 2012, the most notable
35
36 being a rise in repetitiveness (a fall from 23% to 20% in the prevalence of jobs which never
37
38 entailed repetitive tasks), and a rise in the availability of opportunities for skill use.

39
40 There has been a rise in perceptions of the probability of job loss which accelerated after 2006:
41
42 whereas in 2006 83% of employees felt that there was no chance of losing their job, or it was
43
44 very unlikely, in 2012 the figure was down to 78%. Gallie et al. (2013) show that this rise was
45
46 complemented by a rise between 2000 and 2012 in fears of unfair treatment in the workplace.

47
48 As the table shows, rising insecurity after 2006 is also accompanied by alterations in the pace of
49
50 workplace change. Most notably, the proportion of employees reporting that there had been
51
52 some downsizing in their job rose from 30% in 2006 to 41% in 2012. There were also falls in the
53
54 prevalence of skill rises (58% to 54%), promotion (38% to 35%), workplaces with increasing job
55
56 choice (41% to 36%), job mobility to another employer (43% to 39%), and the introduction of
57
58

1
2
3
4 new technology (63% to 58%). These are the unsurprising accoutrements of the Great
5
6 Recession in Britain.

7
8
9 The relevance of these job characteristics and the altered pace of change for our understanding
10
11 of the changes in well-being depends on their associations with well-being, as implied by the
12
13 core theories outlined above. We now therefore turn to an empirical model of these
14
15 associations.

16 17 18 19 **The determinants of well-being.**

20
21
22 Table 2 presents our baseline model implied by core theories. We use the pooled nationally
23
24 representative data for 2006 and 2012, in order to focus on the period in which well-being fell
25
26 and because this enables us to use the full range of explanatory variables. This restriction allows
27
28 us to expand the base to all employees aged 20-65. Males and females are treated separately,
29
30 since different domestic circumstances (including labour market participation), preferences or
31
32 opportunities may condition the effects of job quality indicators in distinct ways according to
33
34 gender; also, as we have seen, their experiences differed through the recession. We use the
35
36 Seemingly Unrelated Regression estimator to allow for potential correlation of the residuals in
37
38 the regressions for the two well-being dimensions.

39
40 The findings confirm previous studies showing the negative association of work intensity with
41
42 well-being (H1). Concerning the non-linearity hypothesis (H2) the evidence is mixed. There is a
43
44 negative coefficient on the square of work intensity in all four cases, but this is significant (at
45
46 1%) only in the case of females' Contentment index. Another new finding is that the estimates
47
48 support the hypothesis (H3) that work intensity impinges more on Contentment than on
49
50 Enthusiasm. Evaluated at its mean (zero) the standardised effect of work intensity for females is
51
52 -0.55 on Contentment and -0.25 on Enthusiasm; for males, the equivalents are -0.39 and -0.27.
53
54 These differences are each significant at 1%.

55
56 As regards work hours the relationship with Enthusiasm is U-shaped, supporting H1 only up to a
57
58 point and H2 not at all: the working week at which Enthusiasm is at a minimum is estimated to
59
60

1
2
3
4 be 40 hours for men, 53 hours for women. This result is similar to previous findings in the
5 literature which have found somewhat high levels of job satisfaction among those working very
6 long hours (Benz 2005): this association is interpretable as reflecting the endogenous
7 determination of work hours, in that some of those work long hours are choosing to do so
8 because they enjoy the work.
9

10
11
12
13
14 The findings also confirm a substantive positive effect of individual task discretion on the two
15 dimensions of well-being (H4). Moreover, the interaction with work intensity is positive and
16 significant in three cases, consistent with previous evidence concerning hypothesis H5 that the
17 detrimental effects of work intensity are moderated by higher levels of task discretion.
18
19

20
21
22
23 Indicators of organisational participation are also positively associated with well-being (H6). The
24 strongest is 'influence on change in work method', which is significant for both dimensions and
25 sexes; as an example, for females having 'a great deal' of say in organisational decisions that
26 change the way work is done and has an effect on Enthusiasm of 0.26 (31% of its standard
27 deviation). Semi-autonomous team-working (with high levels of team influence over tasks) has
28 lower coefficients, yet these are significant in 3 out of 4 cases. Quality circle participation is
29 associated with greater Enthusiasm for males, while the Organisational Communications
30 indicator is linked with Enthusiasm for both sexes. Union voice is beneficial in raising
31 Contentment for males.
32
33

34
35
36
37
38
39
40
41 Unlike earlier studies which report negative effects of individual-based financial participation,
42 we find that receipt of individual or team-based pay is found to be insignificant. Financial
43 participation through organisation-level performance schemes, however, is associated with
44 significantly lower Contentment for males, weakly supporting H8 rather than H7.
45
46
47

48
49 The extent to which jobs are challenging is important in several ways. The estimates are
50 consistent with previous studies, in that they show strong positive associations between the
51 opportunity for skill use and well-being, and between job variety and well-being (H9). To
52 illustrate how strong this effect is, for males the difference between a job with 'a great deal' of
53 variety and one with 'some', 'little' or 'none', is 0.35 on the Enthusiasm scale, that is, 42% of its
54 standard deviation. In addition, Warr's hypothesis (H10) is confirmed for both these variables,
55
56
57
58
59
60

1
2
3
4 in that the estimated link with Enthusiasm is greater than the link with Contentment. The
5 coefficients differ significantly: thus, for 'Great Deal' of variety $p=0.00$ for both sexes; for
6 'Strongly disagree' about enough opportunity for skill use, $p=0.00$ for females, $p=0.08$ for males.
7
8
9

10 In respect of the requirement to learn new things ('Learning'), the estimates show the expected
11 positive association with Enthusiasm (significant for females), but for males the association with
12 Contentment is significantly negative. Avoidance of repetitive tasks in a job is associated with
13 greater Enthusiasm for males and, for both sexes, lower Contentment. Thus, with both these
14 indicators, H10 may need amendment to a stronger version: the effect of skills challenge on
15 Contentment is not only less than its positive effect on Enthusiasm, it may become negative.
16
17
18
19
20
21

22 Finally, as predicted job insecurity is associated with lower well-being in both dimensions (H11).
23 This effect is large: for example, those females who think that they are 'quite likely' or 'very
24 likely' to be losing their jobs in the coming year have a Contentment level of 0.31 (35% of sd)
25 less than the reference category of secure employees.
26
27
28
29
30
31

32 33 **A robustness issue: controlling for personality** 34

35
36 Table 2 shows that, taken together, the job characteristics account for between 15% and 20%
37 of the variation in our measures of job-related well-being. Since these are cross-sections,
38 however, the estimates do not establish causation. For the usual reasons, many of the job
39 characteristics could be argued to be partially affected by other variables which also affect well-
40 being, of which a prime candidate is personality; there could also be reverse causation.
41 Moreover, it could be that the selection of individuals into employment is related to their well-
42 being, which would also make for potential bias. Nevertheless, one could have greater
43 confidence that the estimates are worth taking seriously as showing consistency with theory
44 where it is possible to control for personality and other relevant personal characteristics. We
45 therefore investigated whether the addition of such controls substantially altered the pattern
46 of findings just described. To do this, our analysis was confined to the 2012 data, which
47 contained indicators of the 'Big Five' personality traits – Extraversion, Agreeableness,
48
49
50
51
52
53
54
55
56
57
58
59
60
61
62
63
64
65

1
2
3
4 Conscientiousness, Emotional Stability and Openness. We included the scales derived from the
5 short form version of these scales, designed and validated for use where interview time was
6 scarce in large-scale surveys (Gosling et al. 2003; Muck et al. 2007).
7
8
9

10 The full results of this exercise are given in an Appendix, available on request to the first author.
11 As expected, the introduction of the personality variables substantially increases the amount of
12 well-being variation that is accounted for, for females reaching 37% for Enthusiasm and 30% for
13 Contentment. Emotional Stability is especially strongly associated with both dimensions of well-
14 being. The key observation, however, is that the estimated effects of the job quality variables
15 do not greatly differ from those using the same specifications used in Table 2. The same
16 observation holds for the further inclusion of demographic controls, which include age,
17 ethnicity, education level, childhood financial security and parental interest in their school
18 progress. Thus, despite the power of the personality variables to influence well-being, their
19 effects and those of other controls appear to be largely orthogonal to the job quality variables
20 of interest.
21
22
23
24
25
26
27
28
29
30
31

32 33 34 35 **Extension: workplace change and well-being**

36
37 Table 3 extends the basic model of well-being to incorporate workplace change. In addition to
38 the job quality variables entered into Table 2, we introduced dummy variables for changes in
39 respondents' jobs, whether the respondent changed employer, and if not whether he/she
40 experienced the various workplace changes noted in Table 1. These additions are subject to
41 the same issue of endogeneity discussed above; in particular, individuals who in their past
42 employment had a higher well-being (which could persist into the present) might be less likely
43 to change jobs. We therefore look only for associations, not proof of causation.
44
45
46
47
48
49
50

51 The table shows no significant associations with rising skills requirements, but promotion is
52 associated with greater Enthusiasm for males, and lower Contentment for females. Decreased
53 choice has detrimental effects for both dimensions for both sexes, while increased choice is
54 beneficial for the Enthusiasm of females. Having changed employer is associated with lower
55
56
57
58
59
60

1
2
3
4 Contentment. Among workplace changes, work re-organisation and (strongly) downsizing each
5 have significant negative associations with well-being for both dimensions for both sexes. Males
6 who report downsizing, for example, have an Enthusiasm index that is 0.14 (17% of sd) lower
7 than that of others where there is no downsizing. Since these models also contain, as controls,
8 the same variables that were included in Table 2, these effects are supplementary to any links
9 that workplace change may have had with job characteristics and thence with well-being.
10
11
12
13
14
15
16
17
18

19 **Decomposing changes in well-being.**

20
21 We are now in a position to present, in Table 4, a conventional decomposition of the 2006-2012
22 falls in well-being into those that can be 'accounted for' by changes in the job quality variables
23 and the workplace change variables, and those that remain unaccounted for by our observed
24 variables. We use a simple pooled model of the 2006 and 2012 waves, with the same covariates
25 as in Table 3.
26
27
28
29
30

31 For the Enthusiasm index we focus on males only since for females there was no significant
32 decline to account for. Of the fall of 0.108 in the Enthusiasm index for males just over a fifth
33 (21%) is accounted for by the effort and participation variables combined, while another equal
34 proportion is down to workplace change. Overall, the model accounts for 37% of the decline,
35 and the rest can only be put down to unobserved variables.
36
37
38
39
40

41 With the Contentment index, nearly a fifth (19%) of the 0.219 decline for males is accounted for
42 by changing effort and participation. This share is added to by workplace change and insecurity,
43 but partly counterbalanced by an improvement in skills challenge. As a result, overall nearly a
44 quarter (24%) of the decline is accounted for. For females, nearly a quarter (24%) of the smaller
45 decline of 0.115 is accounted by effort and participation; workplace change and insecurity
46 together add a similar amount; however, skills challenge provides a substantial counterbalance.
47 Overall, 37% of the fall is accounted for.
48
49
50
51
52
53
54
55

56 Thus overall, while some of the declines in well-being are accounted for by observed workplace
57 change and changing job quality, only a minority share is 'explained' in this way. The
58
59
60
61
62
63

65

1
2
3
4 'unexplained' parts of the declines can be attributable to unobserved variables with predicted
5 high influence on well-being, about which one can speculate. One possibility is the wider forms
6 of insecurity (fear of unfair treatment and unwanted role alteration) which are known to have
7 risen substantially between 2000 and 2012 (Gallie et al. 2013). Another is pay cuts: with median
8 real wages falling since 2008, there will have been a substantial rise between 2006 and 2012 in
9 the number of employees experiencing reductions.

19 **Conclusion.**

20
21 In this paper, we have applied a model derived from several core theories of job-related well-
22 being to a large nationally-representative sample of Britain's workers, and examined how job-
23 related well-being changed between 2006 and 2012, that is, before and after the deepest
24 recession to affect capitalist countries since at least the 1930s.
25
26
27
28

29
30 Our first substantive new finding is that there was a substantial fall in average job-related well-
31 being over the 2006-2012 period surrounding the Great Recession, while over the same period
32 there were some significant changes in job quality (increases in work intensity, insecurity and
33 the pace of workplace change). For males, both Enthusiasm and Contentment fell, while for
34 females only Contentment fell. These findings contribute to our understanding of
35 macroeconomic and societal change, and attest to the potential benefit for national statistical
36 offices to collect valid data and incorporate measures of well-being in their national
37 assessments.
38
39
40
41
42
43
44

45
46 Tests using the model showed some new findings concerning the determinants of job-related
47 well-being:
48

- 49
50 • We found that there is only weak evidence that the marginal effect of effort on well-
51 being is increasingly negative (H2); the hypothesis could only be supported in the case
52 of the effect of work intensity on females' Contentment.
53
- 54 • We also report new findings concerning the effects of financial participation (where
55 theory suggests either positive or negative effects). Our estimates implied that practices
56
57
58
59

1
2
3
4 that connect organisational performance with rewards are linked with lower
5 Contentment for males (H8, rejecting H7). However, the receipt of other forms of
6 performance-related pay has no significant association with job-related well-being. For
7 these other forms one can conclude, either that the effects are weak, or that opposing
8 effects are balanced.
9

- 10 • We found that downsizing, work re-organisation and decreased choice are each
11 associated directly with lower job-related well-being (H12).
12
- 13 • As predicted, we also found that some effects on job-related well-being differed
14 according to the dimension of well-being. Work intensity has a more (negative)
15 association with Contentment than with Enthusiasm (H3). Job variety and opportunities
16 for skills use have more of a positive association with Enthusiasm than with
17 Contentment (H9 and H10). Moreover, we find that some indicators of skills challenge
18 (learning requirements, non-repetitiveness of tasks) are associated with higher levels of
19 Enthusiasm but lower levels of Contentment (H9 and H10).
20
21
22
23
24
25
26
27
28
29
30
31

32 Our findings also confirmed results from previous studies, many of which have been obtained
33 using non-nationally-representative data. Thus we found that task discretion has a large
34 positive association with job-related well-being. Moreover, this link interacts with work
35 intensity as predicted, so that, while high work intensity is associated with low job-related well-
36 being (H1), task discretion is more effective at higher levels of work intensity (H5). Decision-
37 making organisational participation is found to be associated with higher well-being (H6), the
38 main channels being through having an influence on changes in work methods, and through the
39 influence obtained in semi-autonomous teams. We also re-confirmed the well-established
40 negative association between job insecurity and lower well-being (H11).
41
42
43
44
45
46
47
48
49

50 The model estimates accounted for a minority part of the decline between 2006 and 2012 in
51 both dimensions of well-being. The variables that were driving this 'explained' decline were
52 those typically associated with recession: downsizing of establishment size, rising job insecurity
53 and work intensification not accompanied by rises in task discretion or organisational
54 participation in decision-making. The opportunity to utilise skills increased and improved well-
55

62
63
64
65

1
2
3
4 being slightly, and this appears to have contributed a little to the observed gender difference in
5 declining well-being. Nevertheless, there remains a substantial part of the decline that is
6
7
8 'unexplained', which has to be put down to unobserved factors.
9

10 While in most instances the association of job quality variables with job-related well-being is
11 the same for males and females, we draw attention to two differences of note for further
12 research. First, while being promoted is, unsurprisingly, associated with greater Enthusiasm for
13 males, for females there is no such effect; indeed, promotion appears to bring significantly
14 lower Contentment. Whether this negative effect on Contentment is induced by the
15 enhancement of job roles at a lifecourse stage when women are also bearing major domestic
16 responsibilities deserves further examination. It may be especially relevant in the context of
17 findings that gender gaps in job quality appear to be negligible at the start of working life, but
18 to open out as careers develop (Manning and Swaffield 2008). Second, working in a good
19 learning environment is positively associated with Enthusiasm, in the case of females; for
20 males, however, not only is there no significant relationship with Enthusiasm, it is associated
21 with lower Contentment. Whether this is due to different aspects of learning environments in
22 the jobs typically done by men and women, or whether to gender-based differences in learning
23 dispositions, also merits further investigation.
24

35
36
37

38 When analysing job quality and well-being, surveys of individuals (who are, after all, the job-
39 holders and therefore best-placed informants on what happens in their jobs) are preferable to
40 surveys of employers. Individuals are, of course, sometimes open to social esteem bias, so
41 questionnaires have to be designed with care to minimise its occurrence. Moreover large,
42 representative, samples taken at successive timepoints have the merits that findings are
43 generalisable and that valid descriptions can be developed about how a nation, region or other
44 aggregate entity is changing. While the results in this paper apply to Britain, the hypotheses are
45 relevant everywhere. It seems quite possible that job-related well-being may have followed
46 similar patterns in other countries experiencing the recession, even if each experience may be
47 modified by country-specific institutions. If the data could be collected elsewhere, the same

4 methods could be used to track and account for job-related well-being over time, and how this
5 relates to macro-level events.
6

7
8 Nevertheless, it needs to be remembered that respondents in nationally-representative
9 samples of workplaces will differ in many ways. Some variables may have varying meanings
10 according to their setting, while other determining characteristics remain unobserved. This last
11 point leads to the chief limitation of our analyses, which is that they have been conducted with
12 successive *cross-sections*. One step we have taken in this paper to reduce potential endogeneity
13 biases is to include a wide array of variables and controls, even though there are ultimate limits
14 to how many determinants can be captured in a survey. Our most notable innovation, however,
15 is that in the latest wave we have included controls for personality traits, the 'Big Five'
16 measured in short form, since it could be held that these would influence the allocation to jobs
17 as well as being strongly correlated with subjective well-being. Reassuringly, the estimated
18 associations of our baseline model variables with well-being showed no or only small changes,
19 when family background and personality controls were introduced. Nevertheless, given that
20 there are likely to be other unobserved person-specific factors affecting the allocation of labour
21 none of the estimates can be regarded as unbiased estimates. In the absence of nationally-
22 representative panel data with equally rich job quality data, our findings summarised above
23 should be regarded as showing consistency with the hypotheses, rather than proving causal
24 effects.

41
42 Economic downturns are to be avoided if possible through macroeconomic management, and
43 the effects of rising insecurity and accelerated disruptive workplace change on job-related well-
44 being provide yet more reasons to do so. But if downturns occur it may be suggested that the
45 control of work intensity and a better design of jobs could ameliorate some of the detrimental
46 effects on well-being. The estimates, if taken at face value as deriving from causal effects, point
47 to the need for more individual or team-level task discretion, greater variety (while controlling
48 the level of required effort), more efficient use of skills, and a say in matters of work
49 organisation. Organisational participation at a higher level, for example through better
50 communication or a union voice, is also found to be valuable though of lesser import. By

- i. The base is all employees Aged 20-60.
- ii. DV: 0-1 dummy variable. All variables are defined in theData and Indicators section of the text.
- iii. PRP: performance-related pay.
- iv. + Applies to those in employment at a past reference point; ++ applies to those who remained in the same job since the reference point. (The reference point is 5 yrs previously or, if not in employment then, 4 years previously or, if not in employment then, 3 years previously) .
- v. Changes significantly different from zero at levels: *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$.

Note.

The asterisks indicate whether the changes and 'explained' changes differ significantly from zero: *** p<0.01, ** p<0.05, * p<0.1. 'Explained' differences are those associated with between-year differences in the explanatory variables (those used in Table 3).
