A supercapacitor is well recognized as one of emerging energy sources for powering electronic devices in our daily life. Although various kind of supercapacitors have been designed and demonstrated, their market aspect could become advanced if the utilisation of other physicochemical properties (e.g. optical) is incorporated in the electrode. Herein, we present an electrochromic supercapacitor (smart supercapacitor) based on a nanoflake NiMoO₄ thin film which is fabricated using a facile and well-controlled successive ionic layer adsorption and reaction (SILAR) technique. The polycrystalline nanoflake NiMoO₄ electrode exhibits a large electrochemically active surface area of $\sim 96.3 \text{ cm}^2$. Its nanoporous architecture provides an easy pathway for the intercalation and de-intercalation of ions. The nanoflake NiMoO₄ electrode is dark-brown in the charged state and becomes transparent in the discharged state with a high optical modulation of 57 %. The electrode shows a high specific capacity of 1853 Fg^{-1} at a current rate of 1 Ag^{-1} with a good coloration efficiency of $31.44 \text{ cm}^2/\text{C}$. Dynamic visual information is obtained when the electrode is charged at different potentials, reflecting the level of energy storage in the device. The device retains 65% capacity after 2500 charge-discharge

27 **Introduction**

28
29 Supercapacitors are promising energy storage devices because of their outstanding
30 characteristics such as high power density, fast charging ability, and excellent electrochemical
31 cycling stability [1–4]. The charge storage mechanism in electrochemical supercapacitors
32 (pseudocapacitors) is associated with the reversible Faradaic reaction. Electrosorption or
33 intercalation processes occur on the surface of an electrode accompanying an electron charge-
34 transfer between electrolyte and electrode, and this reversible reaction often changes the color of
35 the electrode (known as electrochromism) [5]. Devices having such dual functionality are called
36 smart supercapacitors [5,6–19]. Smart supercapacitors store energy as a normal supercapacitor
37 and sense the level of energy stored by changing visual color. Recently, diverse transition metal
38 oxides (TMOs) and complex compounds have been investigated for use as smart supercapacitor
39 electrodes.

wavelength on the horizontal axis is associated with the color of the electrode materials in the colored state. Well-known materials such as WO_3 and its complex compounds, **polyaniline (PANI)**, **carbon nanotubes (CNT)**, and **nickel oxide (NiO)** have been investigated as smart supercapacitors. Attempts have been made to fabricate nanostructured materials to enhance the electrochemical reaction and efficiency using different techniques such as Rf-magnetron sputtering, electrodeposition, hydrothermal, thermal evaporation, spin coating, and chemical vapor deposition [6–19]. The techniques used for the synthesis of nanostructured materials need a long time and a sophisticated experimental setup. Thus, the challenge is to obtain a reliable electrode material that is abundant, non-toxic, and cost-effective, which can be fabricated using simple experimental techniques. Drawbacks, such as high production cost, low reversibility, short lifetime, low chromatic contrast, compromised capacity, and low coloration efficiency, need to be overcome. Based on the literature discussed, it has been noted that NiMoO_4 , which is an abundant material and can be easily synthesized using chemical techniques, has not yet been employed for smart supercapacitor applications. It is anticipated that the electrochemical properties of NiMoO_4 will be satisfactory because Mo can enhance the conductivity of an electrode. There is also the high electrochemical activity of nickel ions.

In this work we report on the synthesis of a binder-free, nanoflake NiMoO_4 thin film electrode on an ITO coated conducting glass substrate by using the **SILAR** technique. The nanoflake NiMoO_4 electrode exhibits bifunctionalities for electrochemical energy storage and electrochromism. A maximum specific capacitance of 1853 Fg^{-1} at 1 Ag^{-1} , with good capacity retention over 2500 cycles, is obtained. During the charging and discharging processes, the electrode shows a color change between dark brown and transparent with good coloration efficiency of $31.44 \text{ cm}^2/\text{C}$.

Experimental

Nanoporous NiMoO₄ thin film electrodes were synthesized on ITO coated conducting glass substrates with a sheet resistance of 27 Ω cm⁻² using the SILAR technique. A NiMoO₄ film was fabricated by successively dipping an ITO substrate in Ni and Mo solution baths (see Fig. S1 in Supplementary Information). One cycle consists of 20 s of dipping in the Ni-containing bath, 10 s in D. I. water, 20 s in the Mo-containing bath, and again, 10 s in D.I. water. Each bath contains 0.1 M NiCl₂·6H₂O and 0.1 M Na₂MoO₄·2H₂O, respectively. **The purpose of the water dipping step is to remove unwanted by-products.** The pH of the Ni-containing bath is adjusted to 12.2 by dropwise addition of an ammonia solution. During the film deposition, the Mo- and Ni-containing baths were maintained at 70 °C and room temperature, respectively. Each cycle consists of ion adsorption and nucleation processes of both the Ni and Mo species at the substrate surface, resulting in the formation of composite NiMoO₄. The NiMoO₄ thin film was grown using 30 successive cycles. Subsequently, the film was annealed at 300 °C for 2 hours, to remove water content and to increase adhesion to the substrate. The thickness and active area of the electrode film are ~ 100 nm and 1×2 cm², respectively. The mass of the active electrode was estimated using a standard weight difference method and it is 0.17 mg.

The electrochemical supercapacitor and electrochromic performance of the NiMoO₄ thin film electrode were investigated using cyclic voltammetry (CV), galvanostatic charge/discharge, and AC impedance analysis. A potentiostat (Princeton Applied Research, Versa STAT 3) was used with a conventional three-electrode electrochemical cell containing a 2 M KOH electrolyte, NiMoO₄ as the working electrode, a saturated calomel electrode (SCE) as the reference electrode, and graphite as the counter-electrode. Electrochemical impedance spectroscopy (EIS) measurements were performed from 1 Hz to 10 kHz (AC), using an impedance analyzer. X-ray

35 **Results and Discussion**

36
37 The crystal structure of the as-prepared nanoflake NiMoO₄, heated to 300 °C, is determined
38 through the X-ray diffraction spectrum. Figure 2(a) shows the X-ray diffraction spectrum of
39 NiMoO₄ nanoflake thin film. The film consists of multiple diffraction peaks revealing its
40 polycrystalline nature. The peaks marked with a star symbol are associated with the ITO
41 substrate. The diffraction peaks observed at 23.08°, 45.26°, 55.68°, 60.26°, 62.02°, and 77.76°
42 are assigned to the (02 $\bar{1}$), (113), (53 $\bar{2}$), (620), (44 $\bar{3}$), and (82 $\bar{2}$) Bragg indexes of a NiMoO₄
43 structure (JCPDS card # 45-0142), suggesting the formation of a NiMoO₄ structure. The
44 polycrystalline nature which provides grain boundaries and granular voids for electrolyte
45 penetration could improve the electrochemical performance of the electrode [5]. To further
46 identify the formation of NiMoO₄, Raman spectroscopy analysis is performed. As shown in the

4 Figure 2 (b), two major peaks at 482 and 813 cm^{-1} , which correspond to Mo-O vibrations and
5
6 Mo=O stretching modes of NiMoO_4 , respectively [20,21], supporting the formation of NiMoO_4 .
7
8 Broad shoulder peaks observed at around 360 and 704 cm^{-1} are ascribed to the asymmetric
9
10 stretching modes of Ni-O-Mo bonds [22].
11
12
13

14 The scanning electron microscopic image of the NiMoO_4 electrode is shown in Fig. 2(c)
15
16 and Supplementary Fig. S2, revealing an interconnected nanoporous network of nanoflakes. The
17
18 nanoporosity of the electrode can allow the electrolyte to penetrate through the electrode. This
19
20 nanoporous architecture is expected to provide a high surface area and easy pathway for ion
21
22 intercalation and de-intercalation. The uniform distribution of the main constituent elements (Ni,
23
24 Mo, and O) is also confirmed by energy dispersive analysis measurements (supporting
25
26 information, Fig. S3).
27
28
29
30

31 Figure 3 shows the HRTEM, SAED, and HAADF-STEM elemental mapping results of
32
33 the NiMoO_4 thin film electrode. The HRTEM (Fig.3 (a)) image clearly resolves lattice fringes of
34
35 nanoflake NiMoO_4 . A lattice distance (d_{222}) of 0.22 nm (Fig.3 (b)) is indexed to the {222} plane,
36
37 which is associated with the NiMoO_4 monoclinic crystal configuration. The SAED image in Fig.
38
39 3(c) shows multiple diffused diffraction rings, which correspond to the $(02\bar{1})$, $(02\bar{2})$, and (201)
40
41 reflections. The appearance of the diffused rings is typical of polycrystalline materials [23].
42
43 Figure 3(d) shows the HAADF-STEM elemental mapping images of nanoflake NiMoO_4 , which
44
45 clearly demonstrates the homogeneous distributions of Ni, Mo, and O elements. The HAADF-
46
47 STEM elemental line scan (1 μm) and EDS spectrum (Fig. S4, Supplementary information)
48
49 further confirms the stoichiometrically presence of Ni, Mo, and O. The atomic ratio of Ni:Mo is
50
51 determined using EDAX, and it is found to be 1:0.45.

3
4 The presence of the constituent elements and the chemical states of the NiMoO₄ film are
5 confirmed using X-ray photoelectron spectroscopy (XPS) analysis. Figure 4 displays the wide-
6 scan survey spectrum, and Ni 2p, Mo 3d, and O 1s core-level spectra of the nanoflake NiMoO₄
7 film. To determine the peak positions in the core-level spectra, the Gaussian-Lorentz distribution
8 function is used. The survey spectrum in Fig. 4(a) reveals the presence of elemental Ni, Mo, and
9 O in the prepared material. For the core-level Ni 2p spectrum in Fig 4 (b), the binding energy
10 peaks at 854.75 and 872.5 eV and their satellite peaks are associated with Ni²⁺ binding states of
11 Ni 2p_{3/2} and Ni 2p_{1/2} [22, 24, 25]. The difference between these two peaks is 17.75 eV, which is
12 related to the formation of Ni²⁺ oxidation states [24, 26]. In the Mo 3d core-level spectrum
13 (shown in Fig.4 (c)), the peaks at 231.12 and 234.25 eV are associated with Mo 3d_{5/2} and Mo
14 3d_{3/2}, respectively. The difference between these two peaks is 3.13 eV, which corresponds to
15 Mo⁶⁺ oxidation states in the film [22, 24]. The peak at 530.5 eV in the O 1s spectrum (Fig 4(d))
16 is linked with metal-oxide bonds [24, 27].

36 The electrochromic properties of the NiMoO₄ nanoflakes electrode are now discussed.
37 Figure 5 (a) shows a cyclic voltammetry (CV) curve of the NiMoO₄ nanoflake electrode at a scan
38 rate of 5 mV/s. The arrow indicates the scan direction during the CV measurement. The pair of
39 redox peaks observed in the CV is an indication of the pseudocapacitive behavior of the
40 electrode. During the anodic scan, an oxidation peak is observed at 0.49V (vs SCE), and the
41 film's color changes to dark brown. For the cathodic scan, the reduction peak appears at 0.18 V
42 (vs SCE), and the film becomes transparent. Both the electrochromic performance and the
43 pseudocapacitive behavior are based on the same mechanism, oxidation and reduction (redox
44 reactions) between Ni²⁺ and Ni³⁺ states. The scan rate dependent CV curves are shown in Fig. S5
45 (Supplementary information). As the scan rate increases, the oxidation and reduction peaks shift.

63
64
65

1
2
3
4 This shift is due to the internal resistance of the electrode. The CV shape, even at a high scanning
5 rate of 50 mV/s, remains similar, suggesting that the electrochemical reaction during
6 charge/discharge processes is stable. The coloration (charging) and bleaching (discharging) are
7 associated with the insertion and de-insertion of OH⁻ ions according to the following equation;
8
9

11
12 The reversible transition between NiO and NiOOH accompanies the charge transfer
13 between Ni²⁺ and Ni³⁺ [3, 28, 29]. The charging and discharging processes are due to the charge
14 transfer of Ni species. These processes are not due to Mo species because the oxidation state of
15 Mo is +6. Mo does not undergo any charge transformation upon OH⁻ ion intercalation during the
16 charging process. Even in the reverse potential scan, Mo does not undergo the reduction process
17 because of the limited potential window. The intercalation of the OH⁻ ion causes the electrode to
18 be in the charged state, with de-intercalation in the discharged state. The charged and discharged
19 states of the electrode can be easily judged by observing the change in color.
20
21

22 The coloring performance of the NiMoO₄ nanoflake electrode is evaluated using optical
23 transmittance measurements. The NiMoO₄ electrode is colored and bleached at ± 0.6 V (vs.
24 SCE) for 30 s. The transmittance spectra of the NiMoO₄ electrode in the colored and bleached
25 states are presented in Figure 5(b). The transmittance difference between the colored and
26 bleached states gives information on the coloration efficiency of the electrode. The change in the
27 optical density (ΔOD) at 630 nm is calculated using the following formula;
28
29

$$30 \quad (\Delta\text{OD})_{630\text{nm}} = \log\left(\frac{T_b}{T_c}\right) \quad (2)$$

31 where T_b and T_c are the transmittances of the bleached and colored states. The electrode is ~ 93
32 % transparent in its original state, but the transparency decreases to 36.23 % in the fully charged
33 state. The sample shows highly reversible color/bleach transmittance characteristics between the
34
35

1
2
3
4 bleached (transparent) and colored states with an optical modulation of ~ 57 % at 630nm. The
5
6
7 (ΔOD) at 630 nm for the NiMoO₄ nanoflake electrode is found to be 0.9440. This obtained ΔOD
8
9 can be used for the estimation of coloration efficiency (CE), which is defined as the change in
10
11 the optical density per unit charge inserted into the electrochromic film. The following formula is
12
13 used to calculate the coloration efficiency [7]:

$$CE_{630nm} = \left(\frac{(\Delta OD)_{630nm}}{Q/A} \right) \quad (3)$$

14
15
16
17
18
19
20 where Q/A is the per unit charge density. The charges inserted into the electrochromic film are
21
22 estimated from chronocoulometry (CC) measurements, shown in Figure 5 (c). The total charge
23
24 per unit area for the film, which is colored at 0.6 V (vs SCE), is measured to be 30.01 mC. Thus,
25
26 the coloration efficiency of the NiMoO₄ nanoflake electrode is calculated to be 31.44 cm²/C.
27
28

29
30 Figure 5(c) shows the CC curves measured at different potentials. During the initial 60
31
32 (fixed time) seconds, the film becomes colored with a positive potential due to the intercalation
33
34 of OH⁻ ions. Subsequently, the film becomes bleached with a negative potential for the next 60
35
36 seconds. Photographs of as-grown and colored films at different potentials are shown in Figure 5
37
38 (d). As the intercalated charges increases, the film becomes dark-brown. The film becomes
39
40 transparent at the discharged state. Thus, the remaining energy level can be easily visualized
41
42 through a simultaneous change in color with varying voltage.
43
44
45
46

47
48 The Electrochemically active surface area (ECSA) is estimated by measuring scan-rate
49
50 dependent CV curves in the non-Faradaic voltage region, which is described by charge
51
52 accumulation rather than redox reaction (Supplementary Figure S5) [30, 31]. A linear increase of
53
54 the capacitive current with respect to the scan rate is observed. Figure 6 (a) shows the non-
55
56
57
58
59
60

Faradaic region of the CV curves at different scan rates. The ECSA for the nanoflake NiMoO₄ sample is estimated using the following expression [30, 31]:

$$ECSA = \frac{C_{DL}}{C_s} \quad (4)$$

where C_s is the specific capacitance of the electrolyte, and C_{DL} is the double-layer region specific capacitance. $C_s = 0.040 \text{ mFcm}^{-2}$ for the KOH electrolyte [31]. The capacitive current (I_{DL}) at different scan rates is estimated from the non-faradic region, as follows:

$$I_{DL} = C_{DL} \times v \quad (5)$$

Figure 6(b) shows the capacitive current (I_{DL}) of the nanoflake NiMoO₄ electrode. Figure 6(c) shows the current at 0.21 V, as a function of scan rate (v). The C_{DL} is the slope of the curve. The ECSA value for the NiMoO₄ electrode is calculated to be $\sim 96.3 \text{ cm}^2$.

The electrochemical supercapacitor properties of the NiMoO₄ nanoflake electrode are now investigated. Figure 7(a) shows its galvanostatic charge-discharge (CD) properties at different current densities. The non-linear and symmetric behavior of the charge-discharge curves suggests the pseudocapacitive nature of the electrode [5]. During the charging and discharging processes, the voltage plateaus at around 0.25 and 0.18 V (vs SCE), associated with the oxidation and reduction processes, respectively. The film is brown in the fully charged state and transparent in the fully discharged state. The specific capacity is calculated using the following equation;

$$C_s = I\Delta t / m\Delta V \quad (6)$$

where C_s is the specific capacitance, and I and m represent the discharge current and the mass of active materials, respectively. ΔV and Δt are the potential window and total discharge time, respectively. The specific capacitance, obtained at different current densities, is presented in

1
2
3
4 Figure 7 (b). The specific capacitance decreases gradually with increasing discharge current
5 density. This decrease is associated with ions diffusing and migrating into the active material.
6
7 The specific capacitance (1853 Fg^{-1}), obtained for the nanoflake NiMoO_4 electrode, is much
8
9 higher than the specific capacitance obtained from other smart supercapacitor electrodes
10
11 (literature survey, summarized in Figure 1). The higher electrochemical capacitance of the
12
13 NiMoO_4 nanoflake electrode is associated with the synergetic effect between nanostructure
14
15 morphology which provides easy path way for the ion diffusion, chemical composition for the
16
17 desired redox reactions, and shorter diffusion length for the faster kinetics.
18
19
20
21
22

23
24 The CV curves measured at different scan rates are used to estimate the scan rate
25
26 dependent specific capacitance of the NiMoO_4 nanoflake electrode using the following formula,
27

$$C_s = \int (IdV) / (2m \times v \times \Delta V) \quad (7)$$

28
29 where C_s is specific capacitance and IdV is the area under the curve. Figure S5 shows the scan
30
31 rate dependent specific capacity of the NiMoO_4 nanoflake electrode. The specific capacity of the
32
33 NiMoO_4 nanoflake electrode is 937 F/g , and it decreases with increasing scan rate.
34
35
36
37

38
39 Electrochemical cycling stability of the nanoflake NiMoO_4 electrode is evaluated at a high
40
41 current density of 10 Ag^{-1} for 2500 cycles. Figure 7(c) shows the specific capacitance as a
42
43 function of cycle number. The specific capacitance decreases gradually as the cycle number
44
45 increases. The capacitance after the 2500th cycle is 301 Fg^{-1} , which is 65 % retention of the
46
47 initial capacity. A gradual decrease in specific capacity can be from structural damage to an
48
49 electrode, which increases the electrical resistance of the electrode [32, 33].
50
51
52

53
54 The coulombic efficacy η of the NiMoO_4 nanoflake electrode is estimated using the
55
56 following expression:
57

$$\eta = T_d / T_c \times 100 \quad (8)$$

1
2
3
4 where T_d is the discharge time and T_c is the charge time. Figure 7(c) represents the measured

where T_d is the discharge time and T_c is the charge time. Figure 7(c) represents the measured coulombic efficiency as a function of cycle number. The overall coulombic efficiency of the sample is larger than 95%, revealing their excellent cycling performance and reversibility.

Figure 7(d) shows a Nyquist plot of the nano-flake NiMoO_4 electrode, before and after 2500 charge-discharge cycles along with equivalent circuit diagram. The Nyquist plots are recorded in the frequency range of 1Hz to 10 kHz. Nyquist plots consist of a semicircle in the high-frequency region and slight straight line in the low-frequency region, which are attributed to the charge transfer resistance (R_{ct}) and Warburg impedance W of the electrode material, respectively. The intersection of the semicircle in the x-axis indicates the internal resistance of the electrodes (R_s), which is a combination of the intrinsic resistance of the substrate and electrolyte resistance of the electrochemical system, CPE is the constant phase element. The fitted impedance parameters are provided in supplementary table S1. The R_s value of the nano-flake NiMoO_4 electrode before and after cycling are 44.66 and 48.38 Ω , respectively indicating constancy of the electrochemical system used to estimate impedance data. The charge-transfer resistance (R_{ct}) of the electrode is found to be 42.69 and 75.08 Ω before and after cycling respectively. The increased electrochemical resistance with cycle number is associated with the structural reconstruction of the nano-flake NiMoO_4 electrode during charge-discharge processes.

The power (P) and energy (E) densities (Ragone plot) are calculated from the charge/discharge measurements, using the following equations:

$$E = 0.5 \times C_s \times \Delta V^2 \quad (9)$$

$$P = E / \Delta t \quad (10)$$

1
2
3
4 Figure 8 shows a Ragone plot for power (P) and energy (E) densities of the nanoflake NiMoO₄
5
6 electrode. The energy density decreases with increasing power density, exhibiting a high energy
7
8 density of 117 Wh/kg at a given power density of 7527 W/kg compared with other oxide
9
10 materials [34,35]. The steep slope in the P - E plot indicates the electrode's superior
11
12 supercapacitive performance, even at high current rates.

19 **Conclusions**

20
21
22 For the first time, we successfully demonstrate a balance-visualized smart supercapacitor
23
24 via employing electrochromic nanoflake NiMoO₄. A facile and robust synthetic strategy is
25
26 developed for the growth of a polycrystalline nanoflake NiMoO₄ nanostructure. A high specific
27
28 capacitance of 1853 Fg⁻¹ at a current density of 1 Ag⁻¹ is obtained, with good coloration
29
30 efficiency of 31.44 cm²/C. The nanoflake NiMoO₄ electrode can generate an energy density of
31
32 117 Wh/kg at a power density of 7527 W/kg. The electrode also shows stable long-cycle
33
34 performance over 2500 charge-discharge cycles. The as-prepared electrode exhibits fast and
35
36 reversible color modulation between the charged (dark-brown) and discharged (transparent)
37
38 states which offers dynamic visual information on the status of power storage. Our findings
39
40 suggest an efficient pathway for material design for high-performance intelligent multi-
41
42 functional electrochemical energy storage devices. **The NiMoO₄ nanoflake electrode would be
43
44 excellent capacitor and good counter electrode in WO₃-based electrochromic devices where both
45
46 electrodes contribute to the coloration.**
