Carriage of the New Delhi metallo-β-lactamase variant 1 (NDM-1) enables drug resistance to move between communities and hospitals. In Bangladesh, we found the blaNDM-1 gene in 62% of environmental waters and in fermentative and nonfermentative gram-negative bacteria. Escherichia coli sequence type (ST) 101 was most commonly found, reflecting a common global relationship between ST101 and NDM-1.

Carbapenemases, bacterial enzymes that typically inactivate most of the β-lactam class of antimicrobial drugs, have emerged rapidly over the past decade (1). These resistance mechanisms are often accompanied by other resistance alleles, and together they can confer extensive drug resistance, leaving minimal treatment options (2). The New Delhi metallo-β-lactamase variant 1 (NDM-1), a chimera formed by the fusion of 2 resistance genes, is unique among the carbapenemases (3). Since its description in 2009, NDM-1 has spread rapidly to many countries worldwide and appears to be endemic in South Asia (1,4,5).

A study of the environment in New Delhi, India, showed that ≈30% of surface waters and sewage was contaminated with NDM-1; the enzyme was also detected in drinking water and food through inadequate sewage treatment (4-7). In addition, high rates of NDM-1 gut carriage have been found in the community and in hospitals in Pakistan (7). High rates of gut carriage can lead to contamination of drinking water and food through inadequate sewage treatment. Furthermore, gut carriage of NDM-1–encoding Escherichia coli can lead to common community-acquired infections (e.g., urinary tract infections), which often require hospitalization (8) and enable resistance mechanisms to move between community and hospital sectors. Indirect studies in 2009 and 2010 showed that NDM-1 was not present in the Bangladesh environment (9,10). To determine whether NDM-1 is now present in Bangladesh, we surveyed the environmental waters of Dhaka.

The Study
During October 19–27, 2012, we collected environmental water/sewage samples from 7 regions (58 sites) in Dhaka, Bangladesh (Figure 1). Control samples were from the United Kingdom. Each sample was investigated for bacterial growth on UTI brilliance agar plates (Thermo Fisher Scientific, Basingstoke, UK) containing vancomycin (30 mg/L) plus meropenem (0.5 mg/L). The species of individual colonies of different colors and morphologies were determined by using matrix-assisted laser desorption/ionization time-of-flight mass spectrometry. Bacteria were genetically characterized by blaNDM-specific PCR. Genetic location of the blaNDM-1 gene was determined by probing S1 nuclease pulsed-field gels. A subset of isolates of each species was further investigated for MICs of relevant antimicrobial drugs. All E. coli isolates were genotypically determined to determine multilocus sequence typing group; examples of each group were characterized for additional relevant resistance mechanisms. Details are provided in the online Technical Appendix (http://wwwnc.cdc.gov/EID/article/21/6/14-1578-Techapp1.pdf).

The carbapenemase and extended-spectrum β-lactamase genes blaNDM-1 and blaCTX-M-15 were detected by PCR in 36 (62%) and 41 (71%), respectively, of the 58 water samples. Both genes were found at all 7 sample region sites in Dhaka. Gene blaCTX-M-15, but not blaNDM-1, was detected in sewage samples from the United Kingdom; neither was detected in UK water samples from the River Thames.

We identified 226 gram-negative NDM-1–producing isolates to the species level (Figure 1; online Technical Appendix Table 1); 15 isolates harboring blaNDM-1 could not be identified and were not investigated further. The most widely disseminated bacteria in samples from Dhaka were pseudomonads (6/7 regions) and Klebsiella pneumoniae (4/7 regions). Nine different species of Pseudomonas spp. and 5 Acinetobacter spp., mostly belonging to nonpathogenic genic strains, were among the nonfermentative bacteria (online Technical Appendix Table 1). Carbapenem resistance in the Pseudomonas spp. isolates was unstable; all strains lost the blaNDM-1 gene after 2 days’ growth or when frozen for storage.

With the exception of 4 isolates, all bacterial isolates contained the original blaNDM-1 allele; 3 E. coli sequence type (ST) 101 isolates carried the blaNDM-1 variant, and 1 ST648 isolate carried the blaNDM-4 variant (online Technical Appendix Table 2). S1 nuclease pulsed-field gel electrophoresis combined with blaNDM-1 probes detected blaNDM-1 on plasmids of limited size diversity in E. coli (ST101, 160 kb; ST405, 100 kb; ST648, 150 kb); however, other species included blaNDM-1–positive plasmids in

a wide diversity of sizes (30 kb–450 kb); some of these species had multiple positive plasmids, and \textit{bla}_{\text{NDM-1}} was also found on the chromosome (online Technical Appendix Table 1 and Figure 1).

The \textit{E. coli} isolates were further analyzed by PCR to identify additional resistance mechanisms often associated with \textit{bla}_{\text{NDM-1}} (Table). \textit{bla}_{\text{CTX-M-15}} and 16s ribosomal methylase genes (\textit{armA} or \textit{rmtB}) were associated with most \textit{E. coli} strains, which explains the extensively drug-resistant phenotype of the \textit{E. coli} isolates (online Technical Appendix Table 3). Plasmids of plasmid incompatibility groups \textit{incFII} (ST101, ST405, ST648) and \textit{incX} (ST405, ST648) were also closely associated with \textit{E. coli} strains (Table). \textit{E. coli} harboring \textit{bla}_{\text{NDM-1}} were isolated from 10 sampling sites (Figure 1; online Technical Appendix Table 1). The \textit{E. coli} isolates belonged to 3 different multilocus sequence typing groups: ST101 (phylogroup B1, 20/53 samples); ST405 (phylogroup D, 5/53 samples); and ST648 (phylogroup D, 28/53 samples) (online Technical Appendix Table 2). ST101, which was found in samples from 6 (10.3%) of the 58 sites, was the most prevalent NDM-1–encoding \textit{E. coli} genotype. ST648 represented an intermediate prevalence (5/58 [8.6%] sites), and ST405 was the least prevalent (1/58 [1.7%] sites) (online Technical Appendix Tables 1, 2).

**Conclusions**

Our findings indicate that NDM-1 is widespread in the Dhaka environment. We detected 241 NDM-1–encoding bacterial isolates; they were found in all 7 sampled regions and at 36 (62%) of the 58 sampling sites. This high level of environmental \textit{bla}_{\text{NDM-1}} contamination is of concern, especially because drinking water in Bangladesh usually carries high levels of sewage-derived bacteria (11). It is therefore likely that \textit{bla}_{\text{NDM-1}} carriage rates will rise rapidly. Future environmental studies could provide...
indicators of epidemics of emerging resistant bacteria before they are realized in hospitals.

Despite the widespread presence of NDM-1 in Dhaka, it appears that this carbapenemase has recently emerged in the Bangladesh environment. Studies in northern Bangladesh did not find NDM-1 in wild ducks and poultry in 2009 (9) or in crow and gull feces in 2010 (10). Similarly, NDM-1 was not detected in drinking water in Dhaka during 2008–2009 (11) even though all samples had high levels of fecal and blaCTX-M-15 contamination. Furthermore, a study of 1,879 clinical E. coli and Shigella spp. isolates collected during 2009–2010 in Bangladesh did not detect blaNDM-1 (12). The first known clinical isolates date from 2008 (12), and the first evidence of human gut carriage of blaNDM-1 was found in samples collected in Dhaka (13) a month before our study.

Because E. coli is the leading cause of human urinary tract infections, bloodstream infections, and neonatal meningitis, the ability of NDM-1 to give this bacterium clinical resistance to carbapenems is of concern (14). E. coli is also universally carried in the human gut. Therefore, we focused on this species because it is likely to be the greatest threat to human health. E. coli encoding NDM-1 were found in 3 of the 7 sampled regions, and genotyping showed they belonged to only 3 STs: ST648, ST101, and ST405. These same 3 E. coli genotypes are

Figure 2. Sites where New-Delhi metallo-β-lactamase variant 1 (NDM-1)–encoding Escherichia coli sequence type (ST) 101 isolates have been detected worldwide. Stars indicate countries where NDM-encoding E. coli ST101 has been detected: Australia, Bangladesh, Belgium, Bulgaria, China, Canada, Denmark, France, Germany, India, Korea, New Zealand, Pakistan, the United Kingdom, and the United States.
responsible for 80% of clinical NDM-1–encoding E. coli isolates in the United Kingdom (J5). Furthermore, ST101 is the most common E. coli genotype in the Bangladesh environment (10.3% prevalence) and in clinical isolates from the United Kingdom (50%). Results of a literature search for NDM-1–encoding E. coli belonging to ST101 showed that this genotype has been detected in 15 nations (Figure 2). Thus, E. coli ST101 appears to be a successful global genotype that is often associated with NDM-1. This association with a single global genotype is analogous to the association between E. coli ST131 and the cephalosporinase CTX-M-15. Because of the critical nature of extensively drug-resistant bacteria, we are investigating the underlying factors responsible for the success of these particular antimicrobial drug–resistant strains.
