* Supporting Information

ABSTRACT: A series of novel, intramolecular Zr(IV)/P frustrated Lewis pairs (FLPs) based on cationic zirconocene fragments with a variety of ancillary cyclopentadienyl and 2-phosphinoaryloxide ($-O(C_6H_4)PR_2$, R = ^tBu and 3,5-CF_3-(C_6H_3)) ligands are reported and their activity as catalysts for the dehydrocoupling of dimethylamine-borane (Me₂NH-BH₃) assessed. The FLP system [(C₉H₇)₂ZrO(C₆H₄)P^tBu₂]-[B(C₆F₅)₄] is shown to give unprecedented turnover frequencies (TOF) for a catalyst based on a group 4 metal (TOF ≥ 600 h⁻¹), while also proving to be the most efficient FLP catalyst reported to date. The mechanism of this reaction has been probed using analogous intermolecular Zr(IV)/P

FLPs, permitting deconvolution of the reactions taking place at both the Lewis acidic and basic sites. Elucidation of this mechanism revealed an interesting cooperative two-cycle process where one cycle is FLP mediated and the other, a redistribution of a linear diborazane intermediate, relies solely on the presence of a Zr(IV) Lewis acid.

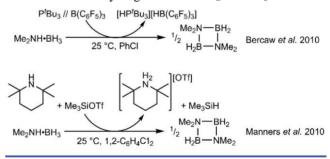

KEYWORDS: frustrated Lewis pairs, FLP, amine-borane, dehydrocoupling, zirconocenes

1. INTRODUCTION

Catalytic dehydrogenation and dehydrocoupling of amineboranes is of broad current interest due to their potential applications as hydrogen storage materials,¹ as reagents for hydrogen transfer to organic or inorganic substrates,² and as precursors to BN-based ceramics and polymeric materials.³ There exists a wide range of transition-metal-based catalysts which facilitate these transformations;⁴ however, work has also been carried out exploring the use of catalysts based on main-group elements. As a consequence dehydrogenation method-ologies which employ catalysts based on elements from group 2 (Mg, Ca) and group 3 (Al, Ga, Sc, Y) are now known.⁵ Furthermore, simple Brønsted acid/base and Lewis acid catalysts can be used to promote hydrogen release from ammonia–borane (H₃N·BH₃).⁶

In recent years solution-phase combinations of sterically encumbered Lewis acids and Lewis bases, frustrated Lewis pairs (FLPs),⁷ have also been shown to mediate these dehydrogen-ation reactions. Initially the focus was on metal-free FLP systems which were able to dehydrocouple dimethylamine– borane (Me₂NH·BH₃) stoichiometrically (Scheme 1).⁸ More recently, however, there have been reports of FLPs based on main-group elements which are able to mediate this trans-formation in a catalytic fashion. In 2013 Uhl, Slootweg, et al. reported an intramolecular Al/P FLP capable of dehydrogen-ating Me₂NH·BH₃ under melt conditions (45 °C, 9.3 mol %), complete consumption of the monomer is achieved by heating to 90 °C for 45 min, however, only a 71% yield of the desired

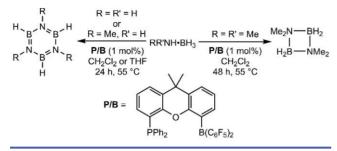

Scheme 1. Main-Group FLPs Capable of Mediating the Stoichiometric Dehydrogenation of Me₂NH·BH₃

product was obtained.⁹ Aldridge et al. have developed a P/B FLP, based on a dimethylxanthene backbone, which is able to dehydrogenate a wider range of amine-borane substrates (RR'NH·BH3, R = R' = H, R = Me and R' = H, R = R' = Me); however, the reaction still requires elevated temperatures and long reaction times (1 mol %, CH₂Cl₂ or THF, 55 °C, 24–48 h) (Scheme 2).¹⁰

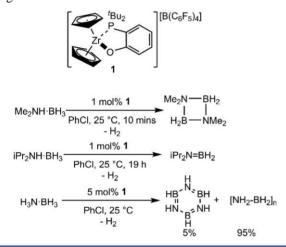

Alongside these breakthroughs, we have developed a range of zirconium(IV) based FLPs with the aim of combining the fascinating small-molecule activation chemistry of FLPs with the well-established catalytic chemistry of the transition metals.¹¹ These transition-metal-based FLP systems (e.g., 1)

Scheme 2. P/B FLP Developed by Aldridge et al. Capable of Mediating the Catalytic Dehydrocoupling of a Range of Amine–Boranes

have been shown to rapidly dehydrocouple several amineborane substrates under ambient conditions to yield the expected products (Scheme 3).^{11b}

Scheme 3. Catalytic Dehydrocoupling of Amine-Boranes using Zr/P FLP 1

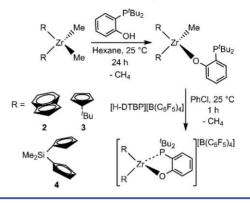

Herein we report a series of novel intramolecular Zr/P FLP systems featuring variations to the ancilliary ligands bound to Zr and also incorporating a weakly Lewis basic phosphine (RP(3,5-CF₃(C₆H₃))₂). These were subsequently applied to the catalytic dehydrocoupling of Me₂NH·BH₃. Crucial insights into the mechanism of this reaction was gained by using a range of previously reported intermolecular Zr(IV)/P FLPs of the type [Cp^R₂ZrOMes][B(C₆F₅)₄]/PR'₃ (R = Me, H; R' = ^tBu, Cy, Et, Ph, Mes, C₆F₅).¹² Such systems permitted deconvolu-tion of the mechanism owing to the ability to separate Lewis acid and Lewis base mediated reactions.

2. RESULTS AND DISCUSSION

2.1. Synthesis of Novel Intramolecular Zr/P FLP Systems. The synthetic approach employed is analogous to that previously used by us to access intramolecular FLP system 1.¹¹ This involved synthesis of the relevant dimethylzircono-cene precursor (R₂ZrMe₂) followed by protonolysis with the corresponding alcohol (HO(C₆H₄)P^tBu₂). Subsequently the catalytically active cationic species was generated by reaction with [H-DTBP][B(C₆F₅)₄] (DTBP = 2,6-di-tert-butylpyridine) with concomitant release of 1 equiv of methane (Scheme 4).

The generation of cationic species 2-4 can be monitored by ^{31}P NMR spectroscopy. Upon addition of [H-DTBP][B-(C₆F₅)₄] to the neutral precursors, protonation of the pendant

Scheme 4. Synthesis of Intramolecular Zr/P FLP Systems 2– 4 with a Variety of Ancillary Ligands

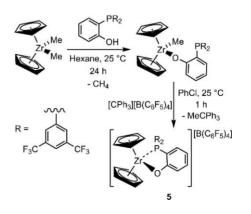

phosphine moiety is observed. This is manifested as a new resonance in the ³¹P NMR spectra (δP 20–25 ppm in all cases) displaying a characteristic P–H splitting pattern (doublet, J_{PH} ca. 400 Hz). Effervescence (CH4) and a concomitant color change (colorless to yellow) is then observed, which is complete within 1 h, resulting in quantitative conversion to a new species, as evidenced by the ³¹P NMR spectra (2, δP 55.9 ppm; 3, δP 58.1 ppm; 4, δP 57.6 ppm). The chemical shifts of these resonances, in comparison to that of 1, suggest the presence of a Zr–P interaction in all cases (for comparison the free ligand δP –5.7 ppm). Attempts to isolate 2–4 by layering PhCl solutions of the species with hexane were unsuccessful and yielded intractable oils. The characterization of 2–4 was therefore carried out in situ (¹H, ¹³C, and ³¹P NMR spectroscopy and ESI-MS).

This methodology had to be adapted when using the more electron deficient phosphine moiety, as protonolysis by [H-DTBP][B(C6F5)4] was found not to yield the desired product, which was attributed to the less basic nature of the phosphine. Upon addition of [H-DTBP][B(C6F5)4], protonation of the pendant phosphine moiety did not occur. This is not unexpected, as the pK_a of the related compound [(p-FPh)₃P-H]⁺ is known to be 1.97 (in H₂O);¹³ however, the pK_a of [DTBP-H]⁺ under the same conditions is 4.95 (in H₂O).¹⁴ As a consequence, [CPh₃][B(C6F5)4] was used to mediate the methyl abstraction reaction and generate the cationic species 5 (Scheme 5).

Interestingly, when this reaction was monitored by ³¹P NMR spectroscopy, no change in the ³¹P NMR spectrum was observed upon formation of 5. This strongly suggests the

Scheme 5. Synthesis of Intramolecular Zr/P FLP System 5 with an Electron-Deficient Phosphine

absence of a Zr–P interaction. Formation of 5 is, however, clearly evidenced by the ¹H NMR spectrum, where loss of the resonance corresponding to the Zr–Me (δ_H –0.07 in PhCl) and the appearance of a new resonance corresponding to triphenylethane (MeCPh₃, δ_H 2.09). Again, isolation of the cationic species was attempted by precipitation into hexanes. However, this only resulted in the generation of intractable solutions and 5 was therefore used in situ.

2.2. Dehydrocoupling of $Me_2NH \cdot BH_3$ using 2–5. Catalyst systems 2–5 (Figure 1) were trialled in the catalytic

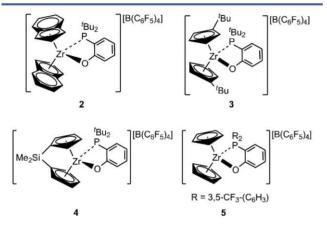

Figure 1. FLP systems 2-5 trialled in the dehydrocoupling of Me₂NH·BH₃.

dehydrocoupling of Me₂NH·BH₃. Initially a 5 mol % catalyst loading was employed and the reaction monitored by ${}^{11}B{}^{1}H{}$ NMR spectroscopy. The results are shown in Table 1, where the previously reported catalyst 1 is shown for comparison.

Table 1. Catalytic Dehydrocoupling of Me₂NH·BH₃ using FLP Systems 2–5 with the Previously Reported Catalyst 1 Included for Comparison^a

catalyst	[Zr] (mol %)	temp (°C)	time (min)	$TOF(h^{-1})$
1	2	25	14	210
2	5	25	1	>600
3	5	25	4	282
4	5	25	9	138
5	5	25	>60	0
^a All reactions were conducted in chlorobenzene in sealed NMR tubes.				

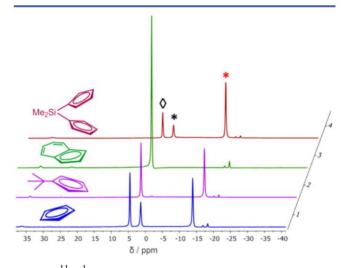

From these data it can be seen that catalyst 5, possessing the electron-withdrawing phosphine, shows no activity even after heating to 80 °C for 7 days. This suggests that the phosphine moiety is required to possess a certain degree of basicity in order to mediate the dehydrocoupling. This strongly implies that NH deprotonation is a key step in the catalytic cycle. This is in good agreement with the behavior noted for the main-group systems and also corroborates the mechanism previously proposed by our group.^{11b}

Further to this, it is observed that 2 is a highly efficient catalyst for the dehydrocoupling of Me₂NH·BH₃ and, in fact, possesses the highest TOF (turnover frequency) of any group 4 catalyst (>600 h⁻¹), the previous highest being the Zr-amide species ([NSiN]^{Dipp}Zr(NMe₂)₂(µ-Cl)Li(THF)₃) reported by Rivard et al. (TOF = 420 h⁻¹).¹⁵ Decreasing the steric bulk present in compound 2 down to the single ^tBu group, offered in compound 3, leads to a decrease in TOF. This decrease

continues with removal of the bulky ^tBu moiety in 1, and finally the lowest TOF is observed with the least sterically hindered system 4 (TOF: 2 > 3 > 1 > 4). However, this is also mirrored by the electronic properties of these species. Indenyl ligands (present in 2) are known to be significantly more electron donating than Cp ligands in 1,¹⁶ with Cp (1) and (Me₂Si)Cp₂ (4) thought to be similar. Due to this, it is difficult to discern whether this change in rate is electronic or steric in nature.

Further examination of the product distribution and intermediates present during the reactions by ${}^{11}B{}^{1}H{}$ NMR spectroscopy revealed not only the expected dehydrocoupling product, cyclodiborazane [Me₂N-BH₂]₂, but also the linear diborazane Me NH-BH-Me N-BH 2 2 2 3

Me₂N BH₂ (II) intermediates (Figure 2). The amounts of

HB(NMe₂)₂ (29 ppm), Me₂N BH₂ (36.6 ppm), and Me₂N(B₂H₅) (-17 ppm) are also observed.

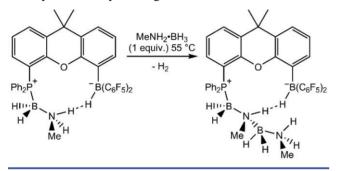

each intermediate (I and II) vary with the ancillary ligand employed. Increasing the steric bulk in the order 4 < 1 < 3 < 2 leads to less I being observed, indicating that the predominant mechanism in these cases involves preferential formation of II. Due to the rapid nature of these reactions, however, the exact ratios of these intermediates could not be calculated.

The presence of both I and II in such dehydrocoupling reactions is unusual. There are thought to be three different mechanisms by which Me2NH·BH3 is converted to the cyclic diborazane product. One possible mechanism is an "on-metal" process where linear diborazane I, the sole intermediate,¹⁷ is generated from a metal-mediated intermolecular dehydrocoupling of two molecules of Me₂NH·BH₃. In a further metalmediated step, dehydrogenative cyclization could occur to yield the cyclic diborazane product. In an alternative "offmetal" mechanism only one of the steps is thought to be metal mediated. In this step one molecule of Me2NH·BH3 is dehydrogenated to produce the aminoborane II.¹⁸ The aminoborane then spontaneously dimerizes to form the cyclic diborazane [Me2N-BH2]2. The third possible mechanism, and one which may be useful in this discussion, has been proposed by Schneider et al.; their calculations show that rearrangement among Me₂NH·BH₃, [Me₂N-BH₂]₂ and II is approximately

thermoneutral (2.0 kcal mol⁻¹) and may take place if "kinetically feasible".¹⁹

In the previous literature it is the off-metal mechanism which is the favored model for FLP-catalyzed dehydrocoupling of Me₂NH·BH₃.^{8,11b} However, with the recent report by Aldridge et al. strongly supporting the viability of a linear chain growth on an FLP catalyst, it appears that the previously proposed mechanisms may require some modification.¹⁰ In their work Aldridge et al. isolated several key intermediates in the P/B FLP catalyzed dehydrocoupling of amine-boranes, suggesting that insertion of 1 equiv of amine-borane into an FLP-bound amine-borane results in the formation of linear oligomeric species akin to those observed with our systems (Scheme 6).

Scheme 6. Growth of a Linear Dimeric Species on a P/B FLP Synthesized by Aldridge et al.

In order to confirm the identity of I as a catalytically relevant intermediate, an authentic sample was treated with 5 mol % of 1 in PhCl at 25 °C. Monitoring the reaction by ¹¹B NMR spectroscopy revealed a product distribution similar to that observed for the reaction of Me₂NH·BH₃ with 1. Species I, II, and Me₂NH·BH₃ were all identified in the ¹¹B {¹H} NMR spectrum shown in Figure 3. Full conversion to the cyclic diborazane was evident after 20 min.

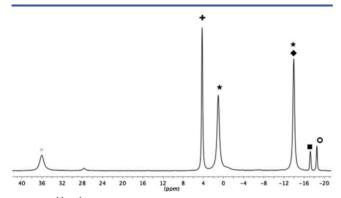

Figure 3. ¹¹B{¹H} NMR spectrum (300 MHz, PhCl, 25 °C, 2 min) of I + 5 mol % 1: (\circ) MeNH(B2H5) (-18.8 ppm); (\bullet) [B(C6F5)4] (-17.5 ppm); (\bullet) Me2NH \cdot BH3 (-14.4 ppm); (\bigstar) Me2NH-BH2-Me2N-BH3 (-14.4 and 0.84 ppm); (+) [Me2N-BH2]2 (4.02 ppm); (\bigstar) Me2N BH2 (36.6 ppm).

This leads us to propose that two different reaction mechanisms occur simultaneously. The first cycle involves simple deprotonation of a Zr κ^2 -amine-borane adduct by a sufficiently basic phosphine to form II, the phosphonium species [R₃P-H]⁺, and Zr-H. An intermediate zirconium amido-borane species is not observed in our experiments, suggesting a concerted pathway with simultaneous deprotona-

tion and hydride abstraction in line with other FLP-type reactions. Subsequent release of H₂ from the phosphonium species and the Zr-H renders the process catalytic. This is similar to the mechanism proposed in our previous work.^{11b} The second proposed process involves insertion of a second equivalent of Me₂NH·BH₃ to yield the linear diborazane I prior to a subsequent cyclization step. The exact nature of this alternative "on-metal" pathway, however, remains unclear and the roles of the Lewis acid and Lewis base in each step was judged to require further investigation. As discussed above, the formation of I may also be reversible and this could prove to be the origin of II in the reaction. To this end we utilized a series of our recently reported analogous intermolecular Zr/P FLP systems to probe this reaction.¹²

2.3. Dehydrocoupling of Me₂NH·BH₃ using Intermolecular FLPs. Initially it was necessary to determine if the intermolecular analogues 7–19 (Scheme 7) retained their

Scheme 7. Generation of Previously Reported Intermolecular FLP Systems				
[Cp* ₂ ZrOMes][B(C ₆ F ₅) ₄] + PR ₃ - 6	PhCl [Cp* ₂ ZrOMes][B(C ₆ F ₅) ₄] // PR ₃ 25 °C 7 R = ${}^{t}Bu$, 8 R = Cy, 9 R = Et 10 R = Ph, 11 R = Mes, 12 R = C ₆ F ₅			
[Cp ₂ ZrOMes][B(C ₆ F ₅) ₄] + PR ₃ - 13	PhCl [Cp ₂ ZrOMes][B(C ₆ F ₅) ₄] // PR ₃ 25 °C 14 R = ^t Bu, 15 R = Cy, 16 R = Et 17 R = Ph, 18 R = Mes, 19 R = C ₆ F ₅			

catalytic activity after removal of the aryl tether. It was found that treatment of Me₂NH·BH₃ with 10 mol % of $[Cp^*_2ZrOMes][B(C_6F_5)4]/PR_3$ (R = ^tBu (7), Cy (8), Et (9), Ph (10), Mes (11), C_6F_5 (12)) in PhCl (25 °C) led to a sluggish reaction resulting in <5% conversion to $[Me_2N-BH_2]_2$ over 24 h in all cases, as calculated by ¹¹B NMR spectroscopy, and when R = Ph, Mes, C_6F_5 no conversion was observed. Changing the ancillary ligands on Zr from Cp* (pentamethylcyclopentadienyl) to Cp (14–19) led to a marked improvement in the reactivity, as shown in Figure 4. This is

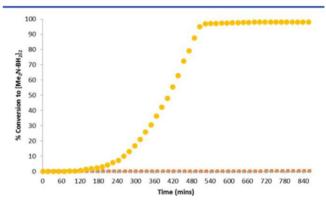

Figure 4. Reaction of Me₂NH·BH₃ with 10 mol % 14–19 (25 °C, PhCl, 14 h): (yellow •) 14; (orange •) 15; (gray \blacktriangle) 16. 17–19 show no reaction with Me₂NH·BH₃.

consistent with previous observations, where intramolecular Zr/P FLPs, bearing Cp ancillary ligands, give significantly more rapid reactivity in comparison to their Cp* cousins.¹¹ Ligands with intermediate steric bulk, specifically in complexes 2 and 3, lead to more subtle effects, with complex 2 in particular giving a highly active catalyst despite having more bulky indenyl ligands.

In contrast to Cp^{*}, the indenyl ligands (and indeed the ligand in complex 3) may orient themselves in such a way as to still not hinder substrate binding. Clearly the different electronic characteristics of these ligands may then come into play in yielding a more active catalyst. The possibility for more facile η^5 to η^3 ring slippage for indenyl during the catalytic cycle may also play a role.

FLP systems 15–19 (10 mol %, PhCl, 25 °C, 14 h) gave low conversion (<5%) to [Me2N-BH2]₂ even after 14 h, with 17–19 showing no conversion over the same period. The lack of conversion using 19 bearing an electron-withdrawing phos-phine is consistent with the result observed with 5. Despite this,

14 shows 97% conversion to [Me2N-BH2]2 in 7.5 h. Interestingly, Figure 4 shows an induction period; this is attributed to the formation of I prior to its consumption to generate [Me2N-BH2]2. In operando NMR spectroscopy (see later) gives no evidence for any gross changes to the catalyst structure during this initiation period; there is also no evidence for the formation of heterogeneous or colloidal species.

2.4. Mechanistic Investigation. Monitoring the reaction between Me₂NH·BH₃ and a catalytic amount of 14 (10 mol %, PhCl, 25 °C, 7.5 h) by ¹¹B{¹H} NMR spectroscopy led to a distribution of reaction intermediates similar to that observed for the reactions with catalysts 1–4 (Figure 1), with both Me₂NH-BH₂-Me₂N-BH₃ (I) and Me₂N BH₂ (II) generated simultaneously (Figure 5 and Figure S1 in the Supporting Information).

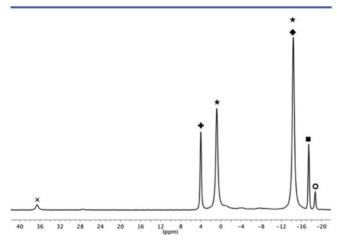

Figure 5. ${}^{11}B{}^{1}H{}$ NMR spectrum (300 MHz, PhCl, 25 °C, 280 min) of Me2NH·BH3 + 10 mol % 14: (\circ) MeNH(B2H5) (-18.8 ppm); (\bullet) [B(C6F5)4] (-17.5 ppm); (\bullet) Me2NH·BH3 (-14.4 ppm); (\bigstar) ${}^{M^{*}NH\cdotBH\cdotMe N\cdotBH}_{2}$ (1) (-14.4 and 0.84 ppm); (+) [Me N-BH2]2 (4.02 ppm); (\bigstar) Me2N BH2 (II) (36.6 ppm).

In order to further probe the mechanism of the reaction, Me₂NH·BH₃ was treated with 10 mol % of [Cp*₂ZrOMes]-[B(C₆F₅)4] (6) and [Cp₂ZrOMes][B(C₆F₅)4] (13) in the absence of a Lewis base. In neither case was dehydrocoupling observed by ¹¹B NMR spectroscopy (24 h, 25 °C, PhCl); however a new Zr amine-borane complex was identified (¹¹B{¹H} δ -11.5 (broad singlet, Me₂NH·BH₃), -16.9 (s, [B(C₆F₅)4]⁻)). In the case of 6, this complex (20) was isolated through a stoichiometric reaction between 5 and Me₂NH·BH₃; the solid-state structure of 20 is shown in Figure 6. From the solid-state structure of 20 it is clear that Me₂NH·BH₃ is bound in a K² fashion;¹⁹ however, the ¹H NMR spectrum shows a broad resonance for three equivalent hydrides, suggesting a

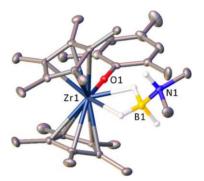

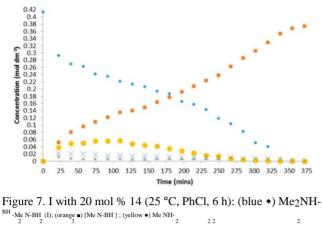

Figure 6. Solid-state structure of the cation present in 20 as determined by X-ray crystallography. Ellipsoids depicted at the 50% probability level. The second unique cation, nonessential hydrogens, and two [B(C₆F₅)₄]⁻ counterions are omitted for clarity. Selected bond lengths (Å) and angles (deg): Zr1-O1 1.968(3), N1-B1 1.587(6); Cp^{*}-Zr-Cp^{*} 135.14(7). The Zr-B distance is 2.709(5) Å.

dynamic structure in solution, where the hydrides bound to Zr are exchanging on the NMR time scale. Structurally characterized transition-metal complexes of amine-boranes bearing N-H moieties are rare, as the isolation of such compounds is usually hindered by subsequent dehydrocoupling reactivity.^{20e,g}

Subsequent reaction of 20 with phosphine Lewis bases (PhCl, 25 °C, <10 min) led to dehydrogenation, release of Me₂N BH₂ (II), and formation of the corresponding phosphonium salt [HPR₃][B(C₆F₅)₄] and a Zr hydride. Aminoborane II subsequently dimerized to form the cyclic diborazane. Protonation of the Zr hydride by the phosphonium species to release H₂ is sluggish (PhCl, 25 °C, <6 h) in the case of the Zr species bearing the Cp* ligands. This is consistent with the slow catalytic turnover achieved with catalyst systems 7–12.

Varying the phosphine is seen to have a dramatic effect on this transformation. More basic phosphines (PR₃, R =^tBu, Cy, Et) show the deprotonation/dehydrogenation reactivity described above. Analogous treatment of 20 with PPh3, PMes3, or P(C6F5)3 showed no reaction after 6 h. This is consistent with the fact that 14-16 are catalysts for the dehydrocoupling reaction, whereas 17-19 show little to no conversion. This dehydrogenation of a Zr-bound amineborane could be one mechanism for the dehydrocoupling of Me₂NH·BH₃; however, this process does not account for the observation of the linear diborazane I. Nevertheless, these findings do indicate the necessity for both the Lewis acidic and Lewis basic fragments in the initial dehydrogenation of Me2NH·BH3, yielding either Me2N BH2 (II) or Me2NH-BH2-Me2N-BH3 (I). Crucially, in support of this hypothesis, addition of further amounts of Me₂NH·BH₃ to 20 leads to the formation of no new products on a catalytically relevant time scale (8 h, 25 °C).

To probe the intermediacy of linear diborazane (I), a chlorobenzene solution of I was treated with 20 mol % of $[Cp_2ZrOMes][B(C_6F_5)_4] // P^tBu_3$ (14) (PhCl, 25 °C, 6 h). In this case complete conversion to $[Me_2N-BH_2]_2$ was observed in 6 h (Figure 7). It is evident from Figure 2 that, upon consumption of I, both II and the parent amineborane, Me₂NH·BH₃ are formed. Redistribution of such linear diborazanes to form amine-borane dehydrocoupling products has been previously reported by our group.²¹

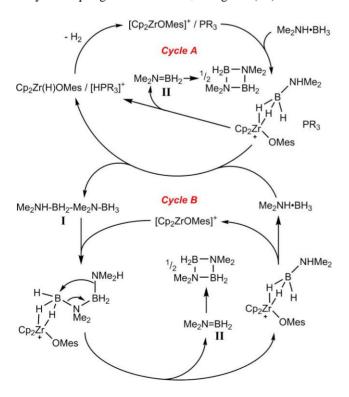

BH₃; (gray \blacktriangle) Me₂N BH₂ (II); (light blue \varkappa) Me₂N(B₂H₅).

In order to determine if this second step in the cycle also requires both Lewis acidic and Lewis basic fragments, the Lewis base ($P^{t}Bu_{3}$) was removed. Reaction of I with 20 mol % 13 (PhCl, 25 °C, 14 h) resulted in the redistribution of linear diborazane intermediate I to yield Me₂NH·BH₃ and Me₂N BH₂ (II), which subsequently cyclodimerized, as expected, to form the cyclic dimer [Me₂N-BH₂]₂. We observe that Me₂NH· BH₃ is not consumed in the absence of exogenous phosphine (no reaction is observed between complex 13 alone and

Me2NH·BH3)

The proposed mechanism for the Zr(IV)/P FLP catalyzed dehydrocoupling of Me₂NH·BH₃ is shown in Scheme 8. Cycle A is analogous to the previously reported mechanism for this transformation,^{11b} wherein the FLP mediates an intramolecular loss of H₂ from Me₂NH·BH₃, forming the aminoborane II. The aminoborane spontaneously dimerizes to form the cyclic diborazane product [Me₂N-BH₂]₂. Alternatively, in the

Scheme 8. Proposed Reaction Mechanism for the Catalytic Dehydrocoupling of Me2NH·BH3 using a Zr(IV)/P FLP

presence of another 1 equiv of Me₂NH-BH₃, an intermolecular dehydrocoupling event could occur to yield the linear diborazane I. This then feeds into cycle B. Cycle B is the phosphine-independent redistribution of I and involves initial complexation of I to the Zr center in a fashion analogous to that observed for 20. Loss of the terminal Me₂NH group, as previously reported in other redistribution reactions,²¹ then occurs, resulting in a μ -amido diborane species, Me₂NH(B₂H₅). As shown in Figures 7 and 8, Me₂NH(B₂H₅) is observed in

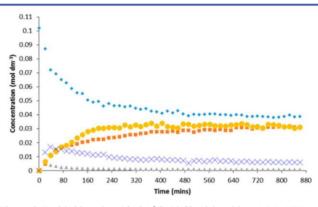

Figure 8. I with 20 mol % 13 (25 °C, PhCl, 12 h): (blue \bullet) Me₂NH-^{BH}-Me N-BH (1); (orange \bullet) [Me N-BH]; (yellow \bullet) Me NH-2 22 22 22 BH3; (gray \blacktriangle) Me₂N BH₂ (II); (light blue \times) Me₂N(B₂H₅).

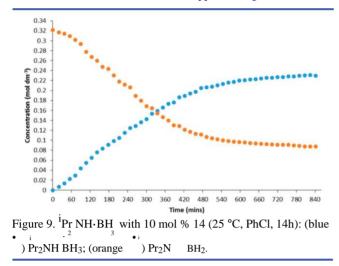

solution throughout these reactions and is thus not thought to be bound to the Zr; in fact, addition of Me₂NH(B₂H₅) to 6 or 13 results in no reaction (vide infra). The fate of Me₂NH-(B₂H₅) remains uncertain. We believe it is likely that the formation of Me₂NH-BH₃ and II could be via an alternative, concerted process from I, as indicated in Scheme 8 (cycle B). When formed, Me₂N BH₂ would spontaneously dimerize to form [Me₂N-BH₂]₂. The formation of this dimer is thought to be the driving force for this step. In the presence of P^tBu₃, Me₂NH-BH₃ could be dehydrocoupled to re-form the linear diborazane I. However, as mentioned above, it is thought that such a transformation cannot occur in the absence of phosphine.

This mechanism also provides some insight into the cause of the differing TOFs depending on the steric bulk of the ancillary ligands in the intramolecular systems (1–4). The increase in steric bulk is thought to preclude the formation of linear diborazane (II), as 2 equiv of Me₂NH·BH₃ is not able to organize around the sterically congested catalytic site. It is therefore thought that in the case of the most sterically bulky system, 2, cycle A is far more dominant and decreasing steric bulk allows cycle B to become more viable.

2.5. Model System for Proposed Cycle A. The intermolecular nature of FLP 14 also allowed us to further probe both cycles A and B. Additional insight into the validity of cycle A can be gained through a systematic study of the dehydrogenation of ⁱPr₂NH·BH₃ by 14. Due to the increased steric bulk around nitrogen, dehydrogenation of ⁱPr₂NH·BH₃ only yields one product, the corresponding aminoborane (ⁱPr₂N BH₂), through an intramolecular loss of H₂.^{17f} This substrate therefore provides an ideal model for cycle A where we propose this intramolecular H₂ elimination to be a catalytically viable pathway. Intramolecular FLP 1 has been shown to dehydrogenate ⁱPr NH·BH (1 mol % [Zr], PhCl, 25

C, 19 h) to yield Pr₂N BH₂; however, revisiting this reaction seemed pertinent in light of the current study.^{11b} Upon

treatment of a PhCl solution of ⁱPr NH-BH with 10 mol % of 14 (25 °C, 14 h) a 73% conversion to ⁱPr₂N BH₂ was observed with no other intermediates apparent (Figure 9).²³

As in the case of Me₂NH·BH₃, reaction of 6 and 13 with i Pr₂NH·BH₃ resulted in no detectable conversion to dehydrocoupling products, but formation of an amine-borane complex was again observed. In the case of the system bearing the Cp* ligand set, this complex (21) has been isolated and crystallographically characterized (Figure 10).

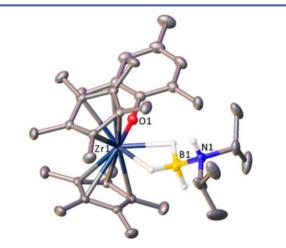

Figure 10. Solid-state structure of the cation present in 21 as determined by X-ray crystallography. Ellipsoids depicted at the 50% probability level. Nonessential hydrogens, solvent of crystallization (PhCl), and $[B(C_6F_5)_4]^-$ counterion are omitted for clarity. Selected bond lengths (Å) and angles (deg): Zr1-O1 1.974(1), N1-B1 1.590(3), Cp^{*}-Zr-Cp^{*} 135.07(3). The Zr-B distance is 2.722(3) Å.

The solid-state structure of 21, as was to be expected, proves to be nearly identical with that of 20, with the amine-borane again bound in a κ^2 fashion.²⁰ In a manner similar to that for 20 treatment of 21 with a stoichiometric amount of P^tBu₃ results in deprotonation of the bound amine-borane and formation of ¹Pr₂N BH₂. These results, when combined with the data in Figure 9, confirm the validity of a mechanistic pathway involving the intramolecular loss of H₂ from an amine-borane mediated by a Zr/P FLP.

2.6. Model System for Proposed Cycle B. Gaining more detailed insight into cycle B has proven to be more of a

challenge, as our initial attempts to isolate the proposed intermediates have been unsuccessful. Attempts to synthesize a Zr-bound linear diborazane have been precluded by the redistribution chemistry described above. Efforts to block this reactivity were also made by capping the linear diborazane with other Lewis bases (DMAP, PMe3; see the Supporting Information for further discussion) but this strategy also proved unsuccessful. In addition, attempts to isolate a Zr µamidodiborane complex were made, but addition of Me2N-(B₂H₅) to 6 or 13 resulted in the formation of no new products, as observed by ¹¹B NMR spectroscopy. Two possible conclusions may be drawn from this. First, that such complexes are transient in solution and therefore isolation is impossible, or second, that the conversion of Me₂N(B₂H₅) to the observed products is in fact not metal-mediated. The latter. however, appears unlikely, as it is known that, in the absence of a catalyst but in the presence of Me2NH, Me2N(B2H5) readily undergoes a ring-opening reaction to yield the corresponding linear diborazane I.²¹

Experiments using alternative linear diborazanes have provided insight into the decomposition pathway of I. Upon reaction of the linear diborazane H₃B-NMeH-BH₂-NMe₂H with different substituents at nitrogen²⁰ with 10 mol % of 13 (PhCl, 25 °C, 14 h) formation of Me₂NH-BH₃ was observed by ¹¹B NMR spectroscopy (Figure 11). This was accompanied by formation of trace amounts of N-methylborazine, [HB-NMe]₃, and μ -N-methylamidodiborane, MeNH(B₂H₅).

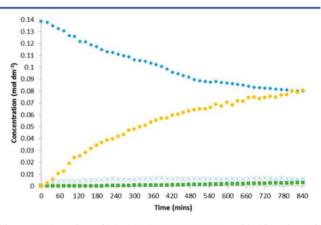

Figure 11. Reaction of Me2NH-BH2-MeNH-BH3 with 10 mol % 13 (25 °C, PhCl, 14 h): (blue •) Me2NH-BH2-MeNH-BH3; (orange •) Me2NH-BH3; (light blue ×) MeNH(B2H5); (green •) [HB-NMe]3.

The origin of these intermediates provides useful information about cycle B in Scheme 8. MeNH(B₂H₅) appears to arise from elimination of the terminal Me₂NH moiety from Me₂NH-BH₂-NMeH-BH₃, with the formation of Me₂NH-BH₃ providing further evidence for the presence of both free amine and free BH₃ in solution. The lack of detectable amounts of Me₂N BH₂ or [Me₂N-BH₂]₂ indicates that any aminoborane that is generated arises from the internal BN unit of the linear diborazane. In this case formation of [HB-NMe] provides further evidence for the presence of MeNH BH₂, as direct observation of this aminoborane by ¹¹B NMR spectroscopy under ambient conditions would prove impossible.²² The borazine [HB-NMe] is thought to arise through trimerization

of MeNH BH₂ to form [MeNH-BH₂]₃, which is further dehydrogenated through now well-established hydrogen trans-fer reactions. 2d,21

3. SUMMARY

A range of intramolecular Zr(IV)/P FLP catalysts have been prepared that are competent in the dehydrocoupling of Me₂NH·BH₃ Moreover, FLP system 2 exhibited the highest TOF yet reported for a catalyst based on a group IV transition metal. Studies of intermolecular FLP analogues allowed elucidation of a novel reaction mechanism comprising two cooperative cycles which provides a new concept for FLPcatalyzed reactions. The first cycle involves a two-step process involving amine-borane coordination and subsequent phosphine-mediated H₂ loss. The second cycle is based on Lewis acid mediated redistribution of a linear diborazane intermediate. The concept that the Lewis acidic and Lewis basic fragments can mediate transformations independently, in addition to acting as an FLP, may have wide-reaching consequences for other FLP-catalyzed reactions. Further studies are underway to widen the substrate scope for these reactions with, in the case of group 13-15 adducts, the formation of polymeric materials as a particular target.

4. EXPERIMENTAL SECTION

4.1. General Considerations. Unless otherwise stated, all manipulations were undertaken under an atmosphere of argon or nitrogen using standard glovebox (MBraun O2 <0.1 ppm, H2O <0.1 ppm) and Schlenk line techniques and all glassware was oven and vacuum-dried prior to use. Cp₂ZrCl₂, Cp*₂ZrCl₂, MeLi (1.6 M in Et₂O), P^tBu₃, PCy₃. PEt3, PPh3, PMes3, and P(C6F5)3 were purchased from Sigma-Aldrich and used as received. [CPh3][B(C6F5)4] was purchased from Acros Organics and used as received. Me2NH·BH3 was purchased from Sigma Aldrich and purified by sublimation prior to use $(25 \text{ °C}, 2 \times 10^{-2} \text{ Torr})$. ¹Pr₂NH·BH₃, Me₂NH-BH₂-Me₂N-BH₃,

[Cp*2ZrOMes][B(C6F5)4] (5), [Cp2ZrOMes][B(C6F5)4] (6),

 $\label{eq:constraint} \begin{array}{l} [Cp_2ZrO(C_6H_4)P^tBu_2][B(C_6F_5)_4] \quad (1), \mbox{ and } o-tBu_2P(C_6H_4)OH \\ \mbox{were synthesized according to literature protocols.} \end{array}$ other reagents were used as obtained unless otherwise stated. Common laboratory solvents (Et₂O, DCM, hexane, THF) were purified using a Grubbs type purification system.²³ Nonstandard solvents (chlorobenzene, pentane) were purchased from Sigma-Aldrich and distilled from CaH₂ prior to use.

NMR spectra were recorded using JEOL ECP-300 (300 MHz), Varian-400 (400 MHz), and Varian NMRS500 (500 MHz) spectrometers. Deuterated solvents were obtained from Sigma-Aldrich (d6-benzene, d8-THF, and d2-DCM) or Apollo Scientific (d5-PhBr) and distilled from CaH2 prior to use. Spectra of airsensitive compounds were recorded using NMR tubes fitted with J. Young valves. NMR spectra of boron-containing compounds were obtained in quartz NMR tubes fitted with J. Young valves.

X-ray diffraction experiments were carried out on a Bruker APEX II diffractometer using Mo K α radiation ($\lambda = 0.71073$ Å). For further details see the Supporting Information.

Mass spectrometry experiments were carried out by the University of Bristol Mass Spectroscopy Service on a Bruker Daltronics micrO TOF II with a TOF analyzer. All samples were run in predried PhCl.

4.2. Synthesis of Intramolecular Zr/P FLPs (2-4). 4.2.1. Syn-thesis of R2ZrMe2 Precursors. 4.2.1.1. Ind2ZrMe2. This compound was

obtained by following a modified literature procedure.²⁴ Methyllithium (1.6 M in Et₂O, 32.3 mL, 51.6 mmol) was added dropwise to a solution of indene (3.00 mL, 25.8 mmol) in Et₂O (35 mL) at room temperature to give a yellow-orange solution. This solution was stirred for 30 min, before addition of ZrCl4 (3.00 g, 12.9 mmol) slurried in hexane (40 mL). The resulting mixture was stirred for 2 h, during which a white precipitate (LiCl) formed. The solvent was removed in vacuo, and the residue was dissolved in hot hexane (50 mL) and filtered through Celite. Removal of the solvent in vacuo gave the desired product as a white powder (3.54 g, 78%) that was recrystallized from hexane at -40 °C. All recorded data are consistent with literature values.²⁴ ¹H NMR (400 MHz, C₆D₆): δ 7.36 (dd, 4H, J

= 2.9, 6.7 Hz, H4.7), 7.06 (dd, 4H, J = 3.1, 6.7 Hz, H6.5), 5.95 (d, 4H, J

= 2.9 Hz, H_{1,3}), 5.79 (t, 2H, J = 3.1 Hz, H₂), -0.68 (s, 6H, Zr(CH₃)₂). 4.2.1.2. Me₂Si(C₅H₄)₂ZrMe₂. The preparation of this compound was adapted from a literature procedure.²⁵ Me₂Si(C₅H₄)₂ZrCl₂ (244 mg, 0.70 mmol) was suspended in hexane (20 mL) and cooled to -78 °C. Methyllithium (1.6 M in Et2O, 0.83 mL, 1.33 mmol) was added dropwise, and the reaction mixture was warmed to room temperature and stirred for 2 h. Solvent was removed in vacuo, and the residue was redissolved in hexane. The resulting solution was filtered through Celite, the volume was reduced to ~ 5 mL, and the temperature was lowered to -20 °C, which resulted in the precipitation of white crystals of the title compound (172 mg, 80%). All recorded data are consistent with literature values.²⁶ ¹H NMR (400 MHz, toluene-dg): δ 6.88 (t, 4H, J = 2.2 Hz, Cp), 5.76 (t, 4H, J = 2.2 Hz, Cp), 0.52 (s, 6H, Si(CH3)2), -0.35 (s, 6H, Zr(CH3)2).

4.2.1.3. (^tBu-C₅H₄)₂ZrMe₂. Methyllithium (1.6 M in hexanes, 0.54 mL, 0.86 mmol) was added dropwise to a stirred solution of the zirconocene dichloride (165 mg, 0.41 mmol) in Et₂O (15 mL) at -78 °C. After addition, the reaction mixture was warmed to room temperature and stirred overnight. Solvent was removed in vacuo, and the resulting residue was extracted with hexanes and the extract filtered through a Celite plug. Solvent was removed in vacuo, yielding a white solid (272 mg, 87%) of the title compound. All recorded data are consistent with literature values. ²⁶ ¹H NMR (400 MHz, CDCl₃): δ 5.80–5.83 (m, 4H, Cp), 5.70–5.75 (m, 4H, Cp), 1.10 (s, 18H, CpC(CH₃)₃), 0.01 (s, 6H, Zr(CH₃)₂).

4.2.2. Synthesis of Neutral Complexes [R2Zr(Me)(O^P(tBu)2)]. 4.2.2.1. General Method. A solution of the dimethylzirconocene (1 equiv) and phosphino alcohol (1 equiv) were individually dissolved in the minimum amount of hexane prior to combination. The resulting solutions were stirred overnight and until no further gas evolution was observed. The solvent was removed in vacuo, yielding the desired complexes.

4.2.2.2. (^tBuC5H₄)₂Zr(Me)(OC₆H₄P(^tBu)₂). Viscous oil (702 mg, 95%). ¹H NMR (400 MHz, C₆D₆): δ 7.61 (dt, 1H, J = 7.6, 1.8 Hz, H6), 7.12–7.16 (m, 1H, H3), 6.77 (t, 1H, J = 7.6 Hz, H4), 6.55 (dd, 1H, J = 5.1, 2.6 Hz, H5), 6.11–6.15 (m, 2H, Cp), 5.90–5.94 (m, UL C), 5.97 (m, 2H, Cp), 1.25 (dd, 19H) 2H, Cp), 5.87–5.89 (m, 4H, Cp), 1.25 (d, 18H, ${}^{3}J_{HP} = 11.3$ Hz, PC(CH3)3), 1.19 (s, 18H, CpC(CH3)3), 0.75 (s, 3H, ZrCH3); FC(CH3)3), 1.19 (s, 181, CpC(CH3)3), 0.73 (s, 51, 22CH3), $^{13}C{}^{1}H$ NMR (125 MHz, C₆D₆): δ 169.8 (d, $^{2}J_{CP} = 23.7$ Hz, C1), 138.8 (s, ipso-Cp(tBu)), 136.0 (d, $^{3}J_{CP} = 3.2$ Hz, C6), 130.1 (s, C3), 125.2 (d, $^{1}J_{CP} = 25.3$ Hz, C2), 120.1 (d, $^{4}J_{CP} = 3.4$ Hz, C5), 118.1 (s, C4), 110.8, 110.7, 109.8, 107.2 (Cp), 32.3 (d, $^{1}J_{CP} = 24.7$ Hz, PC(CH3)3), 30.9 (d, $^{2}J_{CP} = 16.3$ Hz, PC(CH3)3), 29.3 (s, CpC(CH₃)₃), 26.3 (d, $J_{CP} = 6.6$ Hz, ZrCH₃), 22.9 (s, CpC(CH₃)₃). $P\{^{1}H\}$ NMR (161 MHz, C₆D₆): δ 10.17 (s).

4.2.2.3. Ind₂Zr(Me)(OC₆H₄P(^tBu)₂). White solid (567 mg, 95%). ¹H NMR (400 MHz, toluene-d₈): δ 7.57 (dt, 1H, J = 7.7, 1.8 Hz, H6), 7.28 (dq, 2H, J = 8.4, 1.0 Hz, H4,7), 7.21 (dq, 2H, J = 8.4, 1.0 Hz, H4,7), 7.10 (ddd, 1H, J = 8.1, 7.1, 1.7 Hz, H3), 6.87 (ddd, 2H, J = 8.4, 6.6, 1.2 Hz, H6,5), 6.80 (ddd, 2H, J = 8.4, 6.6, 1.2 Hz, H6,5), 6.76 (dt, 1H, J = 7.4, 1.3 Hz, H4), 6.33 (ddd, 1H, J = 8.1, 5.0, 1.3 Hz, H5), 6.06 (ddd, 2H, J = 3.2, 2.1, 0.9 Hz, H1,3), 5.96 (t, 2H, J = 3.3 Hz, H2), 5.73 (ddd, 2H, J = 3.2, 2.1, 0.9 Hz, H1,3), 1.20 (d, 18H, ${}^{3}J_{HP} = 11.4$ Hz, C(CH₃)₃), -0.1 (s, 3H, ZrCH₃). ${}^{13}C{}^{1}H$ NMR (125 MHz, toluene-d₈): δ 168.6 (d, J = 23.9 Hz, C1), 135.6 (d, J = 7.1, C6), 129.8 (s, C3),

125.4 (d, J = 22.7 Hz, C2), 125.2 (s, C_{3a,7a}), 125.0 (s, C3a,7a), 124.4 (s, C5,6), 124.3 (m, C4,7), 124.0 (s, C5,6), 120.29 (d, J = 3.3 Hz, C5), 118.6 (s, C4), 117.6 (d, J = 1.9 Hz, C2), 101.5 (d, J = 1.2 Hz, C1,3), 98.9 (d, J = 1.3 Hz, C_{1,3}), 32.8 (d, J_{CP} = 7.5 Hz, ZrCH₃), 32.4 (d, ¹J_{CP} = 24.9 Hz, C(CH₃)₃), 31.0 (d, ${}^{2}J_{CP} = 15.7$ Hz, C(CH₃)₃). ${}^{31}P{}^{1}H{}$ NMR (161 MHz, toluene-d₈): **ð** 10.23 (s). Anal. Calcd: C, 69.07; H, 6.85. Found: C, 68.92; H, 6.93.

4.2.2.4. Me₂Si(C₅H₄)₂Zr(Me)(OC₆H₄P(^tBu)₂). Viscous colorless oil (227 mg, 98%). ¹H NMR (400 MHz, PhCl-d5): **ö** 7.76 (dt, 1H, J = 7.5, 1.5 Hz, H6), 7.32 (dt, 1H, J = 7.1, 1.2 Hz, H3), 6.96 (dt, 1H, J = 7.7, 1.6 Hz, H4), 6.80-6.82 (m, 2H, Cp), 6.77-6.80 (m, 1H, H5), 6.44-6.46 (m, 4H, Cp), 5.70–5.73 (m, 2H, Cp), 1.36 (d, 18H, ${}^{3}J_{HP} = 10.2$ Hz, C(CH3)3), 0.73 (s, 3H, SiCH3), 0.60 (s, 3H, SiCH3), 0.52 (s, 3H, ZrCH3). ¹³C{¹H} NMR (100 MHz, PhCl-d5): δ 169.9 (d, J = 22.1 Hz,

C1), 135.5 (d, J = 3.5 Hz, C6), 130.3 (d, J = 0.5 Hz, C3), 124.2 (d, J = 22.7 Hz, C2), 122.0 (s, ipso-CpSi), 119.7 (d, J = 2.2 Hz, C5), 119.5 (d, J = 2.7 Hz, C4), 118.4 (s, Cp), 113.6 (s, Cp), 110.6 (s, Cp), 110.5 (s, Cp), 107.5 (s, Cp), 32.2 (d, $^{1}J_{CP} = 24.0$ Hz, C(CH₃)₃), 31.8 (s, ZrCH₃), 30.8 (d, $^{2}J_{CP} = 15.9$ Hz, C(CH₃)₃), -4.96, -5.67 (s, Si(CH₃)₂). $^{31}P{}^{1}H$ NMR (161 MHz, PhCl-d₅): δ 9.96 (s). ESI-MS: 529.1621 [M - H]⁺.

4.2.3. Synthesis of Cationic Complexes $[R_2Zr(O^{P}(^{t}Bu)_2)][B(C_6F_5)4]$ (2–5). Data for the $[B(C_6F_5)_4]$ anion are reported separately. $^{11}B\{^{1}H\}$ NMR (96 MHz, CD₂Cl₂): δ –17.60 (s). ^{19}F NMR (376 MHz, DCM-d₂): δ –133.17 (s), –163.70 (s), –167.71 (s). $^{13}C\{^{1}H\}$ NMR (125 MHz, DCM-d₂): δ 148.26 (d, J = 245.3 Hz, o-B(C_6F_5)_4), 136.68 (d, J

= 242.4 Hz, p-B(C₆F₅)4), 134.76 (d, J = 254.1 Hz, m-B(C₆F₅)4), 124.30 (br, ipso-CB).

4.2.3.1. Via Protonolysis with $[DTBP(H)][B(C_6F_5)4]$. In a glovebox, stoichiometric amounts of the relevant neutral complex $[R_2Zr(Me)-(O^{AP}(^{t}Bu)_2)]$ and $[DTBP(H)][B(C_6F_5)4]$ were weighed into separate vials and dissolved in the minimum amount of PhF (note that PhCl and PhBr can be used interchangeably). The solution of $[DTBP-(H)][B(C_6F_5)4]$ was added dropwise to the vial containing the zirconium complex. Gas evolution was evident, and the resulting solution was stirred for 1 h, yielding bright yellow solutions. Due to inherent instability, the complexes were used in situ to investigate the reactivity toward Me2NH·BH3.

4.2.3.2. $[Ind_2Zr(OC_6H_4P(^{1}Bu)_2)][B(C_6F_5)_4]$ (2). Near-quantitative yield by ¹H NMR. ¹H NMR (400 MHz, PhCl-d5): δ 7.59–7.70 (m, 5H, H6 and H4,7), 7.53 (pseudo t, 1H, J = 7.3 Hz, H3), 7.30–7.40 (m, 5H, H6,5 and H4), 6.57–6.61 (m, 1H, H5), 6.27–6.31 (m, 2H, H1,3), 5.80–5.85 (m, 2H, H2), 5.74–5.80 (m, 2H, H1,3), 1.36 (18H, d, ³J_{HP} = 14.6 Hz, PC(CH3)3). ¹³C{¹H} NMR (125 MHz, PhCl-d5): δ 166.2 (d, ²J_{CP} = 15.6 Hz, C1), 133.6 (d, ⁴J_{CP} = 4.2 Hz, C5), 132.4 (d, ³J_{CP} = 1.2 Hz, C4), 130.1 (s, C6,5), 129.1 (s, C3a,5a), 127.9 (s, C6,5), 125.5 (s, C3a,5a), 125.3 (s, C4,7), 124.4 s, (s, C4,7), 123.0 (d, ¹J_{CP} = 27.0 Hz, C2), 122.8 (d, ³J_{CP} = 3.4 Hz, C6), 122.3 (s, C2), 117.7 (d, ²J_{CP} = 7.4 Hz

5.0 Hz, C3), 103.6 (s, C1,3), 103.5 (s, C1,3), 37.0 (s, ${}^{1}J_{CP} = 7.4$ Hz, PC(CH₃)₃), 29.7 (d, ${}^{2}J_{CP} = 4.5$ Hz, PC(CH₃)₃). ${}^{31}P{}^{1}H{}$ NMR (161 MHz, PhCl-d₅): δ 55.9 (s). ESI-MS: 589.1771 m/z [M + MeOH].

4.2.3.3. [[¹BuC5H4)₂Zr(OC6H4P(¹BU)₂)][B(C6F5)4] (3). Nearquantita-tive yield by ¹H NMR. ¹H NMR (400 MHz, PhCl-d₅): δ 7.13 (dt, 1H, J = 0.9, 7.7, H6), 7.03 (ddd, 1H, J = 1.6, 6.0 Hz, H4), 6.80–6.85 (m, 1H, H5), 6.70–6.75 (m, 2H, Cp), 6.39 (dq, 1H, J = 1.0, 4.5 Hz, H3), 6.25–6.30 (m, 2H, Cp), 6.00–6.08 (m, 4H, Cp), 1.11 (d, 18H, ³J_{HP} = 14.8 Hz, PC(CH₃)₃), 0.90 (s, 18H, CpC(CH₃)₃). ¹³C{¹H} NMR (125 MHz, PhCl-d₅): δ 167.1 (d, ²J_{CP} = 15.2 Hz, C1), 149.9 (s, ipso-Cp(tBu)), 133.8 (d, ⁴J_{CP} = 2.8 Hz, C5), 133.3 (d, ³J_{CP} = 1.4 Hz, C4), 122.1 (d, ¹J_{CP} = 21.3 Hz, C2), 121.9 (s, C6), 118.2 (d, ²J_{CP} = 4.8 Hz, C3), 115.7, 113.3, 113.2, 111.1 (Cp), 37.4 (d, J = 4.9 Hz, PC(CH₃)₃), 31.7 (s, CpC(CH₃)₃), 30.3 (d, J = 4.7 Hz, PC(CH₃)₃), 30.1 (s, CpC(CH₃)₃). ³¹P{¹H} NMR (161 MHz, PhCl-d₅): δ 58.05 (s). ESI-MS: 569.2483 m/z [M]⁺.

4.2.3.4. [Me₂Si(C₅H₄)₂Zr(OC₆H₄P(tBu)₂)][B(C₆F₅)₄] (4). Nearquanti-tative yield by ¹H NMR. ¹H NMR (400 MHz, PhCl-d₅): δ 7.41 (t, 1H, J = 7.8 Hz, H5), 7.14–7.16 (m, 1H, H4), 7.06–7.08 (m, 1H, H6), 6.93 (br s, 2H, Cp), 6.63–6.65 (m, 1H, H3), 6.28 (br s, 2H, Cp), 6.20 (br s, 2H, Cp), 5.37 (br s, 2H, Cp), 1.12 (d, 18H, ³J_{HP} = 13.3 Hz, C(CH₃)₃), 0.82 (br s, 3H, SiCH₃), 0.56 (br s, 3H, SiCH₃). ¹³C{¹H} (100 MHz, PhCl-d₅): δ 165.3 (d, ²J_{CP} = 15.4 Hz, C1), 134.4 (d, ⁴J_{CP} = 1.1 Hz, C5), 132.8 (d, ³J_{CP} = 1.5 Hz, C4), 126.9 (br s, Cp), 122.7 (d, ³J_{CP} = 4.4 Hz, C6), 121.9 (d, ¹J_{CP} = 26.7 Hz, C2), 119.0 (br s, Cp), 118.4 (br s, Cp), 117.3 (d, ²J_{CP} = 6.7 Hz, C3), 116.0 (br s, Cp), 115.4 (s, ipso-CpSi), 37.6 (d, ¹J_{CP} = 6.0 Hz, PC(CH₃)₃), 30.0 (d, ²J_{CP} = 4.6 Hz, PC(CH₃)₃), -5.2 (br s, SiCH₃), -7.3 (br s, SiCH₃). ³¹P{¹H} NMR (161 MHz, PhCl-d₅): δ 57.57 (s). ESI-MS: 513.1313 m/z [M]⁺.

4.3. Synthesis of Intramolecular FLP System 5. 4.3.1. Synthesis of Electron Deficient Phosphino Alcohol. 4.3.1.1. Bis[3,5-bis-(trifluoromethyl)phenyl]chlorophosphine. Magnesium turnings (700 mg) were covered with THF and a solution of 1,3-bis(trifluoromethyl)-5-bromobenzene (4.91 mL, 28.5 mmol) in THF (20 mL) added dropwise with cooling (0 °C). The reaction mixture was stirred at room temperature for 1 h, leading to formation of a

brown solution. The reaction mixture was cooled to 0 °C, and a solution of diethylphosphoramidous dichloride (2.00 mL, 13.7 mmol) in THF (10 mL) wa added dropwise. The reaction mixture was warmed to room temperature and stirred overnight. The solvent was removed in vacuo and the resulting residue dissolved in hexane, filtered through Celite, and concentrated to ~20 mL. Hydrogen chloride solution (2.0 M in Et2O, 13.7 mL, 27.4 mmol) was added dropwise at room temperature and the reaction mixture stirred for 2 h, yielding a white precipitate of the amine hydrochloride. Subsequent filtration and removal of solvent in vacuo yielded the desired chlorophosphine as a white solid (4.45 g, 66%). All recorded data are consistent with those in the literature.^{27 31}P{¹H} NMR (121 MHz, CDCl3): δ 70.4 (s).

4.3.1.2. Bis[3,5-bis(trifluoromethyl)phenyl]phosphine. A solution of (3,5-CF₃-C₆F₃)₂PCl (2.56 g, 5.21 mmol) in Et₂O (12 mL) was added dropwise to a suspension of LiAlH4 (198 mg, 4.27 mmol) in Et₂O (40 mL) at room temperature. The solution was heated at reflux for 2 h and then quenched with degassed H₂O (0.15 mL). Filtration through Celite and removal of solvent in vacuo yielded the desired phosphine as a white solid (2.10 g, 88%). All recorded data are consistent with those in the literature.^{28,29} ¹H NMR (300 MHz, CDCl₃): δ 7.55 (s, 1H, ArH), 7.44 (ps d, 2H, J = 5.7 Hz, ArH), 4.56 (d, 1H, ¹J_{PH} = 223.9 Hz, PH). ³¹P NMR (121 MHz, CDCl₃): δ -41.1 (d, ¹J_{PH} = 216.8 Hz).

4.3.1.3. [Bis(3,5-bis(trifluoromethyl)phenyl)phosphanyl]phenol. 2-Iodophenol (371 mg, 1.69 mmol), (3,5-CF₃-C₆F₃)₂PH (773 mg, 1.69 mmol), Cs₂CO₃ (1.10 g, 3.37 mmol), and palladium(II) acetate (37 mg, 0.17 mmol) were combined in a Schlenk tube and dissolved in toluene (15 mL). The reaction mixture was heated at 100 °C for 16 h. The solution was filtered through a silica plug and eluted with DCM and the solvent removed in vacuo to give the desired product, which was further purified by flash chromatography: silica, DCM/hexane (50/50). Brown solid (817 mg, 88%). ¹H NMR (300 MHz, C₆D₆): δ 7.93 (s, 2H, P-ArH), 7.82–7.83 (pseudo d, 4H, J = 6.9 Hz, P-ArH),

(bedde) (1, 4H, J = 0.9 HZ, F-AH), 7.44 (ddd, 1H, J = 1.7, 7.4, 8.1, H6), 7.02 (dt, 1H, J = 0.9, 7.5, H3), 6.91–6.97 (m, 2H, H4 and H5). ³¹P{¹H} NMR (121 MHz, C6D6): δ -11.0 (s). ¹³C{¹H} NMR (125 MHz, C6D6): δ 158.3 (d, J = 15.7 Hz, C1), 138.7 (d, ¹JCP = 15.7 Hz, ipso-P-Ar), 134.6 (d, J = 8.5 Hz, C5), 133.4 (pseudo d, J = 21.3 Hz, P-Ar), 132.8 (s, C6), 131.7 (dq, ³JCF = 6.3, 34.0 Hz, ipso-C(CF3)), 123.3 (q, ¹JCF = 273.0 Hz, C(CF3)), 123.2 (qu, ³JCF = 3.9 Hz, P-Ar), 121.9 (d, J = 3.7 Hz, C3), 118.1 (d, J = 9.2 Hz, C2), 115.9 (d, J = 1.6 Hz, C4).

4.3.2. Synthesis of Cationic Complex [(C5H 5)2Zr(OC6H4P(m- $CF_{3}C_{6}H_{3})_{2}][B(C_{6}F_{5})_{4}]$ (5). In a glovebox, a solution of the dimethyl zirconocene (1 equiv) and phosphino alcohol (1 equiv) were individually dissolved in the minimum amount of PhF prior to combination. The resulting solutions were stirred for 30 min. [Ph₃C][B(C₆F₅)₄] (1 equiv) was weighed into a separate vial and dissolved in the minimum amount of PhF (note that PhCl and PhBr can be used interchangeably). The solution of [Ph₃C][B(C₆F₅)₄] was added dropwise to the vial containing the zirconium complex. The resulting solution was stirred for 1 h. Due to inherent instability, the complexes were used immediately to investigate the reaction toward Me2NH·BH3. Attempted isolation of both complexes resulted in decomposition. ¹H NMR (300 MHz, PhCl/toluene-ds; aromatic signals are obscured by PhF signals and could not be unambiguously identified): δ δ 6.68-6.72 (m, 2H, H4 and H5), 5.83 (s, 10H, C5H5). ${}^{31}P{}^{1}H{}$ NMR (121 MHz, PhCl/toluene-d8): δ -13.9 (s).

4.4. Dehydrocoupling of Me₂NH·BH₃ by Complexes 2–5. General Method. In a glovebox, a PhCl stock solution of the cationic zirconocene complex (0.025 M) was made as detailed above. A 0.5 mL portion of the solution (0.012 mmol) was added to a glass vial of preweighed Me₂NH·BH₃ (15 mg, 0.25 mmol). A color change from yellow to colorless and evolution of gas was evident. The solution was transferred to a J. Young NMR tube and removed from the glovebox, and the relevant spectra were obtained.

4.5. Reaction of FLP System 1 (5 mol %) with Me₂NH-BH₂-Me₂N-BH₃. In a glovebox 1 (9 mg, 0.008 mmol) and Me₂NH-BH₂-Me₂N-BH₃ (18.6 mg, 0.16 mmol) were weighed out into glass vials and combined in PhCl (0.5 mL). The solution was transferred to a

quartz J. Young NMR tube and then removed from the glovebox. The reaction was monitored by ¹¹B NMR spectroscopy and found to give complete conversion to [Me₂N-BH₂]₂ in 20 min.

4.6. Dehydrocoupling of Me₂NH·BH₃ by Complexes 7–12. In a glovebox [Cp*₂ZrOMes][B(C₆F₅)₄] (6; 21 mg, 0.018 mmol) and the relevant phosphine (0.018 mmol; 7, PtBu₃ 4 mg; 8, PCy₃ 5 mg; 9, PEt₃ 2 mg; 10, PPh₃ 5 mg; 11, PMes₃ 7 mg; 12, P(C₆F₅)₃ 10 mg) were weighed into glass vials. The phosphine was dissolved in PhCl (0.5 mL) and mixed with [Cp*₂ZrOMes][B(C₆F₅)₄] (6). The resulting red solution was added to a glass vial containing Me₂NH·BH₃ (9.5 mg, 0.16 mmol), and the solution was mixed to ensure full dissolution of the amine–borane before it was transferred to a quartz J. Young NMR tube. The tube was subsequently removed from the glovebox, and the relevant spectra were obtained. In all cases the reactions show <5% conversion to [Me₂N-BH₂]₂ after 24 h.

4.7. Dehydrocoupling of Me₂NH·BH₃ by Complexes 14-19. In a glovebox [Cp2ZrOMes][B(C6F5)4] (19 mg, 0.018 mmol) and the relevant phosphine (0.018 mmol; 14, PtBu3 4 mg; 15, PCy3 5 mg; 16, PEt3 2 mg; 17, PPh3 5 mg; 18, PMes3 7 mg; 19, P(C₆F₅)₃ 10 mg) were weighed into glass vials. The phosphine was dissolved in PhCl (0.5 mL) and mixed with [Cp2ZrOMes][B(C6F5)4]. In the cases of 15-17 a color change from orange to yellow was observed indicative of a persistent Zr-P bond. The resulting solutions were added to a glass vial containing Me₂NH·BH₃ (9.5 mg, 0.16 mmol), and the solution was mixed to ensure full dissolution of the amine-borane before it was transferred to a quartz J. Young NMR tube. The tube was subsequently removed from the glovebox, and the relevant spectra were obtained. 15-17 showed <5% conversion to [Me2N-BH2]2 after 14 h. The reaction using 14 was followed by 11 B NMR spectroscopy, and the stacked spectra are shown in Figure S1 in the Supporting Information.

4.8. Synthesis of Compound 20. In a glovebox a chlorobenzene (1 mL) solution of Me₂NH·BH₃ (4 mg, 0.07 mmol) was added dropwise to a chlorobenzene (1 mL) solution of 6 (78 mg, 0.07 mmol). An immediate color change from orange to yellow was observed. The resulting solution was precipitated into a large volume (20 mL) of rapidly stirred pentane. The solvent was decanted off before washing with pentane (3 × 5 mL). The resulting yellow solid was dried in vacuo (65 mg, 79%). Crystals of 20 suitable for analysis by X-ray crystallography were obtained by layering a PhCl solution of 20 with pentane (5 days). ¹H NMR (500 MHz, d5-PhBr): δ 0.54 (3H, br s, Me₂NH·BH₃), 1.49 (30H, s, Cp^{*}), 1.77 (6H, s, ortho-CH₃), 2.02 (3H, s, para-CH₃), 2.12 (6H, s, Me₂NH·BH₃), 3.60 (1H, br s, Me₂NH·BH₃), 6.56 (2H, s, Ar-H). ¹³C NMR (125 MHz, d5-PhBr): δ 15.3 (s, Cp^{*}), 24.0 (s, ortho-CH₃), 26.2 (s, para-CH₃), 47.7 (s, Me₂NH·BH₃), 128.5 (s, Cp^{*}), 159.1 (s, ipso-C). Other aromatic peaks are obscured by the PhBr solvent. Signals corresponding to [B(C₆F₅)4]⁻ are also present as reported above. ¹¹B NMR (96 MHz, d5-PhBr): $\delta -16.9$ (s, [B(C₆F₅)4]⁻), -11.5 (br s, Me₂NH·BH₃).

4.9. Deprotonation of 20 with PR3. In a glovebox 20 (20 mg, 0.016 mmol) and the corresponding phosphine (0.016 mmol; PtBu3 3 mg; PCy3 5 mg; PEt3 2 mg; PPh3 5 mg; PMes3 6 mg; P(C6F5)3 9 mg) were weighed into a glass vial and dissolved in chlorobenzene (0.5 mL). The resulting solution was transferred to a quartz J. Young NMR tube and removed from the glovebox. The reaction was monitored by ¹¹B and ³¹P NMR spectroscopy.

4.10. Reaction between Me2NH-BH2-Me2N-BH3 and 20 mol % of 14. In a glovebox [Cp2ZrOMes][B(C6F5)4] (37 mg, 0.036 mmol) and the PtBu3 (8 mg, 0.036 mmol) were weighed into glass vials. The phosphine was dissolved in PhCl (0.5 mL) and mixed with [Cp2ZrOMes][B(C6F5)4]. The resulting solution was placed in a glass vial containing Me2NH-BH2-Me2N-BH3 (18.6 mg, 0.16 mmol), and the solution was mixed to ensure full dissolution of the amine–borane before it was transferred to a quartz J. Young NMR tube. The tube was subsequently removed from the glovebox, and the relevant spectra were obtained (Figure S2 in the Supporting Information).

4.11. Reaction between Me₂NH-BH₂-Me₂N-BH₃ and 20 mol % of 6. In a glovebox [Cp₂ZrOMes][B(C₆F₅)4] (37 mg, 0.036 mmol) was weighed into a glass vial and dissolved in PhCl (0.5 mL). The resulting solution was placed in a glass vial containing Me₂NH-BH₂-

Me₂N-BH₃ (18.6 mg, 0.16 mmol), and the solution was mixed to ensure full dissolution of the amine-borane before it was transferred to a quartz J. Young NMR tube. The tube was subsequently removed from the glovebox, and the relevant spectra were obtained (Figure S3 in the Supporting Information).

4.12. Reaction between ¹Pr₂NH·BH₃ and 10 mol % of 14. In a glovebox [Cp₂ZrOMes][B(C₆F₅)₄] (18 mg, 0.018 mmol) and the PtBu₃ (4 mg, 0.018 mmol) were weighed into glass vials. The phosphine was dissolved in PhCl (0.5 mL) and mixed with [Cp₂ZrOMes][B(C₆F₅)₄]. The resulting solution was placed in a glass vial containing ¹Pr₂NH·BH₃ (20.5 mg, 0.18 mmol), and the solution was mixed to ensure full dissolution of the amine-borane before ot was transferred to a quartz J. Young NMR tube. The tube was subsequently removed from the glovebox, and the relevant spectra were obtained (Figure S4 in the Supporting Information).

4.13. Synthesis of Compound 21. The methodology used for the synthesis of 21 was analogous to that employed for the synthesis of 20. In a glovebox a chlorobenzene (1 mL) solution of ⁱPr₂NH·BH₃ (4 mg, 0.03 mmol) was added dropwise to a chlorobenzene (1 mL) solution of 6 (40 mg, 0.03 mmol). An immediate color change from orange to yellow was observed. The resulting solution was precipitated into a large volume (20 mL) of rapidly stirred pentane. The solvent was decanted off before washing with pentane (3 × 5 mL). The resulting yellow solid was dried in vacuo (35 mg, 79%). Crystals of 21 suitable for analysis by X-ray crystallography were obtained by layering a PhCl solution of 21 with pentane (2 days). ¹H NMR (500 MHz, d₅-PhCl): δ 1.04 (12H, d, ⁱPr₂NH·BH₃), 1.69 (30H, s, Cp*), 1.97 (6H, s,

ortho-CH₃), 2.18 (3H, s, para-CH₃), 3.09 (2H, m, $^{\rm i}Pr_2NH\cdot BH_3$), 3.35 (1H, br s, Me_2NH\cdot BH_3), 6.72 (2H, s, Ar-H). $^{\rm 13}C$ NMR (125 MHz, d5-

PhCl): δ 11.6 (s, Cp^{*}), 19.4 (s, ortho-CH₃), 19.7 (s, ¹Pr), 26.2 (s, para-CH₃), 54.3 (s, ⁱPr), 123.3 (s, meta-C), 128.5 (s, Cp^{*}), 155.7 (s, ipso-C). Other aromatic peaks are obscured by the PhCl solvent. Signals corresponding to [B(C₆F₅)₄]⁻ are also present as reported above. ¹¹B NMR (96 MHz, d5-PhCl): δ -16.9 (s, [B(C₆F₅)₄]⁻), -9.5 (br s, ⁱPr₂NH-BH₃).
