ABSTRACT

Accountability pressures have generated complex performance measurement regimes to evaluate and improve public or publicly-funded services. Performance management, however, faces many challenges including the tradeoffs posed by numerous dimensions of performance and a lack of consensus on which organizational and environmental factors can improve these results. This study seeks to understand the effect of management and other factors on different dimensions and measures of performance in U.S. public, nonprofit, and for-profit nursing homes. Using a hybrid data set that combines archival government data on performance in nursing homes with a recent nursing home administrators' survey, we find that innovative management significantly¹ improves the quality of care. In addition, more innovation and less power sharing in management are associated with serving fewer Medicaid-funded clients. Significant differences in performance exist across public, nonprofit, and for-profit organizations. These differences are notable across both the archival and perceptual models of performance.

¹ Throughout the paper, the term "significance" refers exclusively to "statistical significance."

Management and Performance in U.S. Nursing Homes

INTRODUCTION

Organizational performance is an increasingly global concern for public administration scholars and practitioners (Boyne, Meier, O'Toole and Walker 2006; O'Toole and Meier 2011; Radin 2006). Across service areas, mounting accountability pressures motivate the creation of complex performance measurement systems to help evaluate and improve public or publicly-funded services (Andrews, Boyne and Walker 2006a; Heinrich 2012; Heinrich and Marshke 2009; Selden and Sowa 2004). Among the challenges to the use of performance data are tradeoffs posed by numerous dimensions of performance and a lack of consensus on which managerial, organizational, and environmental factors can improve these results. Related to these challenges, rigorous empirical research that identifies such factors is limited. This research contributes to our discipline's quest for administrative means to achieve public goals. We seek to understand the effect of management and other organizational and environmental factors on numerous dimensions and measures of performance in public, nonprofit, and for-profit organizations – with U.S. nursing homes as the empirical settings. An increasingly salient public policy area in the U.S. due to the growth of elderly population, this field is a good example of a policy-specific performance measurement system, with its intergovernmental and cross-sector relationships, unique complexities, biases, and perverse incentives.

This paper makes several contributions to public management and health policy literature. First, we focus on three broad areas of organizational management – innovation, sharing power, and external management. Our findings suggest a significant and positive association between innovation management and service quality. Innovation and power sharing are also significantly related to greater access to care. Notably, after including management in

the analysis, public, nonprofit, and for-profit ownership remains a key factor in explaining the variation in nursing home quality and access. Second, our study focuses on two dimensions of performance – service quality and access for low-income clients – using both the archival indicators and the perceptual managerial assessments. Our findings show marked differences in the managerial determinants of these dimensions and measures of performance. For this analysis, we use a hybrid² data set that combines government data on nursing home performance from the Centers for Medicare and Medicaid Services (CMS) with a nursing home administrators' survey of internal management strategies. Third, this study contributes to the health policy and health care administration literature. We find that innovation management, but not power sharing or external management, is associated with service quality in a health care market with fairly low service measurability,³ technological sophistication, dependent clientele, and extensive third-party financing and regulation. Our results may be more generalizable to other health and human services, as well as to the fields of long-term care in other developed nations, where higher employment rates, job-related mobility, substantial retirement benefits, and prevalence of nuclear families create demand for institutional long-term care.

LITERATURE REVIEW

Because this study examines both the measurement of organizational performance and its determinants, several research literatures are relevant. They include organization theory, public management, and health policy.

² For the purposes elaborated below, hybrid data are considered particularly useful in the public management literature (Boyne et al. 2006).

³ The effect of management and other factors may differ in the context of higher service measurability, i.e., with more observable, verifiable, and quantifiable outcomes. Similar to other human services, long term care clients' improvement can be hard to measure. It is also hard to connect client outcomes to the care interventions that typically involve high levels of professional discretion. Despite this, quality assessment of US nursing homes is fairly elaborate, capturing inputs, processes, outputs, and outcomes with an extensive list of CMS measures.

Organizational Performance and the Sources of Data. Defined broadly as “the character and consequences of service provision by public agencies,” public sector performance is a socially constructed and multi-dimensional phenomenon (Brewer and Selden 2000; Forbes, Hill and Lynn 2006, 255). Understanding the sources of performance improvements, including management, is a gargantuan task for a number of reasons (Boyne 2002; Lynn, Heinrich and Hill 2000). Government agencies often have conflicting values and objectives, and their attainment involves making tradeoffs (Brewer 2006; Weiss, Bloom, and Brock 2014). Also, many stakeholders are involved in the collection and use of performance data, making it difficult to develop a coherent picture of performance improvement (Andrews, Boyne and Walker 2006b; Radin 2006). Finally, performance management goes beyond the “rational” analyses, and involves political, cultural, and other considerations (Eggleston and Zeckhauser 2002).

The many objectives of government agencies are reflected in a range of *dimensions* of performance related to organizational inputs and processes (e.g., management, structures, resources, efficiency, or fairness), outputs (e.g., quality or timeliness), and outcomes (e.g., client or community impacts) (Addicott and Ferlie 2006; Boyne 2002; Forbes et al., 255).

Understanding and accounting for this complexity requires innovative theory-building and rigorous research methodology – both applied to a rich set of relevant data. Furthermore, when the reality is complex, the measurement can hardly be simple. Measures that lack validity and reliability are of little use to practitioners (Meier and O’Toole 2013a). The literature highlights an important distinction between *archival* and *perceptual* measures of performance. Reflecting the managers’, staff, or clients’ views on services, *perceptual* measures allow comparability of data across services or jurisdictions. Client surveys, in particular, are considered valid and relevant for public management (Shingler, Van Loon, Alter and Bridger 2008; Van Ryzin,

Immerwahr and Altman 2008). Perceptual measures can be problematic: they often include non-random measurement error and are prone to positivity bias (Boyne et al. 2006).⁴ Perceptual measures can also entail common source bias, when systematic error variance is shared among several variables from the same source (Meier and O’Toole 2013a).⁵ Data from *archival* sources are developed by professionals in a standard fashion to minimize discretion and organizational biases. Archival measures may fail to capture all organizational outcomes,⁶ and may result in dysfunctions – cheating, creaming, or goal displacement. Nonetheless, archival measures are widely regarded as the “gold standard” of performance measurement, ranging from standardized tests, to agency-wide scores and societal indicators⁷ (O’Mahony and Stevens 2006). Empirical studies across fields suggest that perceptual and archival measures of quality, quantity, or equity are not strongly correlated (Andrews, Boyne and Walker 2006b; Bommer et al. 1995; Brown and Coulter 1983; Kelly and Swindell 2002; Meier and O’Toole 2013b; Van Ryzin et al. 2008).⁸ Examinations of the effect of various determinants on both the perceptual and archival measures are scarce, and the findings are mixed (Amirkhanyan, Kim and Lambright 2014; Shingler et al. 2008). Our analysis relies on archival measures of performance reflecting the nursing homes’ compliance with federal regulations of the quality of life, care, administration, and physical environment; as well as access to care for Medicaid-funded clients. The goal of this study is to investigate how performance is related to management, and various organizational and environmental factors (such as ownership, size, staffing, or competition). We supplement our

⁴ Meier and O’Toole (2013a) find that managers tend to report favorably on their practices and organizational successes, even after accounting for task difficulty or resource constraints.

⁵ Thus, relationships between variables can be inflated or deflated (Meier and O’Toole 2013b). Although there are better and worse ways of addressing this issue (Favero and Bullock 2015), no method is perfect. Perceptual measures work better if they involve narrowly defined dimensions of performance (Meier and O’Toole 2013b).

⁶ Archival data may reflect judgments of powerful stakeholders on elements of performance.

⁷ These include, but are not limited to, life expectancy, disease rates, or literacy.

⁸ Meier and O’Toole (2013b) find correlation coefficient typically ranges between 0.2 and 0.6. Since the shared variance is the square of the correlation, this suggests rather sizable differences between the two types of measures.

analysis with the administrators' perceptual assessments of their facilities, to contribute to the literature on the antecedents of perceptual and archival performance data.⁹

Management and Organizational Performance. Public managers and policy makers can rarely improve the outcomes directly. Instead, they manipulate the antecedents even if there is little conclusive research on the determinants of performance (Boyne 2003; Forbes et al. 2006, 255). The sources of performance improvement are numerous: financial and human resources, organizational structure (e.g., centralization, size, and formalization), ownership, support by external stakeholders, market conditions, culture, client traits, and many others (Amirkhanyan, Kim and Lambright 2008; Boyne and Meier 2009; Brewer and Selden 2000; Lynn et al. 2000; Pandey and Moynihan 2006). Accounting for these factors in a given field is crucial in understanding the main drivers of service improvements.

Of the many internal and external determinants, organizational management has emerged as an important point of leverage (Boyne, et al. 2006). Studies confirm that management capacities and practices positively influence dimensions of organizational performance in the fields of human services, public education, and law enforcement (Andrews et al. 2006a; Boyne 2003; Brewer 2006; Moynihan 2008; Moynihan and Pandey 2005; Nicholson-Crotty and O'Toole 2004; O'Toole and Meier 2011; Selden and Sowa 2004). In public administration, the questions of how to conceptualize management and what its impacts are on performance are fundamentally important (Forbes et al. 2006, 255; Lynn et al. 2000). Managers pursue an almost limitless plethora of specific activities: framing the goals, setting up internal and external structures and levels of supervision, motivating/incentivizing the participants, shaping cultures, building partnerships, complying with mandates, or adopting best practices of the field (Forbes et

⁹ This will provide important evidence on the propensity of subjective measures to suppress or falsely identify relationships with variables commonly included in organizational performance models.

al. 2006: 255; Kenis 2006; Lynn et al. 2000; Rainey and Steinbauer 1999). While it is difficult to account for all of these distinct, micro-level activities, many of which are specific to the service context, some scholars focus on the broader, overarching areas of management.

We focus on three such broad areas. The first and second areas of management refer to the internal and external focus of managerial activities, respectively. Thus, managers work *within* organizations, and in managing staff and organizational processes, their approach to organizational governance can vary from power sharing to more centralized control. Externally, managers handle the environment and its influences on organizations. The third broader area is innovation management. Reflecting the managers' propensity to facilitate organizational change and learning by exploring new ideas and practices, it bridges the internal and external organizational settings. These three areas are central to the health care and nursing home care context, as the literature review suggests. Below, we elaborate on the how these three broader areas of management are related to organizational performance.

First, numerous influential theory-building studies in public management have focused on the extent of *shared power* while managing within organizations. Moynihan and Pandey (2005) find that centralization and limited staff autonomy stifle the efforts to make positive changes, while shared decision-making can improve performance. Brewer and Selden (2000) stress the importance of task structure – flexible management allowing the employees to make work-related decisions – in improving program outcomes. According to Boyne (2003), softer management styles, with attention to the employees' aspirations, rather than manipulation and control, may be a key source of program improvement. Additional literature explores overlapping and still evolving concepts of shared, democratic, participatory, or devolved management styles (Gronn 2008; Harris 2008). Participatory management reflects shared

decision-making beyond the distribution of positional power. It improves the employees' job satisfaction and sense of ownership; it also promotes efficiency, innovation, and knowledge-sharing, and reduces ambiguity and conflict (Dearden, Carter, David, Kowalski and Surridge 1999; Kim 2002; Oshagbemi and Gill 2003; Raelin 2012). A related concept of distributed leadership calls for focusing on a collective dynamic, where senior and middle managers and line staff all contribute to managing and leading (Fitzgerald, Ferlie, McGivern and Buchanan 2013; Harris 2008; Hargreaves and Fink 2008). Shared management can be motivated by the administrator's desire to gain support (Oshagbemi 2004), motivate the staff, or extend opportunities to participate in governance (Hargreaves and Fink 2008). In health care, distributed leadership enables service improvements and staff engagement (Rondeau and Wagar 2001; Tomlinson 2012). Nursing home managers, however, tend to prioritize state standards and efficiency over staff empowerment (Deutschman 2005).

More recently, the *external* orientation of management has been acknowledged. In today's boundary-less context, policies are implemented in multi-organizational arrangements where other entities that may not be fully supportive of individual agencies' missions (Rainey and Steinbauer 1999). O'Toole and Meier's (2011) theory of public management argues that organizational outcomes depend on the manager's ability to exploit and buffer the external influences. While attending to the productive core of their organizations, administrators *manage outward* and pursue *boundary work*: protect their organizations' autonomy, build support, procure resources, take advantage of partnerships, co-produce results, engage in external politics, reduce uncertainty, limit potentially hostile forces, and overcome obstacles (Meier and O'Toole 2003; Moore 1995; Rainey and Steinbauer 1999; Yan and Louis, 1999). Similarly, studies on collaborative and network management document managers' involvement in initiation, execution

and assessment of joint programs and development of joint rules with the external actors (Agranoff and McGuire 2003; Berry et al. 2004; Bryson, Crosby and Stone 2006; Thomson and Perry 2006). Nursing home administrators, similar to other public managers, report spending a considerable amount of time dealing with external issues (Castle, Ferguson and Hughes 2009).

Finally, *innovation management*, especially relevant to the context of this study, may affect organizational performance. Innovation is a process of changing the established organizational objectives and structures and how new ideas and practices spread and are “reinvented” throughout social systems has received considerable attention in social science research (Rogers 2003; 2004). Management is viewed as critical in the implementation of innovation (Berry 1994; Gabris, Grenell, Ihrke and Kaatz 1999; Stewart and Kringas 2003). In networked environments, innovation management is multi-pronged: it involves attending to new information, linking actors, reducing complexity, altering preferences, shifting structures, and building norms (O’Toole 1997). Increasingly, managers innovate by tailoring actions to the context (Ortt and van der Duin 2008). In nursing home care, leaders pursuing innovations lower costs and address organizational flaws (Deutschman 2005). The use of new technology (such as medication distribution technology) was found to enhance performance by helping to detect errors and build patient-focused care (Baril, Gascon and Brouillette 2014). The managers’ role is important in nursing homes, since nursing home employees are somewhat unfavorable to cultural change (Palmer et al. 2013). We include measures of sharing power, innovation, and external management, to explore their effect on care quality and access.

Other Determinants of Performance. In addition to management, other organizational and environmental factors are related to performance. Organizational *ownership* plays a central role: theories suggest that public, nonprofit and forprofit sectors play different roles in the

society and pursue different outcomes (Allison 1982; Rainey, Backoff and Levine 1976). While private organizations are expected to have greater efficiency, less red tape and politics, they are less likely to prioritize legal and political responsiveness (Cohen 2001). Contract failure theory suggests that in markets with notable informational asymmetries, public and nonprofit organizations outperform for-profit firms because they do not distribute profits to organizational owners (Hansmann 1987). In health care, public and nonprofit organizations are expected to be more patient- and quality-centered, while for-profits are mainly concerned with cost minimization (Eggleston and Zeckhauser 2002). While nonprofits are instrumental in serving the needs of those different from the average voter, the government sector often steps in when voluntary organizations fail and when equality of consumption is critical (Eggleston and Zeckhauser 2002; Hansmann 1996; Salamon 1987).

Empirical research on public-private differences is mixed, with some evidence of private sector superiority in cost minimization (Hodge 2000; Rainey and Chun 2005). As shown below, in nursing care, public and nonprofit homes deliver better quality of care than for-profits. When the direct measures of management are lacking, ownership is often used as a proxy for different management strategies. This paper re-examines the effect of organizational ownership, after separating out the effect of three management variables. Recognizing the importance of multivariate analysis that controls for location and adjusts for environmental risks (Smith 2006), we include other independent variables, such as staffing, size, occupancy, affiliation with a hospital, changes in ownership, organizational age, market competition, number of hospitals, home health agencies and hospices in the county, population density, percent of elderly, whites, and those in poverty. We discuss these factors in more detail below.

The Context of Nursing Home Care. As a result of increasing longevity and decreasing fertility in the U.S., the quality of long-term care is a salient public policy issue (Government Accountability Office 2015; Kinsella and Velkoff 2001; Thomas 2014). Nursing homes are an important element of the contemporary long-term care systems. These are residences that provide room, meals, and assistance with activities of daily living to individuals with complex chronic care needs. Most nursing homes in the U.S. are for-profit (approximately 65%), followed by nonprofit and public homes (28% and 7%, respectively) (Amirkhanyan et al. 2008). The industry can be characterized by a high degree of publicness for two reasons.¹⁰ First, federal, state, and local governments are *direct providers* of nursing care. Originating from public almshouses, nursing homes were created to serve the veterans, elderly, and disabled indigent individuals. While the Medicaid and Medicare programs incentivized private providers to enter the market, numerous governments continued to operate nursing homes (Amirkhanyan 2007; 2008; 2009). Second, federal, state, and local governments are involved in financing and regulation of nursing homes. Nursing home care is fair costly (Levit et al. 2000). According to the Nursing Home Compare (NHC) data used in this study, in 2012, care received by 60% of nursing home residents was reimbursed by Medicaid, while 16% were reimbursed by Medicare, and 25% had private long-term care insurance or paid out-of-pocket.¹¹ To be eligible for federal funds, nursing homes must comply with federal and state mandates set forth by the Social Security Act and the Nursing Home Reform Act of 1987 (Kane 1998). The CMS establishes the federal guidelines, while the states enforce them through licensure and inspections. The choice of

¹⁰ Following Bozeman, in this context, we use the concept of publicness that goes beyond organizations' legal status, but incorporates broader factors, such as the oversight of political actors, and influence of the public and other stakeholders (Bozeman 1987; 2013). As elaborated above, both public and private nursing homes are financed by federal government programs and closely regulated by state government regulators.

¹¹ The Veteran's Administration nursing home operations account for a small portion of the 25% of residents not covered by Medicaid and Medicare (Thomas, n.d.). However, we were not able to find any sources specifying the exact share for this market.

clients by providers, however, is not regulated in private homes (Freeman 2000). The latter motivates our focus to examine access to care as a dimension of performance.

Theories of nursing home markets suggest key differences across ownership (Davis 1993; Scanlon 1980). The traditional assumptions of supply and demand do not work here due to the lack of consumer knowledge, minimal movement across providers, and third party payments. This results in informational asymmetries and limits the effect of reputation. As a result, for-profit “Medicaid mills” serve poorer, sicker and less informed clients and divert resources away from services (Castle and Shea 1998; Harrington, Woolhandler, Mullan, Carrillo and Himmelstein 2001; Lemke and Moos 1989). Meanwhile, nonprofit providers tend to cultivate quality, which helps attract more informed, affluent clients. Nonprofit homes have better physical environment, equipment, and resident control; they evoke fewer complaints and deficiencies (O’Neill, Harrington, Kitchener and Saliba 2003; Santerre and Vernon 2005). In summary, in the private sector, attainment of quality and access is a zero-sum game. A small number of public homes have the safety-net role while providing high quality care (Amirkhanyan et al. 2008).

While data on regulatory violations (or deficiencies) and staffing levels have been publicly available for decades, more recently, in an effort to simplify these indicators, five-star ratings of quality were developed (CMS n.d.a) based on a complex formula using data on staffing, regulatory violations, and other factors (Thomas 2014). Similar to other government inspections, nursing home inspections and star-ratings combine both archival (regulatory) and perceptual (observation-based and self-reported) data (Andrews et al. 2006b).¹²

¹² The neutrality and unbiased nature of nursing home performance ratings created by the CMS may be undermined by several factors. First, performance assessment has high financial stakes: this marketplace is fairly litigious, and insurers may consider facility ratings during referrals. These pressures could produce perverse incentives for

This study examines the relationship of management, ownership, and other organizational factors to nursing home quality and access for Medicaid-funded clients. Existing research on nursing home quality has been primarily based on archival data with no management controls.¹³ Research on “best practices” in nursing care provides limited evidence on the central role of management (Compas, Hopkins and Townsley 2008). As noted in the Introduction, our study contributes to the nursing home care literature by examining the effect of three distinct management practices, organizational ownership, and other factors on numerous measures of care quality and access.

METHODOLOGY

Data. We used data from three sources. The NHC is the official public dataset generated by the CMS (CMS, n.d.b) created as a part of the quality assessment and certification process of all Medicaid or Medicare certified providers. State governments enforce national quality standards using trained inspectors who conduct nursing home site visits every nine to fifteen months. The team evaluates a nursing home’s compliance with over 180 federal and state regulatory standards in the following categories: quality of care, resident behavior and facility practices, resident assessment, resident rights, physical environment, dietary services, pharmacy services, and administration and regulation.¹⁴ To verify compliance, state inspectors review clinical and staffing records and interview residents, family members, and staff. A violation identified during a health inspection is recorded as a “health deficiency.”

While having perceptual and internal components, NHC is “archival” data: the inspectors

cheating and goal displacement (Thomas 2014). Also, the field is highly political, being influenced by consumer demands to improve care and the industry’s attempt to minimize regulation (Edelman, 1997-1998).

¹³ These studies suggest that staffing and nonprofit ownership are associated with fewer regulatory violations, while rural location, chain affiliation, size, competition, payment constraints, and percentage of clients on Medicaid are associated with more violations (Amirkhanyan 2008; Townsley, Bech and Pepper 2013; Harrington et al. 2001).

¹⁴ For a complete listing and explanation of these deficiencies, see CMS (2015a).

are external and are, to the extent possible, “detached” from the facilities. The inspections are based on a comprehensive tool applied in a standard fashion.¹⁵ The data are subject to review and appeal and considered an accurate and reliable indicator by scholars (Harrington et al. 2001). NHC is unbalanced facility-inspection level panel data. We have several observations pertaining to each facility, the most recent of which is related to the latest inspection conducted as of 01/01/2014 (i.e., 9-15 months prior to that date). The panel that we used (N=15,695) contains all Medicare and Medicaid certified nursing homes in the U.S. This dataset was merged with the Identifying University (XXXXX) Nursing Home Administrator Survey, the second source of data used in this study.

The (XXXXX) Nursing Home Administrator Survey was implemented between 01/2013 and 05/2013 (Identifying reference deleted 2013). The dates match well with the NHC data. The Survey was administered to all presently operating governmental nursing homes (n=903), and a random sample of 1000 for-profit and 1000 nonprofit homes. We oversampled public homes comprising a small share of the nursing home industry. A total of 725 administrators responded to the survey in three waves, with a response rate of 25%.¹⁶ After removing six duplicate records, the number of surveys was 716.¹⁷ As shown in Appendix A, our sample is similar to the population in terms of key characteristics tabulated by sector: number of beds, number of residents, percentage residents on Medicaid, nursing staff hours, hospital affiliation and both archival measures of quality. Our sample is somewhat more likely to include better performing

¹⁵ Like any inspection-based data, NHC has perceptual components. Inspectors may have ties with certain homes which may influence their assessments. Client and family interviews are also perceptual. Some data used for the 5-star ratings are self-reported by nursing homes and are therefore less “independent.” Star ratings are based on three components: health inspections conducted by outside reviewers, as well as self-reported data on staffing and on eleven different physical and clinical measures of residents’ experience (CMS 2015b; Thomas 2014).

¹⁶ The response rate is 20.1% for for-profit, 25.4% for nonprofit and 28.9% for government nursing homes. Our overall response rate compares favorably to a recent nursing home survey in the Netherlands (22%) reported by Van Eijk and Steen (2015)

¹⁷ Duplicate records occurred as a result of respondents’ filling out both the online and hard copy of the survey.

facilities, which has implications for the generalizability of our findings (see the Discussion section). Appendix A suggests that, despite its modest response rate, our sample is representative of the nursing home population. All fifty states and the District of Columbia were represented both in the fielded sample (2,903 homes) and the final sample (716 homes).

Finally, we used the Area Health Resource Files (AHRF) of the U.S. Bureau of Health Professionals. It includes county-level demographic and socio-economic data as well as information on the prevalence of health care organizations, by county.

Dependent Variables: Quality and Access. We use two alternative archival measures of nursing home quality. The first measure is *total number of health deficiencies* identified during a single inspection cycle. It includes both the deficiencies identified during a standard inspection and those identified due to a formal complaint by a party and verified by state surveyors. While theoretically this measure can range between 0 and 188, in our sample, the range was 0 to 31 (mean = 6).¹⁸ A large body of health policy literature has used and validated health deficiencies as a measure of nursing home quality (O'Neill et al. 2003). The second archival measure of quality is the *overall 5-star rating*, based on a formula incorporating: (a) 5-star health inspection rating, reflecting health deficiencies during the past three years, with recent results weighted more heavily; (b) 5-star staffing rating adjusted for the residents' needs; and (c) 5-star quality rating, reflecting the patients' clinical data. While used in the academic literature, the *5-star rating* has received criticism due to its provider-reported components (Thomas 2014). In our sample, the correlation coefficient between the *health deficiencies* and the *overall 5-star rating* is -0.52 (5-star rates quality, while deficiencies rate a lack of quality).¹⁹

¹⁸ Most homes have few violations: 10% of inspections had 0 violations, 50% had < 5, and 90% had < 12.

¹⁹ In the population, this coefficient is -0.54, and in the fielded sample, it is -0.56.

As a supplemental measure of quality – *perceived nursing home quality* – we used six items from the (XXXXX). In the regression, we used the factor score for this measure.²⁰

To what extent do you agree or disagree with the following statements? (Response categories: strongly agree (4), agree (3), disagree (2) and strongly disagree (1)).

1. Our nursing provides outstanding quality of care.
2. Our facility ensures a clean, safe, home-like and comfortable physical environment.
3. Our nursing home is known for ensuring that the residents' rights are always respected.
4. Our nursing home is known for providing choices to the residents and satisfying their preferences.
5. My nursing home meets the needs of the community it serves.
6. This nursing home is considered to be one of the best of its type in the state.

We used several measures of access reflecting a home's propensity to serve financially disadvantaged clients. *Percent residents on Medicaid*²¹ was obtained by the authors from the CMS. Nursing homes with a higher share of residents on Medicaid are argued to be resource poor due to lower reimbursement-to-cost ratios (Castle 2005, 64; The Lewin Group 2002). This measure has been used in the literature (see Amirkhanyan 2008; Amirkhanyan et al. 2008).²²

We also use four perceptual measures of access from the (XXXXX) Survey. First, variable *self-reported percent residents on Medicaid* was created:

“Please, specify the percentage of all residents in your nursing home whose care is currently funded by the Medicaid program, Medicare program, or other sources of payment (e.g., out-of-pocket pay or private insurance).
% residents on Medicaid: _____.”

The correlation coefficient between this measure and the “archival” measure is 0.8, which may suggest recall problems or fluctuation of residents on Medicaid. We also used these three variables (with strongly agree (4), agree (3), disagree (2) and strongly disagree (1) categories):

²⁰ Factor analysis suggested using all six items in a single scale was appropriate. Following the Guttman-Kaiser rule, only Factor1 Eigenvalue was above one (2.96), suggesting one factor should be retained. All factors have moderate to high loadings in Factor 1 (for Item1=.75; item2=.70; Item3=.70; Item4=.68; Item5=.65; Item6=.72). The Cronbach's alpha is 0.79. A predicted score generated from on factor loadings was used as a dependent variable.

²¹ As opposed to Medicare, private long-term care insurance or private-pay.

²² It is also similar to the one used by Harrington Meyer (2001), who used Medicaid to private pay ratio in the facility as a measure of access.

1. *Some cannot afford staying here* (Survey item: “Some of our residents have to look for another nursing home because they cannot afford staying here”);
2. *Difficulty serving the uninsured* (Survey item: “Our nursing home has difficulty admitting or serving uninsured clients”);
3. *Difficulty serving clients on Medicaid* (Survey item: “Our nursing home has difficulty admitting and serving residents funded by the Medicaid program”).

Independent Variables: Organizational Management. We created three measures reflecting nursing home administrators’ management strategies based on the (XXXXX) Survey. First, variable *sharing power* reflects the administrator’s propensity to involve other stakeholders in decision-making. It is the average of the three items (with strongly agree (4), agree (3), disagree (2) and strongly disagree (1) response categories):²³

To what extent do you agree or disagree with the following statements?

1. I involve nursing and other non-managerial staff in my nursing home’s decision-making process.
2. Residents’ and families’ feedback and outcomes are taken into consideration when revising policies.
3. Non-manager feedback is taken into consideration when revising policies.

Second, *innovation* reflects a nursing home administrator’s propensity to look for and adopt new ideas or practices. This measure is the average of three items:²⁴

To what extent do you agree or disagree with the following statements?

1. Our nursing home is always among the first to adopt new technology and practices.
2. We continually search for new opportunities to provide services to our community.
3. Our nursing home is always among the first to adopt new ideas and practices.

²³ Correlation coefficients suggest moderate positive associations between three variables. The Cronbach’s alpha is 0.7429, which supports the idea of a single latent factor. In the factor analysis of three items, following the Guttman-Kaiser rule, only Factor1 has the Eigenvalue greater than one (1.98315), suggesting that one factor should be retained. All factors have moderate to high loadings in Factor 1 (factor loadings for Item1=.77; item2=.84; Item3=.83). Independent variable representing this and other management strategies represent averages of items included in the scale.

²⁴ Correlation matrix between three variables suggest moderate to strong positive associations. The Cronbach’s alpha is 0.81, supporting the idea of a single latent factor. Following the Guttman-Kaiser rule, only Factor1 has the Eigenvalue greater than one (2.17731), suggesting that one factor should be retained. All factors have moderate to high loadings in Factor 1 (factor loadings for Item1=.86; item2=.80; Item3=.90).

Third, *managing external influences* reflects an administrator's strategies focusing on external influences. We use the average of the following four items:²⁵

To what extent do you agree or disagree with the following statements?

1. My role is to respond to various events and disturbances in the external environment of our nursing home.
2. I always try to limit the influence of external events on the staff and nurses.
3. I strive to control those factors outside the nursing home that could have an effect on my organization.
4. Our nursing home emphasizes the importance of learning from the experience of others.²⁶

Ownership and Other Independent Variables. Two nominal variables indicate ownership status: nonprofit nursing home and public nursing home (NHC). For-profit ownership is the omitted category in all regressions. The variable *number of certified beds* reflects nursing home's size (NHC). *Number of residents* reflects the number of clients in a nursing home (NHC). To measure staffing, we use *total nurse hours per resident per day* including registered, vocational nurse and nurse aide hours (NHC). *Hospital affiliated home* reflects affiliation with a hospital (1=yes, 0=no) (NHC). *Change of owner* indicates whether a facility changed its owner within 12 months (yes = 1, no= 0) (NHC). We use a proxy variable *years since certification* to measure facility's age (NHC).²⁷ For competition, we use the *Herfindahl index* (Angelelli et al. 2003; Castle 2005): the sum of squared market shares (#beds) for all nursing homes in a county, varying between zero and one (NHC).²⁸ Finally, seven county-level measures were created from the AHRF data. *Population density* per square mile (in 1000s) reflects urbanicity, identified as a

²⁵ The Cronbach's alpha for this scale is 0.59. Following the Guttman-Kaiser rule, only Factor1 has the Eigenvalue greater than one (1.82661), suggesting that one factor should be retained. All factors have moderate to high loadings in Factor 1 (factor loadings for Item1=.59; item2=.67; Item3=.81; Item4=.62).

²⁶ To maximize our sample size, we imputed the mean for the missing values of all items comprising these three management scales. For the three items comprising the "sharing power" scale, percentage of missing cases was 2.38% (item1); 2.38% (item2); and 2.24% (item3). For the three items comprising the "innovation management" scale, percentage of missing cases was 2.38% (item1); 2.38% (item2); and 12.03% (item3). For the four items comprising the "external management" scale, percentage of missing cases was as follows: 3.36% (item1); 3.64% (item2); 3.5% (item3), and 12.4% (item4).

²⁷ This is an imperfect proxy, as some facilities undergo organizational changes associated with a loss and/or more recent reacquisition of Medicare and/or Medicaid certification.

²⁸ This index approaches the value of 1 for the least competitive markets with a dominant provider, and zero – for the most competitive and least concentrated markets, with numerous providers that have similar market shares.

key predictor of quality. We also include *percent in poverty* (below the poverty line), *percent elderly* (65+), and *percent White*. Three variables account for alternative medical providers: *number of home health agencies*, *number of hospices* and *number of hospitals* in the county.

Regression Analysis. We use multiple regression analysis to estimate several “quality” and “access” models. In the general form, the models are as follows:

Quality Model

$$Q_{2013-2012} = \beta_0 + \beta_1 M_{2013-2012} + \beta_2 N_{2011-2010} + \beta_3 P_{2011-2010} + \beta_4 A_{2011-2010} + \beta_5 X_{2011-2010} + e_1$$

Access Model

$$A_{2013-2012} = \delta_0 + \delta_1 M_{2013-2012} + \delta_2 N_{2011-2010} + \delta_3 P_{2011-2010} + \delta_4 Q_{2011-2010} + \delta_5 X_{2011-2010} + e_2$$

where Q = quality, A = access, M =management, N = nonprofit ownership, P = public ownership, and X = controls.

The dependent variables are the most recent survey record as of 01/2014, i.e., 2013 and late 2012 survey cycles. The independent variables pertain to one of the previous survey’s cycles between 2011 and 2010. Since the (XXXXX) Survey was administered in 2012-2013, all management variables are contemporaneous with the dependent variables.²⁹

We use two alternative regression models to examine the *total number of health deficiencies*. First, we use OLS with robust standard errors (to address heteroscedasticity) and state fixed effects (to alleviate interdependency of observations at the state level). Second, we use a Negative Binomial (NB) model with state fixed effects. The dependent variable – *total number of health deficiencies* – is a positive count with a positively skewed Poisson distribution.³⁰ In the second archival quality model the dependent variable, *overall 5-star rating*, is ordinal. We used ordered logit with state fixed effects. For the perceptual quality model

²⁹ In the AHRF, *percent elderly*, *percent in poverty*, *number of home health agencies* and *number of hospices* in all models were for 2011, while *population density*, *number of hospitals* and *percent white* were for 2010.

³⁰ We first ran the Poisson regression and examined the goodness of fit. The Pearson chi-square and deviance were greater than one and indicated over-dispersion which violates the assumption of equality of the mean and the variance of the dependent variable imposed by the Poisson model. NB model accommodates overdispersion by including a random term reflecting unexplained between-subject differences (Gardner, Mulvey, and Shaw 1995).

(*perceived nursing home quality*), we use OLS with robust standard errors and state fixed effects. The individual factor scores used as a dependent variable reflect individual nursing homes' placement on an underlying factor of "perceived quality." In the archival access model (*%residents on Medicaid*), we use OLS with robust standard errors and state fixed effects. We also ran four *perceptual* access models. OLS is used for *self-reported percent on Medicaid*. For the remaining three perceptual measures of access (*some cannot afford staying here, difficulty serving the uninsured and difficulty serving clients on Medicaid*), we use ordered logit.

FINDINGS

Summary statistics for all variables are in Table 1. Table 2 presents the quality models. We first examine the findings on archival measures: the *total number of health deficiencies* and the *5-star rating*. *Innovation management* – perceived and self-reported search for and adoption of new technologies, ideas, and practices – is associated with a significant reduction in the number of deficiencies in both models. In the fixed effects model, the slope is -1.26. It is also associated with an increase in the *overall 5-star rating*. With a one-point increase in innovation levels, a nursing home's ordered log-odds of being in a higher five-star rating category would increase by 0.31, while keeping other variables constant. External management and sharing power are not significant. Additionally, public and nonprofit nursing homes perform significantly better than their for-profit counterparts. They have fewer *health deficiencies* and higher *5-star rating*. In the fixed effects models, public and nonprofit homes have fewer violations than for-profit facilities by 1.8 and 1.7, respectively (sig. <0.001). In the nursing home context, these differences are practically important: a single violation may reflect a breach of a regulatory code related to patient quality of life or care, triggering repeat inspections, fines, and lawsuits.

Consistent with the past research, larger nursing homes have more deficiencies and lower star ratings. Meanwhile, occupancy is associated with fewer deficiencies. As the percentage of clients on Medicaid increases, the number of deficiencies increases as well, while the *overall 5-star rating* significantly decreases (but the magnitude is negligible). Finally, higher population density is associated with fewer health deficiencies and higher star rating.

[Tables 1 and 2 about here]

Our secondary goal was to compare the findings across archival and perceptual measures of performance. The perceptual model is only partially consistent with the archival findings. *All* management variables are associated with higher perceived quality. This enhanced estimation of management effect likely suggests common source bias. Public (but not nonprofit) administrators had significantly more positive perceptions of their homes' performance than for-profit administrators. Our findings related to size, occupancy, density, and percentage of Medicaid residents mirror the archival models. Two variables are only significant in the perceptual model: perceived quality declines with organizational age and in counties with lower poverty rate.

The findings on access are presented in Table 3. In the archival model, two management variables are significant: with 90% confidence, as *innovation* increases, *percent residents on Medicaid* decreases by 3 percentage points. Meanwhile, nursing homes where administrators report *sharing power* (i.e., taking into consideration others' feedback) have a higher percentage of residents on Medicaid (the magnitude is 5.1). Nonprofit nursing homes have a significantly lower percentage of residents on Medicaid (with a sizeable 10 percentage-point magnitude) compared to for-profit homes. Additionally, as facility age increases, the Medicaid percentage goes up. Staffing is significantly lower in facilities with more Medicaid residents. Finally, as the poverty rate and market competition increase, so does the *percent residents on Medicaid*.

[Table 3 about here]

Our findings in the perceptual access models are mixed. Respondents in the (XXXXX) Survey were asked to report the current percentage of facility residents on Medicaid. The findings are similar to those in the archival model with two exceptions: management strategies as well as competition are not significant. The remaining three perceptual models of access are less informative.³¹ Two models suggest that using power-sharing strategies are associated with limited access for the low-income clients. Also, administrators in public and nonprofit nursing homes are significantly less likely to report that their clients cannot afford staying in their facilities or that their homes have difficulty serving the uninsured and Medicaid-funded clients.

DISCUSSION

This study examines the effect of three management strategies – innovation, shared decision-making, and management of external influences – and other organizational and environmental factors on numerous measures of service quality and access in U.S. nursing homes. Innovation management is associated with significantly fewer health violations assigned by state inspectors and higher facilities' star ratings. Further, innovative management strategies also appear to be positively related to a nursing home's ability to fill their beds with non-Medicaid clients, thus limiting access of low-income or impoverished clients. These findings are tied to the nature of the nursing home industry. Innovation management reflects the managers' propensity to adopt new facility designs, search for new service opportunities, and adopt new ideas, care practices, and technologies. These practices can contribute to the formalization of cutting-edge professional practices that help achieve greater efficiency, improve the quality of care, and reduce the likelihood of violations. These findings are supported by the health care literature on the use of new technologies and their effect on overall organizational performance

³¹ To improve the fit of these models, we ran simple ordered logit, without controlling for state fixed effects.

(Baril et al. 2014). Furthermore, in competitive markets, facilities compete for non-Medicaid clients, whose cost-to-reimbursement ratios are attractive for providers. The focus on innovation may result in a competitive advantage, enhancing the facility's reputation, and attracting healthier, more informed and affluent clients.

Shared decision-making and external management are not associated with service quality. These findings also reflect the context of nursing home care. Taking the time to inform and engage with internal and external stakeholders in decision-making may be viewed as time-consuming and inconsistent with a management culture of "putting out fires." A recent nursing home study indicates that top managers spend most of their time addressing facilities' short-term, daily operational needs (Castle et al. 2009). Their behavior tends to be reactive: with short-term, rather than long-term agendas. Notably, more centralized (not shared) decision-making is associated with fewer Medicaid clients. The literature is mixed on the effect of distributed leadership in nursing homes (Deutschman 2005; Fitzgerald et al. 2013; Rondeau and Wagar 2001; Tomlinson 2012). Our findings echo Deutschman's (2005) that managers prioritize other factors (e.g., regulations or efficiency) over staff engagement and empowerment. Greater power sharing in homes with more Medicaid clients may suggest that in uncertain, cash-constrained environments, administrators tend to adopt relationship-oriented styles. With the modest significance levels in archival models, more research is needed to understand this relationship.

Our findings on ownership are particularly interesting. After controlling for management, ownership in our models may be capturing management practices related to resource allocation and organizational priorities. In the archival models, nonprofit and public ownership is associated with fewer violations and higher star ratings. Nonprofit homes also serve fewer Medicaid clients. These findings are consistent with the theories of nursing home ownership and

performance. Informational asymmetries and limited Medicaid reimbursements determine what appears to be a zero-sum game between quality and access in the private sector. These findings are also consistent with the evidence in the broader organizational management literature suggesting that organizations often pursue conflicting priorities. The for-profit homes are incentivized to divert revenues away from quality, while serving older and more disabled Medicaid-funded clients. Meanwhile, the nonprofit homes, a quarter of the industry, cultivate quality by targeting, marketing to, and admitting the more affluent private-pay, privately-insured, or Medicare clients. The latter reflects nonprofits' tendency towards philanthropic individualism and particularism – a propensity to focus on specific target groups, and seek to satisfy their needs irrespective of efficiency considerations (Salamon 2002; Steinberg 2006). Government providers appear to prioritize both dimensions of performance. Importantly, past service to the Medicaid clients is associated with the future prevalence of health deficiencies as well as the star ratings, suggesting that lower revenues undermine future quality.

We supplement our analysis with perceptual measures. In the quality models, all management variables are significant and positive. These findings likely reflect common source bias – the administrators' propensity to favorably report on their practices and successes (Boyne et al. 2006; Meier and O'Toole 2013a). The bias is less likely to affect the access measures, since the difficulty serving the uninsured is unlikely to be thought of as a measure of success by the administrators, who are often financially rewarded for Medicare admissions. Despite some consistency across the archival and perceptual models, some counterintuitive findings in the perceptual models, such as higher perceived quality in less affluent areas, support the idea that these models may be falsely identifying associations (Meier and O'Toole 2013a).

Additional discrepancies related to the effect of ownership on performance are notable, consistent with past research (Amirkhanyan et al. 2014; Shingler et al. 2008). Theoretically, perceptual measures should correlate with the archival indicators that managers carefully track. Yet the nonprofits' subjective assessments of quality are not significantly different from those in the for-profit sector. Meanwhile, public-sector administrators are in fact reporting higher perceived quality than those in the for-profit facilities. Similar differences are present for access to care. While aware of the extent of service to Medicaid recipients, public and nonprofit administrators' responses to the more general questions about access diverge from these findings. Perhaps, reflective of their social missions, nonprofits report providing better access to the uninsured and Medicaid clients compared to for-profits. Public-sector administrators may perceive their homes as a "safety net" in comparison to their for-profit counterparts, despite the fact that their Medicaid admissions are in fact not different from those in the for-profit sector. Even though our measures are fairly specific and meet the general conditions for comparability with the archival measures, we observe discrepancies in terms of the relationship between various factors and the archival and perceptual measures. While the formal indicators are widely available, they do not directly inform the managers' perceptions of quality and access. Consistent with the literature on perceptual measures of performance, our findings suggest that relying exclusively on the *internal* stakeholders' assessments— in this context or in the broader organizational management literature – is insufficient to understand the scope and the sources of improvements.

Some additional findings merit attention to help understand the sources of improvement in organizational performance. Consistent with the argument that resources are the most likely sources of performance improvements, having more non-Medicaid clients (and hence, higher

revenues) is associated with fewer violations and higher star ratings. The effect of population density suggests that higher care quality is harder to achieve in less populated areas.

Additionally, consistent with the past nursing home care literature, larger nursing homes provide lower quality of care. Smaller nursing homes may be more effective at creating unique environments and personalizing care for their residents (Amirkhanyan 2008).

We reflect upon our use of hybrid data, its merits and limits. The key advantage, as noted earlier, is in connecting “the black box” of management and the richness of the internal organizational context to the performance data generated in a standardized fashion by independent stakeholders (Boyne et al. 2006). The (XXXXX) Survey was designed and administered after a carefully considering the archival measures of the NHC data, resulting in perceptual data tailored to the archival data.³² Clearly, primary data collection may not always be feasible or may present selection challenges due to lower response rates. Merging two secondary data sets into a hybrid data set, in turn, may present its own unique challenges.

We note several limitations of this study. Our findings suggest that the policy context is key in understanding what strategies are related to performance. This study is conducted in a market with high asset specificity, dependent clientele, extensive government subsidies and regulation, and relatively low service measurability. The use of formal long-term care is higher in countries and communities with a higher employment rate, higher job-related mobility, better retirement benefits, and, therefore, higher prevalence of nuclear families. Our findings on

³² The [XXX] Nursing Home Administrator Survey (NHAS), administered by the authors of this study, includes perceptual measures of performance developed to (1) be specific in referring to various aspects of performance, and (2) generally reflect the archival measures included in the NHC data to allow us to compare results across measures. Thus, the NHC data set includes information on the percentage of residents receiving Medicaid. In the NHAS, also asked respondents for the same information. (Additionally, we asked three alternative questions on access). The regulatory violations in the NHC data are based on various mandates pertaining, broadly, to quality of care, resident behavior and facility practices, resident rights, physical environment, and others. The subjective nursing home performance scale in the NHAS includes several (albeit, limited, by virtue of survey length limitations) questions touching upon several key categories of care quality, facility condition, residents’ rights, and others.

management, thus, may be more generalizable to similar markets³³ and less generalizable to other policy fields.

Furthermore, while our use of hybrid data helps avoid common source bias by using archival data along with perceptual managerial measures, the latter measures may be subject to positivity and social desirability bias. The online/mail-in character of the XXXX Survey may help minimize this concern. Additionally, as noted earlier, our sample is more likely to include better performing facilities, and hence the effect of management that we observe may be more pronounced in those homes. Finally, while we control for a wide range of factors typically included in the analysis of nursing home quality, we cannot exclude the possibility of omitted variable bias. Thus, we lack data on financial performance of nursing homes which would present additional interesting directions for this study. (The percentage of residents funded by Medicaid we include here could serve as an indirect measure of facility revenues.)

Finally, we note two directions for further research. Boyne (2003) finds as an important source of public sector improvement – government regulation. While our current paper uses two products of the regulatory process – deficiencies and star ratings – we do not directly consider the *process* of regulation and the administrators’ relevant experiences and perceptions. The latter is extremely important in the heavily regulated U.S. nursing home context. Understanding how government regulation is perceived by public, nonprofit, and for-profit administrators and exploring the influence of these experiences and perceptions on the facilities’ performance may

³³ These may include fields such as substance abuse, mental health, or developmental disabilities services, family-centered social services, child care, or home health care. Nonetheless, important differences across these fields should not be disregarded. None of these services require the level of technological and scientific sophistication prevalent in nursing homes. Their financing and regulation, mostly done through state and local government contracts and contract monitoring, is also quite different from the formal state inspection, licensure and reimbursement processes in nursing home care.

inform our understanding of how government quality assurance and assessment influence service quality.

Furthermore, our perceptual measures of quality come from a single source – the nursing home administrators. Subjective assessments of organizational performance can come from numerous external and internal constituencies that are likely to have different needs and perspectives of the value of public services (Connolly, Conlon, and Deutsch, 1980). Thus, a more comprehensive analysis of performance would incorporate other assessments, for instance those coming from the organizational clients. While we do not have data on client satisfaction, some NHC deficiencies are associated with client complaints. As a next step, we plan on exploring complaint-based violations and comparing them with those based on the standard facility surveys conducted by state inspectors.

TABLES

Table 1. Dependent and Independent Variables. Descriptive Statistics.

Dependent Variables	Mean	St.D.	Min	Max	Obs
Archival Quality Measures					
Total number of health deficiencies (NHC)	5.87	5.04	0	31	713
Overall 5-star rating* (NHC)	3.65	1.24	1	5	682

Appendix A.

Comparison of All Operating US Nursing Homes to Our Sample.

	Population (2013-2012 wave)	Sample (2013-2012 wave)
Ownership	Percent residents on Medicaid (means)	
For-profit	63.23	62.44
Nonprofit	49.03	50.34
Public	62.10	61.96
	Number of certified beds (means)	
For-profit	109.56	110.52
Nonprofit	94.25	94.67
Public	114.96	105.39
	Number of residents (means)	
For-profit	89.17	91.50
Nonprofit	81.17	83.21
Public	94.98	90.01
	Total nurse hours per resident per day (means)	
For-profit	3.93	3.95
Nonprofit	4.53	4.37
Public	4.49	4.49
	Hospital affiliation (proportion "affiliated")	
For-profit	0.011	0.009
Nonprofit	0.145	0.124
Public	0.262	0.196
	Number of health deficiencies (means)	
For-profit	7.49	6.74
Nonprofit	5.36	5.03
Public	6.44	6.01
	5-star rating (means)	
For-profit	3.19	3.19
Nonprofit	3.79	3.97
Public	3.58	3.73
