

Supplementary Figure 3. Permutation testing. $-\log_{10}(P\text{-value})$ of the heritability estimates per facial segment for sons and daughters. Each node corresponds to the facial segments depicted in **Figure 3**. Black-encircled facial segments had p-values below the significance threshold correcting for the multiple-testing burden ($\alpha = 1.3889 \times 10^{-3}$). All significance tests were based on 1,000,000 permutations.
