CI - Confidence interval

EHR – Electronic Health Record

NAMCS - National Ambulatory Medical Care Survey

CLR – Conditional Logistic Regression

Abstract

Objective: We investigate the joint observation between type 2 diabetes and headache using a case-control study of a US ambulatory dataset.

Background: Recent whole-population cohort studies propose that type 2 diabetes may have a protective effect against headache prevalence. With headaches ranked as a leading cause of disability, headache-associated comorbidities could help identify shared molecular mechanisms.

Methods: We performed a case-control study using the US National Ambulatory Medical Care Survey, 2009, on the joint observation between headache and specific comorbidities, namely type 2 diabetes, hypertension and anxiety, for all patients between 18 and 65 years of age. The odds ratio of having a headache and a comorbidity were calculated using conditional logistic regression, controlling for gender and age over a study population of 3,327,947 electronic health records in the absence of prescription medication data.

Results: We observed estimated odds ratio of 0.89 (95% CI: 0.83-0.95) of having a headache and a record of type 2 diabetes over the population, and 0.83 (95% CI: 2.02-2.57) and 0.89 (95% CI: 3.00-3.49) for male and female, respectively.

Conclusions: We find that patients with type 2 diabetes are less likely to present a recorded headache indication. Patients with hypertension are almost twice as likely of having a headache indication and patients with an anxiety disorder are almost three times as likely. Given the possibility of confounding indications and prescribed medications, additional studies are recommended.

Introduction

Headache, including tension-type headaches, migraine and medication overuse headaches, is the most common neurological disorder¹. The percentage of the adult population with an active headache disorder is as much as 47 % for a headache in general, 10 % for migraine, 38% for tension-type headache, and 3 % for chronic headache². With the World Health Organization ranking migraine among the top causes of years of healthy life lost to disability³, there is an unmet medical need for therapeutic intervention. However, our understanding of what causes a headache and the association between specific comorbidities and headache prevalence remains unclear.

The positively-correlated association between hypertension disorders⁴⁻⁸ and psychiatric disorders⁹⁻¹³, such as depression and anxiety, has been long established in the literature. Other co-morbidities influencing headache incidence or severity have been reported although the evidence for association with headache has been less robust. Diabetes for example has been suggested to have a protective effect¹⁴⁻¹⁷ although whether the association between headache and type 2 diabetes remains unclear and whether reported effects are due to overlapping molecular mechanisms or to off-target pharmacological effects of diabetes treatment is equally unknown. A possible role for the insulin receptor in migraine pathogenesis was suggested after five significant single nucleotide polymorphism (SNP) variations were found over-represented in the insulin receptor gene in migraine patients. This association was independently replicated in a case-control population collected separately¹⁴. Other related observations include higher insulin levels, a condition associated with prediabetes, in migraineurs than in controls and elevated blood-glucose levels in patients

with typical headache¹⁵. Furthermore, population-based prospective studies have yielded a significant association between a decreased risk of migraine with type 2 diabetes^{16,17}.

Nonetheless, a number of published studies have not reported an apparent protective effect of diabetes. A case-control study examining insulin resistance in migraineurs did not find a significant association with migraine, although the results remained inconclusive given the small sample population and due to several patients with a low disease activity¹⁸. A cross-sectional study on chronic migraine prevalence in women suggests that chronic migraine is actually positively associated with insulin resistance, particularly when in partnership with obesity¹⁹. Yet, a different study on the prevalence of migraine in patients with type 2 diabetes failed to find a positive association²⁰. Finally, although a recent cross-sectional population-based study also failed to identify an inverse relationship between type 2 diabetes and headache, an association between type 1 diabetes and both headache (OR = 0.55, 95% CI 0.34-0.88) and migraine (OR = 0.47, 95 % CI 0.26-0.96) was found²¹.

Several abnormalities associated with insulin resistance have been reported in patients with migraine²². Glucose plasma concentrations were significantly higher in migraineurs with insulin sensitivity impaired in migraine²². Studies suggest that insulin resistance is associated with migraine²² and insulin resistance is also associated with type 2 diabetes²³. Patients with migraine frequently report that fasting, a condition where there is an insulin receptor activation, is a trigger of headache attacks²⁴ whilst a separate study revealed that a low-sucrose diet may reduce the frequency of migraine attacks²⁵. Clearly, the relationship between headache and type 2 diabetes remains unresolved.

We sought to investigate the joint observation between type 2 diabetes and headache using a case-control study exploiting a large US ambulatory electronic health record (EHR) dataset containing over 6.5 million records. The ICD-9 indication codes presented in the

dataset were grouped by the tested comorbidity indications, headache, type 2 diabetes, anxiety and hypertension. To validate our method, we also examined the well-studied relationships between headache with hypertension and headache with anxiety.

Methods

Data source: We calculate the odds ratio of a joint observation between headache and specific comorbidities using data from The US National Ambulatory Medical Care Survey (<https://www.cdc.gov/nchs/ahcd/index.htm>), 2009. This is a cross sectional national probability sample survey that sampled 6,552,504 subjects randomly. The survey was conducted by the Division of Health Care Statistics, National Center for Health Statistics, and the Centers for Disease Control and Prevention. As of 2006, NAMCS includes a sample of community health centers, using information from the Health Resources Service Administration and the Indian Health Service. Demographic information from these participants include sex, race, patient age in years, year surveyed, and up to seven ICD-9 code entries for disease. Public use datasets and instruction files related to this study can be found at https://www.cdc.gov/nchs/ahcd/datasets_documentation_related.htm.

Study population: The US NAMCS dataset was reduced to a study population of 5,661,688. The sample population was restricted by age (18 to 65 years in age, inclusive), required a gender entry, and at least one valid medical indication. Records with an indication from the ICD-9 groups “8[0-9][0-9]” or “9[0-9][0-9]”, which could link a headache to a secondary indication of injury or poisoning were removed.

Exposure: We defined a headache indication as any record from the study population with an ICD-9 code from the groups 339.*, 784.0* and 307.81. These grouped codes represent; *other headache syndrome, including cluster headache and tension headache; headache characterized by a sensation of marked discomfort in various parts of the head and neck; and tension headache specifically related to psychological factors*, respectively. We defined a type 2 diabetes indication as any record from the study population with an ICD-9 code of either 250.00 or 250.02. All indications of anxiety, dissociative and somatoform disorder were defined by the ICD-9 code group 300.*, and collectively referred to as anxiety disorders for the purpose of this study. We defined a hypertension indication as any records from the study population with an ICD-9 code from the group 401.*; these codes include malignant essential hypertension, benign essential hypertension and unspecified essential hypertension.

Statistical Analysis: We perform a case-control study to analyze the joint observation between each of the three conditions, namely anxiety, hypertension and type 2 diabetes, with a headache indication. The prevalence of each condition alone and each condition accompanied by a headache indication was calculated over the study population and then controlling for gender. Conditional logistic regression (CLR) with a 95% confidence interval (CI) was used to estimate an odds ratio (OR) of disease observation by matching age and gender for two controls (absence of headache) per case of headache indication. Male and female specific disease observations were calculated separately. A P-value < 0.01 was considered statistically significant. Statistical analyses were performing using R software version 3.4.3.

Results

Identification of diseases.

Disease indications were grouped by their ICD-9 codes (Table 1). Headache codes were collected using the classification for a tension headache and general diagnosis for headache. Instances of cluster headache were excluded due to their infrequency within the sampled population. The grouped anxiety indications were collected using the ICD-9 tree from EHRs that matched the regular expression 300.*. These codes included indication for anxiety, phobias, dissociative disorders and somatization disorders. The grouped hypertension indications were matched using the regular expression 401.*. Only three hypertension ICD-9 codes, malignant, benign and unspecified, were present. The ICD-9 codes for type 2 diabetes were picked specifically to include indications for type 2 diabetes without a mention of further complication.

Disease prevalence and demographic data. In this study, we identified 3,327,947 EHRs that met our inclusion criteria, of which 1,130,505 were male and 2,197,442 were female. A t-test performed between the age of males to females was found to be insignificant (Table 2 for age calculations stratified by gender). We observed a male and female combined mean age of 41.2 (+/- 12.3) years for records with an indication of headache, 43.2 (+/- 12.6) years for anxiety, a decade later at 52.2 (+/- 9.5) years for records with hypertension, and 52.9 (+/- 9.9) years for type 2 diabetes. We also observed a mean age of 41.6 (+/- 11.8) years for headache with an anxiety disorder, 46.6 (+/- 10.3) years for a headache with a hypertension disorder, and 49.7 (+/- 10.0) years for headache and type 2 diabetes.

The joint observation between disease and headache. The estimated OR for a risk of headache in records with an indication of anxiety disorder, hypertension, or type 2 diabetes was calculated using conditional logistic regression with a 95 % CI (Table 3). For each case (tested comorbidity with headache indication) two controls (disease with no headache indication) were randomly identified from the sample population, matched by age and gender, followed by two additional CLR calculations over each gender cohort whilst matching for age only. We observed an increased estimate of joint observation between those records with anxiety (OR = 2.87 95% CI: 2.70-3.06) or hypertension (OR = 1.86 95% CI: 1.79-1.93) and a headache indication. We observed a greater estimate in OR in both tested comorbidities, anxiety and hypertension, in the female cohort compared with the male cohort (OR Males 2.28 95% CI: 2.02 – 2.57, 1.64 95% CI: 1.54 – 1.76; OR Females 3.24 95% CI: 3.00 – 3.49, 1.95% CI: 1.87 – 2.05, respectively).

By contrast, we observed a drop in OR between those records with an indication for type 2 diabetes and an indication for headache (OR = 0.89 95% CI: 0.83-0.95), with males having lower estimated odds (0.83 95% CI: 0.75-0.93) than females (0.89 95% CI: 0.83-0.96). All estimated ORs were statistically significant ($p < 0.01$).

Conclusions

This case-control study of a large US EHR dataset presents results that suggest type 2 diabetes has a protective association on headache prevalence in male and female cohorts between 18 and 65 years of age. Our findings of a joint observation between headache and hypertension and anxiety disorders demonstrates that this dataset is in agreement with existing literature, validating our methodology.

Earlier accounts of an association between diabetes and headache have been reported¹⁴⁻²⁵, however, we present a new case-control study using an ambulatory survey curated with over thirty years of patient cases across an extensive and diverse population.

This study takes no account for some of the confounds or other concerns of conventional epidemiology. Specifically; there are fewer indications per record during the first surveyed year (1979), suggesting potential unclassified cases; it is not possible to be sure whether the observed tested co-morbidity (anxiety, hypertension, type 2 diabetes) is due to the disease itself or any prescribed medications; statistical analysis over explicit indication for migraine does not have statistical power; and, finally, there exists outdated diagnoses for vascular headache, which is considered as an outdated term and a misdiagnosis. Despite the limitations of deriving knowledge from data using this approach, the fact that our findings for the odds ratio of observing headache with an indication for either anxiety or hypertension replicate earlier studies offers strong support to our results. Further population based studies taking into account prescribed medications would be the first step in separating physiological effect from pharmacological effect. Insights into the etiological overlap between headache and type 2 diabetes might be revealed from common genetic associations between the two disorders within large, well phenotyped and genotyped cohorts such as the UK Biobank.

ICD 9 Code	Description
Headache	
307.81	Tension headache
784.0	Headache
Anxiety	
300.00	Anxiety, dissociative and somatoform disorders
300.01	Panic disorder, with agoraphobia
300.10	Hysteria, unspecified
300.11	Conversion disorder
300.12	Dissociative amnesia
300.15	Dissociative disorder or reaction, unspecified
300.16	Factitious disorder with predominantly psychological signs and symptoms
300.20	Phobia, unspecified
300.29	Other isolated or specific disorders
300.3	Obsessive-compulsive disorders
300.4	Dysthymic disorder
300.5	Neurasthenia
300.7	Hypochondriasis
300.81	Somatization disorder
300.89	Other somatoform disorders
300.9	Unspecified nonpsychotic mental disorder
300.02	Generalized anxiety disorder
300.13	Dissociative fugue
300.14	Dissociative identity disorder
300.21	Agoraphobia with panic disorder
300.09	Other anxiety states
300.22	Agoraphobia without mention of panic attack
300.6	Depersonalization disorder
300.19	Other and unspecified factitious illness
300.23	Social phobia
300.82	Undifferentiated somatoform disorder
Hypertension	
401.0	Malignant essential hypertension
401.1	Benign essential hypertension
401.9	Unspecified essential hypertension
Type II diabetes	
250.00	Diabetes mellitus without mention of complication, type II or unspecified type, not stated.
250.02	Diabetes mellitus without mention of complication, type II or unspecified type, uncontrolled.

Table 1. ICD-9 drug codes for indications pertaining to headache, anxiety, hypertension and type 2 diabetes collected over the sample population.

	Population 3,327,947	Male 1,130,505	Female 2,197,442
Headache			
Count	23,172(0.70%)	7,189 (0.64%)	15,983 (0.73%)
Age	41.2 (12.3)	41.7 (12.3)	40.3 (12.4)
Anxiety disorders			
Count	89,757 (2.70%)	31,345 (2.77%)	58,412 (2.66%)
Age	43.2 (12.6)	42.6 (12.5)	43.5 (12.7)
Hypertension disorders			
Count	407,508 (12.25%)	198,327 (17.45%)	209,181 (9.52%)
Age	52.6 (9.5)	52.6 (9.4)	52.7 (9.6)
Type 2 diabetes			
Count	170,156 (5.11%)	79,929 (7.07%)	90,227 (4.11%)
Age	52.9 (9.9)	53.6 (9.0)	52.3 (10.5)
Headache and anxiety disorders			
Count	2030	485	1545
Age	41.6 (11.8)	41.8 (11.7)	41.6 (11.8)
Headache and hypertension disorders
