Capsule Summary

Under inflammatory conditions where IL-1 β is present, iT_H2 cells exacerbate allergic responses critical in orchestrating asthmatic lung immunopathology, suggesting IL-1 signalling on CD4 as a critical target in allergic asthma.

Interleukin-1 beta enhances inflammatory Th2 differentiation

To the Editor:

Type 2 immune responses are critically dependent on the canonical cytokines, IL-4 and IL-13, two related cytokines that both utilize IL-4R α for signalling. These mediators have both overlapping and independent functions with IL-4 involved in the initiation of Th2 differentiation and immunoglobulin class switching and IL-13 in Th2 inflammatory responses (iTh2). Hallmarks of infections associated with type 2 immune responses are the infiltration of affected tissues by helper T cells, eosinophils and basophils, activation of macrophages, smooth muscle and tissue remodelling, and elevated levels of IgE.¹

We have previously reported that IL-1 β strikingly enhances CD4 T cell survival, antigen-driven expansion, differentiation and cytokine *in vivo* production.^{2,3} To investigate the impact of IL-1 β on Th2 differentiation in greater detail, pigeon cytochrome c (PCC)-specific 5C.C7 CD4 T cells were cultured under Th2 polarizing conditions. Anti-IL-1 α/β or IL-1Ra (anakinra) were included in control cultures to generate Th2 cells in the absence of IL-1 signalling for comparison to those exposed to IL-1 β . IL-4 production was reduced in Th2 cells primed with IL-1 β compared to the anti-IL-1 and anakinra groups; by contrast, IL-13 production was dramatically increased among cells primed with IL-1 β (Fig. 1A). IL-1R1 was also detected on over 50% of Th2 cells at 72h and maintained at higher levels on Th2 IL-1 β cells as compared to anti-IL-1 treated Th2 cells at 96h (Fig. 1B). To assess the contribution of IL-1R expression to this pattern of cytokine production, T cells were cultured for 2 days with anti-IL-1 α/β or IL-1 β , sorted for IL-1R1, and then placed back in their original culture conditions for 2 days before analysis (Fig. 1C). The data suggest that cells acquiring expression of IL-1R during early Th2 differentiation are especially susceptible to adopting a dominant IL-13 producing phenotype when exposed to IL-1 at this time. IL-5 expression showed similar enhancement in the IL-1R+, IL-1 group (Fig. 1D). Similar results were obtained using wild type and other TCR-Tg CD4+T cells suggesting that the phenomenon was not restricted to a single antigen or TcR (data not shown).

To assess their phenotypic stability, both Th2 groups differentiated *in vitro* were sorted for IL-1R1 and either reprimed *in vitro* under neutral, Th1 or Th2 conditions or transferred *in vivo* into mice rechallenged intranasally (IN): Fig. E1A and B show that independently of the secondary condition, the original phenotypes were stably maintained.

Myd88 and NF- κ B are involved in the IL-1R1 canonical signalling pathway. To analyze their contributions in our system, we cultured OT-II, OT-II IL-1R1^{-/-} or OT-II Myd88^{-/-} T cells together with wild type APCs. Fig. E1C shows that IL-1 β -dependent enhancement of IL-13 production required both IL-1R1 and Myd88 expression on the responding CD4 T cells but not on APCs (data not shown). To test the contribution of NF- κ B, Th2 cells \pm anti-IL-1 α/β were treated with an NF- κ B activation inhibitor. No effect was observed with anti-IL-1, but IL-13 expression was significantly diminished and IL-4 production enhanced in the IL-1 β group indicating a contribution of IL-1R/NF- κ B pathway to the cytokine production phenotype we observe after IL-1 β exposure (Fig. E1D).

Chromatin immunoprecipitation analysis of Il13, Il4 and Ifn γ promoter regions was carried out on both Th2 groups using antibody to the activating AcH3K27 modification (Fig. E2A).⁴ Il13 HSII and Il13 HSIII, but not Il13 or Il4 HSIII showed a clear enhanced immunoprecipitation in the “IL-1 β , IL-1R+” group. Thus, Th2 priming in the presence of IL-1 β causes the promoter and second intron of Il13 to become more transcriptionally active.

Microarray (not shown) and RT-PCR analysis of both Th2 groups showed that Pth, IL-13, IL-5, Ccl17, Timd2, Slc15a3, Slc2a6 and Nts were more highly expressed in the “IL-1 β , IL-1R+” group and IL-4, IL-10 and Myo6 were more highly expressed in the “anti-IL-1, IL-1R-” group. Parathyroid hormone (Pth) showed the greatest enhancement in the “IL-1 β IL-1R+” group. Its expression has previously been reported in activated Th2 cells but not in Th1 cells (Fig. E2B).⁵ We confirmed PTH secretion by ELISA and measured biologically active PTH via cAMP functional assay (Fig. E2C, D).

Th2 differentiation is central to cell recruitment, induction of inflammation and mucus production in the lungs.⁶ Using PCC-specific 5C.C7 CD4+T cells, lymphocytes from the anti-IL-1 treated and the IL-1 β exposed groups were sorted for IL-1R1, adoptively transferred into wild type mice and

the mice challenged IN with antigen + anakinra only - to avoid any potential secondary effect of endogenous IL-1 β (Fig. 2A). The number of eosinophils in the bronchoalveolar lavage (BAL) and in the lungs were significantly greater in mice that received IL-1R+cells primed with IL-1 β . These differences were maintained when the mice were challenged 13 weeks after transfer (Fig. 2B, D). PAS staining of lung sections shows greater peribronchial infiltration of inflammatory cells, goblet cells metaplasia and striking enhancement of mucus production (magenta) in the “IL-1 β , IL-1R+” group with an average histopathology score significantly higher than the controls (Fig. 2C, E, F).

To examine the possible role of IL-1 β during an *in vivo* house dust mite Th2 allergic response, wild type mice were sensitized IN with HDM + anakinra or IL-1 β , and rechallenged 7 days later for 5 consecutive days (Fig. 2G).⁷ IL-13 expression by CD44^{hi} effector CD4+ T cells in the lung and in the BAL was dramatically increased when HDM priming was accompanied by IL-1 β (Fig. 2H). In this model, IL-4 production was also slightly enhanced. Additionally, as anticipated from the increased IL-13 production, the number of infiltrating eosinophils was increased in the BAL of the HDM + IL-1 β group (Fig. 2I). To exclude possible IL-1 enhancement of IL-17 priming, ROR γ t^{-/-} mice were used⁸: histological analysis revealed striking peribronchial inflammatory cell infiltrates, an increase of mucus production (magenta) and goblet cell metaplasia in IL-1 β -treated mice and an average score of inflammation higher compared to the anakinra control (Fig. 2J-L). These results indicate that IL-1 β present during *in vivo* Th2 priming causes increased allergic effector responses. Subsequently, IL-1 β blockade maintains low levels of IL-13, limiting the infiltration and mucus production.

Based on these findings we propose that natural Th2 priming that occurs in inflammatory settings where IL-1 β is present gives rise to iT_H2 cells that are specialized to induce allergic inflammatory responses, while those primed in its absence are more important as regulatory cells, i.e. amplifiers of Th2 cells and antibody response by B cells. Signalling through the IL-1 receptor during priming is the major determinant of the distinctive phenotypes of these two types of Th2 cells and translates into differences in *in vivo* inflammatory responses.

Material & Methods

Mice

C57BL/6 and B6 ROR γ t^{-/-} mice were obtained from Jackson Laboratory, C57BL/6 OT-II Rag2^{-/-} CD45.1, B6 OT-II Rag2^{-/-} IL-1R1^{-/-}, B10.A, B10.A 5C.C7 Rag2^{-/-} CD45.1, BALB/c DO11.10 Rag2^{-/-} CD45.1 and BALB/c mice were obtained from Taconic Farms Germantown, NY. B6 OTII-Myd88^{-/-} mice were obtained from Ryoji Yagi. All mice were housed under specific pathogen-free animal conditions at the National Institute of Allergy and Infectious Diseases (NIAID), and used between 6 and 12 weeks of age in accordance with guidelines provided by the Institutional Animal Care and Use Committee of the NIAID.

***In vitro* T cell differentiation**

T cell differentiation was performed as previously described⁹. Briefly, naïve CD4 T cells were cultured with irradiated T-depleted splenocytes or DCs in presence of their cognate peptide with combinations of antibodies and cytokines for 4-5 days: IL-2, IL-12 and anti-IL-4 for Th1 differentiation; IL-2, IL-4, anti-IFN- γ and anti-IL-12 for Th2 and anti-IL-4, anti-IFN- γ , anti-IL-12, IL-6, TGF β , and IL-21 for Th17 differentiation. Th2 cells were rested in IL-2 supplemented medium prior *in vivo* transfer when required. When specified a combination of 1 μ g/ml anti-IL-1 α + 1 μ g/ml anti-IL-1 β (R&D Systems) or IL-1 β 10ng/ml (Peprotech) was used.

In some experiments, 6-Amino-4-(4-phenoxyphenylethylamino) quinazoline (Calbiochem), a NF- κ B activation inhibitor was also added. To generate IL-1R⁻ and IL-1R⁺ cells, Th2 cells primed for 2 days in the presence of anti-IL-1 α/β or IL-1 β were washed and resuspended with fresh Th2 medium to remove IL-1 β bound to the IL-1R. 14h later, activated TCR-Tg CD4 T cells were harvested, sorted for IL-1R1 expression amplified with PE FASER kit (Miltenyi) and put back in the original culture medium.

Secondary culture

Th2 cells primed for 5 days in the presence of anti-IL-1 α / β or IL-1 β were reprimed under neutral (IL-2 + 1 μ M PCC with T-depleted irradiated APC), Th1, or Th2 conditions.

Cell transfer and *in vivo* immunization

0.5 to 1 million cells were transferred intravenously and mice were immunized intranasally with 100 μ g ovalbumin or pigeon cytochrome c (Sigma) + 25 μ g lipopolysaccharide (InVivogen). For cytokine instillation, mice were given 1 μ g of recombinant IL-1 β (Peprotech) or 500 μ g IL-1Ra (anakinra, Kineret) intranasally. For induction of allergic asthma, mice were sensitized intranasally with 1 μ g HDM + IL-1 β or anakinra, and rechallenged with 100 μ g HDM + IL-1 β or anakinra for 5 consecutive days 6 days.

Isolation of Lung cells

Lungs were extensively perfused with PBS before being harvested. Lungs were minced with gentleMACS dissociator (Miltenyi Biotec) and digested in LiberaseTM with DNase I (Invitrogen) for 30 minutes at 37°C. The digested tissue was processed on a 40 μ m cell strainer (BD Biosciences), and a single cell suspension was enriched on a 40/60% Percoll gradient centrifugation (GE Healthcare). Broncho alveolar fluid was collected by 5 consecutive washes with PBS+BSA.

Flow Cytometry

Lymph nodes, BAL, spleen and lungs were harvested and single-cell suspensions were prepared. For intracellular staining, cells were stimulated with 1 μ M ionomycin and 10ng/ml PMA for 4-6h and 5 μ M of monensin. Cells were stained with live/dead (Invitrogen), CD4 (RM4.5), CD44 (IM7), CD45.1 (A20), CD45.2 (104), IL-2 (JES6-5H4), IL-4 (11B11), IL-5 (TRFK5), IL-17A (TC11-18H10), IFN- γ (XMG1.2) (BD Bioscience), IL-13 (eBio13A) (eBioscience) antibodies. IL-1R1 (JAMA 174) antibody was purchased from BioLegend, and stained using Faser Kit-PE amplification system (Miltenyi). Data were collected with BDLSRII and analyzed with FlowJo (TreeStar).

Immunohistochemistry and Histopathology

Lung lobes were perfused and immersed in 5% Formalin. Samples were prepared and stained with periodic acid schiff (HistoServe, Germantown, MD; American Histolab, Gaithersburg, MD). Images were acquired using a Leica Episcopes inverted microscope, and processed with Leica LASX software. Siglec-F+ CD11b+ CD11c- expressions were used to identify eosinophils.

Histopathologic scoring system was developed as follows: (0) normal lungs; (1) minor perivascular inflammation around large blood vessels; (2) moderate perivascular and peribronchial inflammation, minimal evidence of goblet cell hyperplasia; (3) increased perivascular and peribronchial inflammation with increased goblet cell hyperplasia beginning in smaller airways; (4) severe formation of perivascular, peribronchial, and interstitial inflammation as well as goblet cell hyperplasia in small and large airways. Grading was performed blinded on unidentified sections.

PTH ELISA

Th1, Th2, Th17, iTreg CD4 T cells primed for 4 days were stimulated with plate bound anti-CD3 (10µg/ml)/ anti-CD28 (10µg/ml). Supernatants were collected 24h later and tested for PTH production by ELISA kit according to manufacturer's recommendation (Immutopics).

cAMP fluorescence resonance energy transfer (FRET) assay

Th1 or Th2 supernatants were mixed with serum-free DMEM containing IBMX and Ro 20-1724 (Sigma, MO). hPTH1R-transfected HEK293T cells were treated with 30µl of this mix at 37C for 1h. cAMP-d2 and cAMP-kryptate were added for 1h. cAMP was measured using FRET at 665nm and 620nm (cisbio, MA).

Chromatin immunoprecipitation

Chromatin immunoprecipitation was performed as previously described¹⁰. In brief, cells were extensively washed with 0.5% BSA/PBS and then resuspended in digestion buffer (Roche). Cells were incubated with 5U of Micrococcal Nuclease (MNase, New England BioLabs) and sonicated to break chromatin to about 200-500bp. The chromatin preparation was dialyzed against RIPA buffer, incubated with anti-acetylated histone 3 H3K27 or control IgG (Abcam), and then

precipitated with Dynabeads protein A beads (Life Technologies). The immunoprecipitated DNA was purified and quantified using real-time PCR with SYBR® Green reagents (ABI).

Primers Il13 HSI: 5'-GCC-CCT-CAA-GAC-AAG-CAG-AA-3' and 5'-ATC-GAC-CCC-ATC-TCC-CGT-TA-3'. Il13 HSII: 5'-CCC-CTG-GTC-TCT-GCT-TTG-TT-3' and 5'-CTG-GAA-ACC-CTG-TCC-CAG-AC-3'. Il13 HSIII: 5'-GCC-TAG-AAT-GTC-GGG-GCT-TT-3' and 5'-GTA-GCC-TAG-GCC-AGC-CAA-AA-3'. Ifny promoter: 5'-CGA-GGA-GCC-TTC-GAT-CAG-GT-3' and 5'-GGT-CAG-CCG-ATG-GCA-GCT-A-3'.

Microarray and Real-time PCR

For microarray analysis, RNA was prepared from Th2 anti-IL-1 α / β , IL-1R- and Th2 IL-1 β , IL-1R+ cells using the Qiagen RNeasy Mini kit. Total RNA was sent to microarray research facility at NIAID Research Technologies Branch for hybridization using the Illumina BeadChip platform.

For RT-PCR, total RNA was purified from *in vitro* cultures according to the manufacturer's protocol (Life Technologies). Reverse transcription was performed with oligo(dT)20 primers. TaqMan probes were used for measurement of various gene's expression, and mRNA relative expression was adjusted to Gapdh (Mm03302249_g1; Life Technologies).

Primers: mPth (Mm01271501_m1 Mm00451600_g1), mNts (Mm00481140_m1), mIl13 (Mm00434204_m1), mIl5 (Mm00439646_m1), mSlc15a3 (Mm00491666_m1), mSlc2a6 (Mm00554217_m1), mCcl17 (Mm00516136_m1), mTimd2 (Mm00506693_m1), mIl10 (Mm00439614_m1), mIl4 (Mm00445259_m1), mMyo6 (Mm00500651_m1), mIl1r1 (Mm00434237_m1), mgata3 (Mm00484683_m1).

Statistical analysis.

Sample sizes were determined empirically. Differences between data sets of similar variance were analyzed by unpaired two-tailed Student's t-test. A p value <0.05 was considered significant. ns: p > 0.05; *: p \leq 0.05; **: p \leq 0.01; ***: p \leq 0.001; ****: p \leq 0.0001

Figure legend

FIG 1. IL-13 is increased and IL-4 decreased when Th2 cells are differentiated in presence of IL-1 β

A, IL-13 and IL-4 expression on Th1, Th17 and Th2 cells differentiated in the presence of IL-1 β , anti-IL-1 α/β or anakinra. **B**, Kinetic analysis of IL-1R1 expression. **C, D**, IL-13, IL-4 and IL-5 expression on Th2 groups sorted based on IL-1R1 expression. Statistical analyses were compared to the IL-1 β IL-1R+ group.

FIG 2. iTh2 cells induce lung hyper eosinophilia and goblet cell metaplasia

A-F, Wild type mice were transferred with 5C.C7 Th2 cells sorted as in Fig. 1C and rechallenged IN. **B, D, I, K**, Eosinophils count after IN challenge. **C, E, F, J, L**, Lung sections stained with PAS, and scored for inflammation as described in *Methods*. Arrows indicate mucus-producing cells (magenta). Wild type (**G-I**) and ROR γ t^{-/-} mice (**J-L**) were sensitized with HDM + anakinra or IL-1 β and rechallenged IN. **H**, CD44^{hi} CD4⁺ T cells were analyzed for IL-13 and IL-4 expression.

FIG E1. IL-1R, Myd88 and NF- κ B expression are required for IL-13 IL-1 β -dependent enhancement.

A, “anti-IL-1, IL-1R1-“ and “IL-1 β , IL-1R1+” Th2 cells were reprimed under neutral, Th1 or Th2 conditions and then re-assessed for IL-4 and IL-13 expression. **B**, Sorted 5C.C7 Th2 cells “anti-IL-1, IL-1R-“ or “IL-1 β , IL-1R+” were transferred into normal B10.A CD45.2 mice, and rechallenged intranasally with PCC + anakinra or IL-1 β respectively. Statistical analysis of IL-4 and IL-13 expression on the transferred T cells found in the lungs. **C**, OT-II; OT-II IL-1R $^{-/-}$, or OTII Myd88 $^{-/-}$ CD4 $^{+}$ T cells were cultured with wild type-T-depleted splenocytes under Th2 + anti-IL-1 or Th2 + IL-1 β conditions, and then tested for IL-13 and IL-4. **D**, 5C.C7 Th2 cells were differentiated \pm anti-IL-1 α/β for 24h. NF- κ B activation inhibitor + anti-IL-1 α/β or IL-1 β were added and cultured for an additional 3 days.

FIG E2. Gene expression analysis of “IL-1 β , IL-1R+” versus “anti-IL-1, IL-1R-“ groups

A, IL-13 and IL-4 regulatory regions and map of locus with DNase I HS sites. 5C.C7 Th2 cells primed with anti-IL-1 or IL-1 β were sorted as in Fig. 1C. ChIP analysis on IL-13 and IL-4 promoter region was performed immediately. **B**, RT-PCR analyzes were performed with total RNA isolated from Th2 “anti-IL-1, IL-1R-“ and Th2 “IL-1 β , IL-1R+” cell cultures. Representative data presented is the ratio between both groups. **C**, cAMP functional response to biologically active PTH was measured on 24h supernatant collected from Th1, Th2 “anti-IL-1, IL-1R-“ and Th2 “IL-1 β , IL-1R+” cell cultures primed after 4 days and restimulated with platebound anti-CD3/CD28. **D**, PTH ELISA was measured according to manufacturers’ recommendations.
