Declaration

Statement 1

This thesis is being submitted in partial fulfilment of the requirements for the degree of PhD.

Statement 2

This work has not been submitted in substance for any other degree or award at this or any other university or place of learning, nor is it being submitted concurrently for any other degree or award (outside of any formal collaboration agreement between the University and a partner organisation)

Statement 3

I hereby give consent for my thesis, if accepted, to be available in the University’s Open Access repository (or, where approved, to be available in the University’s library and for inter-library loan), and for the title and summary to be made available to outside organisations, subject to the expiry of a University-approved bar on access if applicable.

Declaration

This thesis is the result of my own independent work, except where otherwise stated, and the views expressed are my own. Other sources are acknowledged by explicit references. The thesis has not been edited by a third party beyond what is permitted by Cardiff University’s Use of Third Party Editors by Research Degree Students Procedure.

Acknowledgements

Firstly, I would like to express gratitude to my PhD supervisors Marco Marletta and Jonathan Ben-Artzi. Our regular meetings were both enjoyable and fundamental for my development as a mathematician. I would like to also thank them for reading through large parts of the thesis, especially Chapter 1, and providing helpful feedback. I owe a big thanks to the examiners Simon Chandler-Wilde and Mikhail Cherdantsev for their time in carefully reading my manuscript, as well as for their useful feedback and some interesting discussions. During my PhD I have had the pleasure of engaging in many stimulating mathematical discussions. In particular, I would like to thank Sabine Bögli, Matteo Capoferri, Jean-Claude Cuenin, Francesco Ferraresso, Bertrand Gauthier, Raffaele Grande, Anders Hansen and Michael Hinz. I am especially grateful to my co-authors Leonid Golinskii and Frank Rösler for their dedication to our joint ventures, as well as for sharing their wisdom. On a personal level, I thank my parents for supporting and encouraging me throughout my education, as well teaching me the importance of hard work and perseverance. Finally, I would like to thank my fiancée Laura for her enduring love, care and support.
Abstract

In this thesis, we study the spectrum of Schrödinger operators with complex potentials and Dirichlet Laplace operators on domains with rough boundaries. The focus is on spectral approximation results and a-priori bounds for the location and distribution of eigenvalues. Chapter 1 provides an overview of our main results and Chapters 2 - 5 are based on the papers [130, 129, 79, 121] respectively.

In Chapter 2, spectral inclusion and pollution results are proved for sequences of linear operators of the form $T_0 + i\gamma s_n$ on a Hilbert space, where $s_n$ is strongly convergent to the identity operator and $\gamma > 0$. We work in both an abstract setting and a more concrete Sturm-Liouville framework. The results provide rigorous justification for a method of computing eigenvalues in spectral gaps.

In Chapter 3, we consider Schrödinger operators of the form $H_R = -\frac{d^2}{dx^2} + q + i\gamma \chi_{[0,R]}$ for large $R > 0$, where $q \in L^1(0,\infty)$ and $\gamma > 0$. Bounds for the maximum magnitude of an eigenvalue and for the number of eigenvalues are proved. These bounds complement existing general bounds applied to this operator, for sufficiently large $R$.

In Chapter 4, we prove upper and lower bounds for sums of eigenvalues of Lieb–Thirring type for non-self-adjoint Schrödinger operators on the half-line. The upper bounds are established for general classes of integrable potentials and are shown to be optimal in various senses by proving the lower bounds for specific potentials. We consider sums that correspond to both the critical and non-critical cases.

In Chapter 5, we prove a Mosco convergence theorem for $H^1_0$ spaces of bounded Euclidean domains satisfying a set of mild geometric hypotheses. For bounded domains, this notion implies norm-resolvent convergence for the Dirichlet Laplacian which in turn ensures spectral convergence. A key element of the proof is the development of a novel, explicit Poincaré-type inequality. These results allow us to construct a universal algorithm capable of computing the eigenvalues of the Dirichlet Laplacian on a wide class of rough domains. Many domains with fractal boundaries, such as the Koch snowflake and certain filled Julia sets, are included among this class. Conversely, we construct a counter example showing that there does not exist a universal algorithm of the same type capable of computing the eigenvalues of the Dirichlet Laplacian on an arbitrary bounded domain.

Chapter 1

Introduction

The spectral theory of differential operators plays a crucial role in the study of ordinary and partial differential equations, which are ubiquitous in the mathematical study of science and engineering. In this thesis, we approach this topic from two viewpoints. On one hand, we prove spectral approximation results, which rigorously justify algorithms for the numerical computation of spectra. On the other hand, we prove various bounds which give us a-priori information on the location and distribution of eigenvalues, without the need for any computation.

Spectral theory is a topic with a rich history, with the self-adjoint theory being particularly developed. Throughout much of this thesis, we work with non-self-adjoint operators, which present new challenges. We also address issues of a different nature, caused by the presence of rough geometries, for instance fractal boundaries.

This chapter is devoted to giving an overview of the results in the remaining chapters. The focus is on providing a clear exposition and we do not shy away from stating our results with less than full generality in order to improve the clarity of exposition. Note that the remaining chapters may be read independently of this chapter, and of each other.

**Theorem 1.0.** In this chapter, the main results are underlined like this.

**Structure of chapter**

**Section 1.1:** We present a detailed analysis of certain non-self-adjoint perturbations called dissipative barriers. Such perturbations have the curious property that they may induce eigenvalues accumulating to an approximate copy of the spectrum shifted in the complex plane, and have applications to numerical computation of spectra. The main results are: Theorems 1.6, 1.8, 1.10, 1.11, 1.12.

**Section 1.2:** We present bounds describing the distribution of eigenvalues of Schrödinger operators with complex potentials on the half-line. These bounds generalise the clas-
Introduction

sical Lieb-Thirring inequalities. In particular, our results illuminate the role of critical parameters in the case of non-self-adjoint operators.

The main results are: Theorems 1.13, 1.14, 1.15, 1.18, Corollaries 1.16, 1.17.

**Section 1.3:** Motivated by problems on the computational complexity of the eigenvalue problem, we present spectral approximation results for the Dirichlet Laplacian on rough domains. In particular, this involves establishing a new Poincaré-type inequality. The main results are: Theorems 1.20, 1.22.

**Notation and conventions**

Let $\mathcal{H}$ be a separable Hilbert space with corresponding inner product $\langle \cdot, \cdot \rangle$ and norm $\| \cdot \|$. The domain and spectrum of a linear operator $T$ on $\mathcal{H}$ is denoted by $D(T)$ and $\sigma(T)$ respectively.

For bounded operators $B_n$, $n \in \mathbb{N}$, and $B$ on $\mathcal{H}$, recall that strong convergence, denoted by $B_n \xrightarrow{s} B$ as $n \to \infty$, is said to hold if $B_n f \to B f$ as $n \to \infty$ for every $f \in \mathcal{H}$. For $f_n \in \mathcal{H}$, $n \in \mathbb{N}$, and $f \in \mathcal{H}$, recall that weak convergence, denoted by $f_n \rightharpoonup f$ as $n \to \infty$, is said to hold if $\langle f_n, g \rangle \to \langle f, g \rangle$ as $n \to \infty$ for every $g \in \mathcal{H}$.

In this thesis, we define the essential spectrum of an operator $T$ on $\mathcal{H}$ by

$$\sigma_e(T) = \left\{ \lambda \in \mathbb{C} : \exists (u_n) \subset D(T) \text{ with } \|u_n\| = 1, u_n \rightharpoonup 0, \|(T - \lambda)u_n\| \to 0 \right\}$$  \hspace{1cm} (1.1)

which corresponds to $\sigma_{e2}$ in [61]$^1$. The sequence $(u_n)$ appearing in (1.1) is referred to as a singular sequence. Furthermore, the set of isolated eigenvalues of finite algebraic multiplicity$^2$ is referred to as the discrete spectrum and is denoted by $\sigma_d(T)$. Note the geometric multiplicity of an eigenvalue (i.e. the dimension of the eigenspace) never exceeds the algebraic multiplicity.

We adopt the convention that $\mathbb{R}_+ = [0, \infty) = \{ x \in \mathbb{R} : x \geq 0 \}$. $\mathbb{R}_{>0}$, $\mathbb{R}_{\leq 0}$, etc. are defined similarly. The convention we take with regards to the square-root function is to make the branch-cut along $\mathbb{R}_+$, so that $\text{Im} \sqrt{z} \geq 0$ for all $z \in \mathbb{C}$. Finally, $B_X(0)$ denotes an open ball of radius $X$ about the origin in $\mathbb{C}$ or $\mathbb{R}^2$.

---

$^1$In fact, for non-self-adjoint operators there are at least five non-equivalent conventions for the definition of essential spectrum, which all coincide for self-adjoint operators [61, Theorem 1.6].

$^2$The algebraic multiplicity of an eigenvalue is defined as the dimension of the image of the corresponding Riesz spectral projection [93, eqn. 2.47].
1.1 Dissipative barriers

In this section, we study a class of non-self-adjoint perturbations which we call dissipative barriers. In their most general form, the perturbed operators we consider take the form

\[ T_n = T_0 + i\gamma s_n, \quad n \in \mathbb{N}, \]  

(1.2)

where \( T_0 \) is an unbounded operator on a Hilbert space \( \mathcal{H} \), \( \gamma > 0 \) is regarded as a fixed parameter and \( s_n \) is a sequence of bounded, \( T_0 \)-compact operators (see [61, Chapter III, Definition 7.3]) such that \( s_n \to I \) strongly as \( n \to \infty \). In addition, we pay particular attention to the model case of Schrödinger operators on \( L^2(\mathbb{R}_+) \) perturbed by a “discontinuous” dissipative barriers,

\[ H_R = H_0 + i\gamma \chi_{[0,R]} = -\frac{d^2}{dx^2} + q + i\gamma \chi_{[0,R]}, \quad R > 0, \]  

(1.3)

where \( q \) is a fixed multiplication operator referred to as a background potential, \( \chi \) denotes the indicator function and \( \gamma > 0 \) is a fixed parameter.

Our results shall require additional assumptions, which shall be stated as we go along. For instance, the abstract result Theorem 1.8 holds for the case that \( T_0 \) is self-adjoint. For Schrödinger operators \( H_0 \), we also deal with non-self-adjoint operators \( H_0 \) (i.e. complex potentials \( q \)). In this case, we shall require other assumptions on \( q \) such as integrability or reality and periodicity outside a compact interval, which allows for the application of technical tools such that Levinson’s asymptotical theorem or Floquet theory (resp.).

A key property of dissipative barrier perturbations is that they leave the essential spectrum invariant. Assume that \( T_0 \) and \( H_0 \) are closed [61, pg. 95]. By the relative compactness of the dissipative barrier perturbations \( i\gamma s_n \) and \( i\gamma \chi_{[0,R]} \), Weyl’s theorem guarantees that

\[ \sigma_e(T_n) = \sigma_e(T_0) \quad \text{and} \quad \sigma_e(H_R) = \sigma_e(H_0), \]  

(1.4)

respectively (see [61, Chapter IX, Theorem 2.1]).

One of our key results on dissipative barriers states that, under suitable hypotheses on \( q \), for any point in the spectrum \( \mu \in \sigma(H_0) \), \( \mu + i\gamma \) is approximated by eigenvalues \( \lambda_R(\mu) \in \sigma_d(H_R) \), in the sense that

\[ \lambda_R(\mu) \to \mu + i\gamma \quad \text{as} \quad R \to \infty. \]
In other words, for large $R$, the dissipative barrier $i\gamma \chi_{[0,R]}$ generates an approximate “copy” of the spectrum shifted by $i\gamma$ in the complex plane. The importance of such results lies in the fact that, by numerically computing this “copy” of the spectrum, one may avoid problems of spurious eigenvalues (that is, spectral pollution due to numerical discretisation) that are often encountered when trying to numerically compute $\sigma(H_0)$ directly. This is explained further in Sections 1.1.1 and 1.1.2.

The rich behaviour of the eigenvalues of $H_R$ for large $R$ also makes it an interesting example in the wider context of Schrödinger operators with complex potentials. The operators $H_R$ are studied from this perspective in Chapter 3 and Section 4.3; these results are summarised below in Section 1.1.4. In particular, the special case $q \equiv 0$ is an important counter-example in the theory of Lieb–Thirring-type inequalities for non-self-adjoint Schrödinger operators and can be used as a building block in the construction of more sophisticated counter-examples (see Section 4.4).

### 1.1.1 Motivation: spectral pollution

Consider a sequence of operators $T_n$, $n \in \mathbb{N}$, intended to approximate a given limit operator $T$. A point $\mu \in \sigma(T)$ is approximated by the spectra of $T_n$ if there exists $\lambda_n(\mu) \in \sigma(T_n)$, $n$ large enough, such that

$$\lambda_n(\mu) \to \mu \quad \text{as} \quad n \to \infty.$$ 

Even if every point in $\sigma(T)$ is approximated by the spectra of $T_n$, we cannot conclude that $\sigma(T_n)$ is a good approximation for $\sigma(T)$ as $n \to \infty$; one must also ensure that there is no spectral pollution. The formal definition of spectral pollution is as follows.

**Definition 1.1.** $\mu \in \mathbb{C}$ belongs to the the set of *spectral pollution* of $(T_n)_{n \in \mathbb{N}}$ with respect to $T$ if it lies in the resolvent set $\rho(T) = \mathbb{C} \setminus \sigma(T)$ and there exists a subsequence $(T_{n_k})_{k \in \mathbb{N}} \subset (T_n)_{n \in \mathbb{N}}$ along with spectral points $\lambda_{n_k}(\mu) \in \sigma(T_{n_k})$, $k \in \mathbb{N}$, such that

$$\lambda_{n_k}(\mu) \to \mu \quad \text{as} \quad k \to \infty.$$ 

Spectral pollution is known to cause serious issues for the numerical computations of spectra, particularly when the operator in question has essential spectrum with band gap structure (see [84, Figure 8] for instance). Let us look at a basic example of this phenomenon, which motivates the results presented below.
Consider a Schrödinger operator on the half-line endowed with a mixed boundary condition at 0, with Robin parameter $\eta \in [0, \pi)$,

$$H_0u = -u'' + qu,$$

$$u \in D(H_0) = \{u \in L^2(\mathbb{R}^+) : u, u' \in AC_{\text{loc}}[0, \infty), -u'' + qu \in L^2(\mathbb{R}^+) \}.$$

(1.5)

Assume that $q$ is real-valued, locally integrable in $[0, \infty)$ and eventually periodic, that is, there exists $A_0, a > 0$ such that

$$\forall x > A_0 : q(x + a) = q(x).$$

(1.6)

These assumptions allow for the application of the powerful tools of Floquet theory and ensure that $H_0$ is self-adjoint$^3$.

Typically, $\sigma_e(H_0)$ may have a band gap structure and $H_0$ may have eigenvalues in the spectral gaps. For this reason, this operator is an ideal model for investigating spectral pollution in differential operators, and methods to overcome it.

In order to directly numerically discretise $H_0$ with a finite-difference or Galerkin method, the first step is to perform a domain truncation. The simplest truncated Schrödinger operators $H_{0,X}, X > 0$, take the form

$$H_{0,X}u = -u'' + qu, \quad u \in D(H_{0,X}) = \{u|_{[0,X]} : u \in D(H_0), u(X) = 0 \}.$$

That is, we impose an artificial Dirichlet boundary condition at $X$. For each $X > 0$, $H_{0,X}$ is self-adjoint and has a purely discrete spectrum which can generally be reliably numerically computed [115].

The truncated operators $H_{0,X}$ approximate the limit operator $H_0$ in the strong sense and in fact in the strong resolvent sense$^4$ [7]. Invoking the self-adjointness of $H_0$ and $H_{0,X}$, classical results tell us that therefore every point in the spectrum of $H_0$ is approximated by the eigenvalues of $H_{0,X}$ [118, Chapter VIII.7]. This is formulated precisely as follows.

**Proposition 1.2.** Let $(X_n)_{n \in \mathbb{N}} \subset \mathbb{R}^+$ such that $X_n \to \infty$ as $n \to \infty$. Then, for every $\mu \in \sigma(H_0)$, there exists a sequence of eigenvalues $\lambda_n(\mu) \in \sigma_d(H_{0,X_n}), n \in \mathbb{N}$, such that $\lambda_n(\mu) \to \mu$ as $n \to \infty$.

If the essential spectrum of $H_0$ is non-empty with a band structure, it is not hard to show that the simple domain procedure described above produces spectral pollution.

$^3$Note that self-adjointness also holds for a much wider class of real potentials.

$^4$That is, $(H_{0,X} - \lambda)^{-1} \to (H_0 - \lambda)^{-1}$ as $X \to \infty$ for any $\lambda \in \mathbb{C} \setminus \mathbb{R}$. 
This renders the spectral approximation of $H_0$ with the operators $H_{0,X}$ unreliable in general.

**Proposition 1.3.** Assume that there exists $-\infty < a < b < \infty$ such that $[a, b] \subset \sigma_e(H_0)$. Then for any $\mu > b$ there exists an arbitrarily large $X > 0$ such that $\mu \in \sigma_d(H_{0,X})$.

**Corollary 1.4.** In addition to the hypotheses of Proposition 1.3, assume that at least one point in $(b, \infty)$ lies in the resolvent set $\rho(H_0)$. Then there exist $(X_n)_{n \in \mathbb{N}} \subset \mathbb{R}_+$ with $\lim_{n \to \infty} X_n = \infty$ such that the set of spectral pollution of $(H_{0,X_n})_{n \in \mathbb{N}}$ with respect to $H_0$ is non-empty.

Now, consider a perturbation of $H_0$ by a dissipative barrier and its truncation,

$$H_R := H_0 + i\gamma \chi_{[0,R]}, \quad H_{R,X} := H_{0,X} + i\gamma \chi_{[0,R]}, \quad R, X > 0. \quad (1.7)$$

In [104], Marletta and Scheichl have shown that, not only may the eigenvalues of $H_R$ be rapidly approximated using domain truncation methods, but in fact any spectral pollution incurred must lie on the real line.

**Theorem 1.5 ([104, Theorems 5 and 6]).** For any eigenvalue $\mu_R$ of $H_R$, there exists $X_0 > 0$, eigenvalues $\lambda_{R,X}$ of $H_{R,X}$, $X > X_0$, and $C_1, C_2 > 0$ such that

$$|\mu_R - \lambda_{R,X}| \leq C_1 \exp(-C_2X), \quad \text{for all} \quad X > X_0.$$

Furthermore, for any compact set $K \subset \rho(H_R) \setminus \mathbb{R}$, there exists $X_K > 0$ such that

$$\sigma(H_{R,X}) \cap K = \emptyset \quad \text{for all} \quad X > X_K.$$

Let $\lambda \in \mathbb{C}$ be an eigenvalue of $H_R$ with corresponding $L^2$-normalised eigenfunction $u$. Multiplying both sides of the eigenvalue equation by $\overline{u}$ and integrating by parts, we have

$$\int_0^\infty |u'(x)|^2 \, dx + \int_0^\infty q(x)|u(x)|^2 \, dx + i\gamma \int_0^R |u(x)|^2 \, dx = \lambda \int_0^\infty |u(x)|^2 \, dx = \lambda.$$

Taking the imaginary part of both sides of the above equality, noting that $q$ is real-valued, we obtain

$$\text{Im} \lambda = i\gamma \int_0^R |u(x)|^2 \, dx > 0.$$

---

5Proof. For any $X > 0$, let $\lambda_n(H_X)$ denote the $n$th eigenvalue of $H_{0,X}$. Let $X_0 > 0$. Since the eigenvalues of $H_{0,X_0}$ accumulate at $+\infty$ there exists $n \in \mathbb{N}$ such that the $\lambda_n(H_{0,X_0}) > \mu$. By the hypothesis and Proposition 1.2, there exists $X_1 > X_0$ such that $\lambda_n(H_{0,X_1}) < b < \mu$. The result follows from the continuity of $X \mapsto \lambda_n(H_{0,X})$ [89, Th. 3.1].
1.1 Dissipative barriers

We conclude that all eigenvalues of $H_R$ lie strictly away from the real-line. Consequently, Theorem 1.5 effectively demonstrates that the eigenvalues may be reliably computed.

1.1.2 Dissipative Barrier Method

The dissipative barrier method is a strategy to avoid problems of spectral pollution in the numerical computation for a self-adjoint operator $H_0$. The discussion in the previous section brings us to the main idea of this method, which may be summarised as follows.

1. Approximate $\sigma(H_0) + i\gamma$ by the eigenvalues of $H_R$.
2. Numerically approximate the eigenvalues of $H_R$.

In this way, we could numerically approximate $\sigma(H_0) + i\gamma$ (at least in a compact subset of $\mathbb{C}$), from which a numerical approximation of $\sigma(H_0)$ may be immediately recovered. We focus entirely on Step 1, that is, the spectral approximation of the limit operator $H_0 + i\gamma$ by the perturbed operators $H_R$ for large $R$. This is poorly understood compared to Step 2, which has been justified by various results, such as Theorem 1.5.

Let us now present our first result. In the following theorem, and throughout this subsection, $H_R$ denotes perturbed Schrödinger operators on the half line with eventually periodic background potential $q$, as defined by (1.5), (1.6) and (1.7).

**Theorem 1.6** (Theorems 2.23 and 2.33). For any eigenvalue $\mu_d$ of $\sigma_d(H_0)$, there exists $R_1 > 0$, eigenvalues $\lambda_R(\mu_d) \in \sigma_d(H_R)$, $R > R_1$, and $C_1, C_2 > 0$ such that

$$|\mu_d + i\gamma - \lambda_R(\mu_d)| \leq C_1 \exp(-C_2 R) \quad \text{for all} \quad R > R_1.$$

Furthermore, for any $\mu_e \in \sigma_e(H_0)$, there exists $R_2 > 0$ and eigenvalues $\lambda_R(\mu_e) \in \sigma_d(H_R)$, $R > R_2$, such that

$$\lambda_R(\mu_e) \to \mu_e + i\gamma \quad \text{as} \quad R \to \infty.$$

For $\mu_e \in \sigma_e(H_0)$ lying outside of a certain set of isolated points corresponding to the embedded resonances of $H_0$ (see Definition 2.36), there exists $C_3 > 0$ such that

$$|\mu_e + i\gamma - \lambda_R(\mu_e)| \leq \frac{C_3}{R} \quad \text{for all} \quad R > R_2.$$  \hspace{1cm} (1.8)

**Remark 1.7.** In Chapter 2, this result is formulated in a more general way and we also treat background potentials satisfying other hypotheses. For the special case $q(x) = 0,$
Introduction

$x > A_0$, an analogous result has been proven in [55]. The approximation of shifted eigenvalues $\sigma_d(H_0) + i\gamma$ has been partially treated in [104] and [84], although their results do not fully cover the first part of the above theorem (and certainly do not cover the second).

Figure 1.1 illustrates the effect of adding a dissipative barrier to a real, eventually periodic background potential. Note that the eigenvalues in this figure are in fact numerically computed\(^6\).

**Figure 1.1** The effect of adding a dissipative barrier.

**Embedded resonances.** In Theorem 1.6, we do not have a rate of convergence for points $\mu_e + i\gamma$, where $\mu_e \in \sigma_e(H_0)$ is an embedded resonance. As explained in Remark 2.37, the eigenvalues of $H_0$ can be expressed as the zeros of a certain analytic function. This function admits an analytic continuation past the essential spectrum $\sigma_e(H_0)$, revealing new zeros which we refer to as resonances. Embedded resonances are those lying exactly on $\sigma_e(H_0)$. Interestingly, numerical evidence indicates that the eigenvalues of $H_R$ behave in an exceptional way near shifted embedded resonances (see Figure 2.3).

\(^6\)For $q(x) = -10\chi_{[0,5]}(x) + \sum_{n=0}^{\infty} 20\chi_{[0,8,1]}(x - n)$. $\gamma = 30$ and $R = 40$. 
1.1 Dissipative barriers

**Spectral pollution.** Note that Theorem 1.6 does not say anything about spectral pollution incurred by the dissipative barrier, that is, the set of spectral pollution of \((H_{R_n})_{n \in \mathbb{N}}\) with respect to \(H_0 + i\gamma\), for sequences \((R_n)_{n \in \mathbb{N}} \subset \mathbb{R}_+\). Since \(\sigma_e(H_0)\) is a subset of \(\sigma(H_R)\) for all \(R\), it belongs to this set of spectral pollution, for any \((R_n)_{n \in \mathbb{N}}\).

In Chapter 2, we construct an analytic function whose zero set encloses any point of spectral pollution outside of \(\sigma_e(H_0)\) (for the case that \(R_n - R_{n-1} = a\)). Numerical evidence suggests that, in general, there may be spectral pollution outside \(\sigma_e(H_0)\) (see Figure 2.4).

### 1.1.3 Abstract results

One appealing aspect of the dissipative barrier method is that the ideas apply to very general classes of operators. Throughout this subsection, we consider a sequence of operators

\[
T_n = T_0 + i\gamma s_n, \quad n \in \mathbb{N},
\]

on a separable Hilbert space, where \(\gamma > 0\) is fixed. We assume that

\[
T_0 \text{ is self-adjoint, } s_n \rightharpoonup I \text{ as } n \to \infty \text{ and } \sup_{n \in \mathbb{N}} ||s_n|| < \infty. \tag{1.10}
\]

The next result states that the shifted eigenvalues \(\sigma_d(T_0) + i\gamma\) are approximated by the eigenvalues of \(T_n\) as \(n \to \infty\) for two classes of barrier operators \(s_n\). Furthermore, enclosures are provided for the set of spectral pollution induced by such perturbations. It is proven in Section 2.2 by utilising the notion of *limiting essential spectrum* for unbounded operators [18].

**Theorem 1.8** (Theorem 2.12). Assume that the operators defined by (1.9) and (1.10) satisfy one of the following hypotheses.

(a) \(s_n\) is a projection operator for all \(n\), that is, \(s_n^2 = s_n\). In this case, let

\[
\Gamma_a := \left\{ \lambda \in \mathbb{C} : \text{Im(}\lambda\text{)} \in [0, \gamma], \text{dist}(\text{Re(}\lambda\text{)}, \sigma_e(T_0)) \leq \sqrt{\text{Im(}\lambda\text{)(}\gamma - \text{Im(}\lambda\text{))}} \right\}.
\]

(b) For any sequence \((u_n)_{n \in \mathbb{N}} \subset D(T_0)\) with \(\sup_n ||u_n|| < \infty\) and \(\sup_n ||T_0u_n|| < \infty\), we have

\[
\langle s_nu_n, T_0u_n \rangle - \langle T_0u_n, s_nu_n \rangle \to 0 \text{ as } n \to \infty.
\]

In this case, let

\[
\Gamma_b := \sigma_e(T_0) + i[0, \gamma].
\]
Then, for any $\mu \in \sigma_d(T_0)$, there exists $n_0 \in \mathbb{N}$ and eigenvalues $\lambda_n(\mu) \in \sigma_d(T_n)$, $n \geq n_0$ such that

$$\lambda_n(\mu) \to \mu + i\gamma \quad \text{as} \quad n \to \infty.$$ 

Furthermore, the set of spectral pollution of $(T_n)_{n \in \mathbb{N}}$ with respect to $T_0 + i\gamma$ is contained in $\Gamma_a$ or $\Gamma_b$ respectively.

Both hypotheses (a) and (b) can be verified in a variety of interesting concrete settings, for instance, partial differential operators and infinite matrices. For the case of operators on $L^2(\mathbb{R}^+)$, “barrier” operators $s_n$ satisfying these hypotheses can be constructed as follows.

**Example 1.9.** (a) Let $s_n$ be a multiplication operator on $L^2(\mathbb{R}^+)$ defined for any $u \in L^2(\mathbb{R}^+)$ by

$$(s_n u)(x) = \chi_{[0,n]}(x)u(x), \quad x \in \mathbb{R}^+.$$ 

Then $s_n$ satisfies hypothesis (a) of Theorem 1.8.
1.1 Dissipative barriers

(b) Let \( \varphi : \mathbb{R}_+ \to [0, 1] \) be any smooth function such that \( \text{supp} \varphi \subset [0, 1] \) and \( \varphi \equiv 1 \) on \([0, \frac{1}{2}]\). Let \( s_n \) be a multiplication operator on \( L^2(\mathbb{R}_+) \) defined for any \( u \in L^2(\mathbb{R}_+) \) by

\[
(s_n u)(x) = \varphi(x/n)u(x), \quad x \in \mathbb{R}_+.
\]

Then, \( s_n \) satisfies hypothesis (b) of Theorem 1.8.

A consequence of Theorem 1.8 is that, any eigenvalue of \( T_n \) outside of \( \Gamma_a \) or \( \Gamma_b \) must be near to an eigenvalue of \( T_0 + i\gamma \) for large \( n \), or more precisely,

\[
\forall \varepsilon > 0 : \exists n_0 \in \mathbb{N} : \forall n \geq n_0 : \forall \lambda_n \in \sigma_d(T_n) \cap \Gamma^c : \text{dist}(\lambda_n, \sigma_d(T_0) + i\gamma) < \varepsilon \quad (1.11)
\]

where \( \Gamma = \Gamma_a \) or \( \Gamma_b \) respectively. Returning to the numerical analysis point of view, suppose that we know the essential spectrum \( \sigma_e(T_0) \). In this case, we could compute \( \Gamma_a \) or \( \Gamma_b \), and restrict our attention to the eigenvalues of \( T_n \) in \( \mathbb{C} \setminus \Gamma \). Then (1.11) indicates that these eigenvalues can be taken as an approximation for the shifted discrete spectrum \( \sigma_d(H_0) + i\gamma \).

1.1.4 Eigenvalue bounds

**Spectral enclosures.** Any eigenvalue \( \lambda \) of a Dirichlet Schrödinger operator on the half-line with a complex-valued potential \( q \in L^1(\mathbb{R}_+) \) (i.e. the operator (1.20)) is contained in a closed ball of radius \( \|q\|_{L^1}^2 \),

\[
|\lambda|^{1/2} \leq \|q\|_{L^1}. \quad (1.12)
\]

This inequality may be shown to be sharp\(^7\) by, essentially, considering a potential of the form \( q(x) = c\delta(x - b) \), where \( c \in \mathbb{C}, b \in \mathbb{R} \) and \( \delta \) is the Dirac delta distribution [69, Theorem 1.1].

Now consider a Dirichlet Schrödinger operator of the form

\[
H_R = -\frac{d^2}{dx^2} + q + i\gamma \chi_{[0,R]} \quad \text{on} \quad L^2(\mathbb{R}_+) \quad (1.13)
\]

where \( q \in L^1(\mathbb{R}_+) \) may be complex-valued, \( \gamma > 0 \). Informally speaking, a potential that can be decomposed into the form \( q + i\gamma \chi_{[0,R]} \) for large \( R \) looks very different from a Dirac delta distribution, in the sense that its mass is spread over a large region. This raises the question:

\(^7\)In fact (1.12) can be improved to \( |\lambda|^{1/2} \leq g(\theta)\|q\|_{L^1} \) where \( g(\theta) \) is a function depending on the complex argument \( \theta \) of \( \lambda \), and taking values in \([1/2,1]\).
Q: Does (1.12) (with $q$ replaced by $q + i\gamma \chi_{[0,R]}$) give a good enclosure for the eigenvalues of $H_R$ for large $R$? Can it be improved for this case?

Asymptotically, (1.12) gives the estimate $|\lambda_R|^{1/2} = O(R)$ as $R \to \infty$. Our next result not only gives a logarithmic improvement for this estimate, but also states that eigenvalues of $H_R$ are bounded independently of $R$ along any ray other than $\mathbb{R}_+$.

**Theorem 1.10** (Theorem 3.4). There exists $X = X(\gamma, q) > 0$ such that

$$\sigma_d(H_R) \subset B_X(0) \cup \Gamma_{\gamma},$$

where $H_R$ refers to the operator (1.13) and

$$\Gamma_{\gamma} := (0, \infty) + i(0, \gamma).$$

Furthermore, there exists $R_0 = R_0(\gamma, q) > 0$ such that any eigenvalue $\lambda$ of $H_R$, $R \geq R_0$, satisfies

$$|\lambda - i\gamma|^{1/2} \leq \frac{5\gamma R}{\log R}. \quad (1.14)$$

![Figure 1.4 An illustration of the spectral enclosure provided by Theorem 1.10.](image)

**Number of eigenvalues.** Now consider the case that the background potential $q$ satisfies one of the following two assumptions:

(i) $q$ is compactly supported,

(ii) (Naimark condition) There exists $c > 0$ such that

$$\int_0^\infty e^{cx} |q(x)| \, dx < \infty. \quad (1.15)$$
1.1 Dissipative barriers

Note that first condition is stronger, since compactly supported potentials satisfy the Naimark condition, and we obtain stronger results for this case accordingly.

By a classical result of Naimark [108], if the background potential satisfies assumption (i) or (ii) above, then the number of eigenvalues (counting algebraic multiplicities) $N(H_R)$ of $H_R$ is finite.

In Section 2.4, we prove that, under assumption (i) or (ii) above, every point in $i\gamma + \mathbb{R}_+$ is approximated by the eigenvalues of $H_R$. As a consequence, it must hold that

$$N(H_R) \to \infty \quad \text{as} \quad R \to \infty.$$ 

A natural question to ask is:

Q: How fast does $N(H_R)$ tend to $\infty$?

We first address upper bounds for $N(H_R)$. A lower bound shall later be also provided for the case $q \equiv 0$.

In [68], Frank, Laptev and Safronov provided a quantitative upper bound for the number of eigenvalues of Schrödinger operators with potentials satisfying the Naimark condition. It is shown in Section 3.1 that, applied to perturbed operators $H_R$ such that $q$ satisfies the Naimark condition, their result gives the asymptotic estimate

$$N(H_R) = O(R^4) \quad \text{as} \quad R \to \infty.$$ 

More recently, Korotyaev has proven a bound specific to compactly supported potentials [90]. This bound gives an improved asymptotic bound for perturbed operators $H_R$ such that $q$ is compactly supported,

$$N(H_R) = O(R^2) \quad \text{as} \quad R \to \infty.$$ 

Note that this asymptotic improvement extends beyond operators of the specific form $H_R$ to more general semiclassical Schrödinger operators with compactly supported potentials (such operators are considered in Remark 4.10 for instance). The next result shows that further improvements are possible for the operators $H_R$, even when the background potential is not compactly supported (in which case Korotyaev’s result does not apply).

**Theorem 1.11** (Theorems 3.10 and 3.14). Consider the perturbed Dirichlet Schrödinger operator (1.13) with a background potential $q \in L^1(\mathbb{R}_+)$ and $\gamma > 0$. 

(a) If \( q \) is compactly supported, then there exists \( R_0 = R_0(q, \gamma) > 0 \) such that
\[
N(H_R) \leq \frac{11 \gamma R^2}{\log 2 \log R}, \quad R \geq R_0.
\]

(b) If \( q \) satisfies the Naimark condition, then there exists \( R_0 = R_0(q, \gamma) > 0 \) such that
\[
N(H_R) \leq 10^5 \frac{\sqrt{X} + c}{c^2} \frac{\gamma^2 R^3}{(\log R)^2}, \quad R \geq R_0,
\]
where \( X > 0 \) is the constant from Theorem 1.10 and \( c > 0 \) is the constant appearing in (1.15).

While the above bound (a) is based on an application of Jensen’s formula, the proof of (b) involves proving a customised complex analysis estimate (see Proposition 3.12) adapted to the problem at hand. It is possible that elements of the proof could be useful in the future to prove more general bounds for the number of eigenvalues of Schrödinger operators. An interesting feature of both bounds (a) and (b) is the logarithmic improvement, which happens to come directly from the logarithm in the magnitude bound (1.14).

Free barrier. In the case of trivial background potential \( q \equiv 0 \), we denote the perturbed Dirichlet Schrödinger operators \( H_R \) studied above as
\[
L_{\gamma,R} := -\frac{d^2}{dx^2} + i\gamma \chi_{[0,R]}, \quad \gamma, R > 0.
\]
Despite its simplicity, this family of operators is at the centre of a variety of crucial counter-examples in the theory of Lieb-Thirring-type inequalities. Such counter examples are studied in Chapter 4 and discussed in Section 1.2.

Compared to upper bounds such as Theorems 1.10 and 1.11, lower bounds for properties of the eigenvalues (e.g. the maximum magnitude) are often harder to prove. This is due to the requirement of proving existence of complex eigenvalues with given properties. This is especially true in the case of lower bounds for the number of eigenvalues, or sums of eigenvalues, where we are required to prove the existence of large families of eigenvalues.

The next result allows us to prove such lower bounds for \( L_{\gamma,R} \). Let \( \sqrt{z} \) denote the branch of the square root function such that \( \text{Im} \sqrt{z} > 0 \) for \( z \in \mathbb{C} \setminus \mathbb{R}_- \).
Theorem 1.12 (Proposition 4.16 and Lemma 4.17). Suppose that $R \geq 600(\gamma^{3/4} + \gamma^{-3/4})$. Then there exist distinct eigenvalues

$$\lambda_j \in \sigma_d(L_{\gamma,R}), \quad 1 \leq j \leq \left\lfloor \frac{1}{32\pi \log R} \right\rfloor,$$

which satisfy

$$\Re(\lambda_j) \geq 0, \quad \frac{\gamma}{2} \leq \Im(\lambda_j) \leq \gamma$$

and

$$\sqrt{\lambda_j - i\gamma} = \frac{i}{2R} \left[ \log \left( \frac{\sqrt{\lambda_j - i\gamma} - \sqrt{\lambda_j}}{\sqrt{\lambda_j - i\gamma} + \sqrt{\lambda_j}} \right) + 2\pi i j \right]. \tag{1.17}$$

An immediate consequence of this is that there exists $C > 0$ such that for all large enough $R$,

$$N(L_{\gamma,R}) \geq C \frac{R^2}{\log R}; \quad (1.18)$$

This demonstrates that Theorem 1.11 (a) gives an order sharp large $R$ estimate.

Although (1.17) is not explicitly resolved in terms of $\lambda_j$, it still gives detailed information about the location of the individual eigenvalues $\lambda_j$ since the logarithm term can often be effectively estimated. A consequence of Theorem 1.12 is Proposition 4.19, which implies that there exists $C > 0$ such that for all large enough $R$,

$$\sup_{\lambda \in \sigma_d(L_{\gamma,R})} |\lambda|^{1/2} \geq C \frac{R}{\log R}, \tag{1.19}$$

proving that inequality (1.14) in Theorem 1.10 gives an order sharp large $R$ estimate.

1.2 Critical case Lieb–Thirring inequalities

Schrödinger operators with real-valued potentials form the central object in non-relativistic quantum mechanics. When the potentials are allowed to be complex, the theory drastically changes since the operators become non-self-adjoint. As well as the applications in numerical analysis described in the previous section, complex potentials appear in the study of systems with energy loss or gain, such as open quantum systems and the damped wave equation [63, 126].

In this section, we give an overview of the results of Chapter 4, which describe the eigenvalues of Dirichlet Schrödinger operators on the half-line with complex potentials $q \in L^1(\mathbb{R}_+)$,

$$H_q u = -u'' + qu, \quad u \in D(H_q) = \{ u \in H^1_0(\mathbb{R}_+) : -u'' + qu \in L^2(\mathbb{R}_+) \}. \tag{1.20}$$
For such operators, we have $\sigma_e(H_q) = [0, \infty)$ and the spectrum may be decomposed as

$$\sigma(H_q) = \{\lambda_n\}_{n=1}^N \cup [0, \infty), \quad \text{where} \quad \lambda_n \in \sigma_d(H_q) \quad \text{satisfy} \quad |\lambda_n|^{1/2} \leq \|q\|_{L^1}$$

and $N \in \mathbb{N}_0 \cup \{\infty\}$ [69]. Note that eigenvalues of higher algebraic multiplicity are repeated accordingly in $\{\lambda_n\}_{n=1}^N$. It is known that the number of eigenvalues $N$ may be infinite, in which case the eigenvalues $\lambda_n$ must accumulate to a point in $[0, \infty)$.

We focus on studying sums of the form,

$$S_\varepsilon(H_q) := \sum_{n=1}^N \frac{\text{dist}(\lambda_n, \mathbb{R}_+)}{|\lambda_n|^{(1-\varepsilon)/2}}, \quad \varepsilon \geq 0 \quad (1.21)$$

which describe the distribution of the eigenvalues with respect to the essential spectrum $\mathbb{R}_+$ and the origin of the complex plane. Lieb-Thirring sums, and the corresponding inequalities, originally arose out of the theory of self-adjoint Schrödinger operators and quantum mechanics, where they play a crucial role in the proof of stability of matter. Here, we are concerned with generalisations for non-self-adjoint operators. Sums of this form also arise out of the complex analysis underlying the problem and represent an interesting connection between complex function theory and spectral theory. Note that our results also apply to a wider class of Lieb–Thirring sums (see Proposition 4.23).

When $q$ is real-valued, $H_q$ is self-adjoint and the isolated eigenvalues are strictly negative, $\lambda_n < 0$. In this case, the distribution of the eigenvalues is described by the classical Lieb-Thirring inequality,

$$\sum_{n=1}^N |\lambda_n|^{(1+\varepsilon)/2} \leq C(\varepsilon) \int_0^\infty q_-(x)^{1+\varepsilon} \, dx, \quad \varepsilon \geq 0 \quad (1.22)$$

where $C(\varepsilon) > 0$ and $q_-(x)$ denotes the negative part of $q(x)$. For negative eigenvalues $\lambda_n$, we have $\text{dist}(\lambda_n, \mathbb{R}_+) = |\lambda_n|$ so the sum $S_\varepsilon(H_q)$ coincides with the sums in (1.22).

In both (1.21) and (1.22), $\varepsilon = 0$ corresponds to a critical case. As shall be further explained, the isolated eigenvalues can be expressed in a very natural way as

$$\lambda_n = z_n^2, \quad z_n \in \mathbb{C}_+,$$

where $\{z_n\}_{n=1}^N$ are the zeros of a certain analytic function in the upper half plane. Then the sum $S_0(H_q)$ is equivalent to the sum

$$J(H_q) := \sum_{n=1}^N \text{Im} z_n \quad (1.23)$$
1.2 Critical case Lieb–Thirring inequalities

in the sense that $J(H_q) \leq S_0(H_q) \leq 2J(H_q)$ (see (4.8)). The sums $J(H_q)$, which we refer to as Jensen sums, arise in Jensen’s formula from complex analysis as well as in the Blaschke condition for the upper-half-plane (see Remark 4.13).

1.2.1 Main results

The novelty of the results in Chapter 4 lies in the fact that they provide a detailed description of the critical case $\epsilon = 0$ alongside the non-critical case $\epsilon > 0$, for non-self-adjoint operators. Namely, we provide upper bounds for $S_\epsilon(H_q)$ for all $\epsilon \geq 0$ and corresponding lower bounds show the optimality of the results in various senses.

Upper bound for non-critical case. Our first result is a quantitative upper bound for the sums $S_\epsilon(H_q)$ in the case $\epsilon > 0$. A key difference between our result and the classical Lieb–Thirring inequality (1.22) is that our bound is valid for complex-valued $L^1$ potentials, whereas the right hand side of (1.22) may be infinite for certain real-valued $L^1$ potentials.

**Theorem 1.13** (Theorem 4.5). For any $\epsilon > 0$, there exists $C(\epsilon) > 0$ such that

$$S_\epsilon(H_q) \leq C(\epsilon) \|q\|^{1+\epsilon}_{L^1}.$$  

For $\epsilon > 1$, this result was previously proved by R. Frank and J. Sabin in [70]. R. Frank later proved the case $\epsilon = 1$ [66].

The Jensen sum cannot be bounded by the $L^1$ norm. The next result shows that Theorem 1.13 provides the best possible result in terms of range of $\epsilon$. That is, it shows that the inequality $S_0(H_q) \leq C\|q\|_{L^1}$ cannot hold.

**Theorem 1.14** (Theorem 4.21). For all large enough $R$, we have

$$S_0(L_{\gamma,R}) \geq \frac{\gamma R}{16\pi} \log R$$  

where $L_{\gamma,R}$ denotes the operator (1.16). Consequently, we have

$$\sup_{q \in L^1(\mathbb{R}_+)} \frac{S_0(H_q)}{\|q\|_{L^1}} = \infty.$$  

The proof of this theorem is based on an application of Theorem 1.12. A similar result for Schrödinger operators on $\mathbb{R}$ has previously been obtained by S. Bögli and F. Štampach in [22].
Upper bound for critical case. While the previous result shows that $S_0(H_q)$ cannot be bounded by the $L^1$ norm, it is nonetheless possible to prove a general upper bound. Our idea is to introduce a pair of continuous, monotonically increasing weight functions $a, \hat{a} : \mathbb{R}_+ \to \mathbb{R}_+$ such that

$$a(x)\hat{a}(x) = x. \quad (1.26)$$

We then define a weighted $L^1$ norm as

$$\|q\|_a := \int_0^\infty |q(x)|a(x)dx. \quad (1.27)$$

The consideration of such weighted norms does not necessarily imply a loss of generality since, for any $q \in L^1(\mathbb{R}_+)$, it is possible to construct a weight function $a$ growing slowly enough so that $\|q\|_a < \infty$.

Most generally, our upper bound takes the following form.

**Theorem 1.15** (Theorem 4.8). Assume that the following holds.

(i) $\hat{a}$ is strictly monotonically increasing, $\hat{a}(0) = 0$ and $\hat{a}(\infty) = \infty$.

(ii) $a$ satisfies

$$\int_1^\infty \frac{dx}{xa(x)} < \infty.$$  

Then there exists $K(a,\|q\|_a) > 0$ such that for all $q \in L^1(\mathbb{R}_+)$ satisfying $\|q\|_a < \infty$, we have

$$S_0(H_q) \leq K(a,\|q\|_a). \quad (1.28)$$

In particular, (1.28) ensures that $S_0(H_q)$ is finite. An explicit expression for $K(a,\|q\|_a)$ is given in Theorem 4.8.

The purpose of Assumption (i) is to ensure that $\hat{a}$ is invertible. It imposes a restriction on how fast $a$ can grow, since $\hat{a}(\infty) = \infty$ implies that $a(x) = o(x)$ as $x \to \infty$.

Assumption (ii) necessitates that $\lim_{x \to \infty} a(x) = \infty$ and imposes a restriction on how slowly $a$ can grow. For example, if $a(x) = \log^\alpha(x - 2)$ for the some $\alpha > 0$, then the assumption is satisfied when $\alpha > 1$ but not when $\alpha \leq 1$. As a result of this assumption, Theorem 1.15 is not valid for arbitrary $L^1$ potential, although the restriction it imposes is of a logarithmic nature.

Applied to compactly supported potentials, Theorem 1.15 gives the following bound.
1.2 Critical case Lieb–Thirring inequalities

Corollary 1.16 (Corollary 4.12). Suppose the potential \( q \in L^1(\mathbb{R}_+) \) is compactly supported. Then, for every \( R > 1 \) with \( \text{supp}(q) \subset [0, R] \), we have

\[
S_0(H_q) \leq 7 \left[ \frac{1}{R} + \|q\|_1 \left( 1 + \log(1 + \|q\|_1) + \log R \right) \right].
\]

(1.29)

This bound gives the order sharp large \( R \) estimate for dissipative barrier potentials

\[
S_0(L_{\gamma,R}) = O(R \log R) \quad \text{as} \quad R \to \infty.
\]

(1.30)

Applied to potentials which decay in a polynomial sense, Theorem 1.15 gives the following bound.

Corollary 1.17 (Corollary 4.9). Let \( p \in (0, 1) \) and \( a(x) = 1 + x^p \). Then for each potential \( q \in L^1(\mathbb{R}_+) \) with \( \|q\|_a < \infty \), we have

\[
S_0(H_q) \leq \frac{4}{\pi} \|q\|_a \log(1 + \|q\|_a) + \frac{9}{p} \|q\|_a + 2.
\]

(1.31)

Upper bounds for the sum \( S_0(H_q) \) for potentials satisfying \( \|(1 + x^p)q\|_L^1 < \infty \), \( p \in (0, 1) \), have also previously been obtained by Safronov in [123]. Comparatively, our bound gives an improved asymptotic estimate for semi-classical Schrödinger operators.

An \( L^1 \) potential with divergent Jensen sum. The final result of Chapter 4 addresses the question of whether it is possible to obtain any upper bound at all for \( S_0(H_q) \) that is valid for arbitrary \( q \in L^1(\mathbb{R}_+) \). The following theorem shows that this is not possible and consequently Theorem 1.15 cannot be extended to arbitrary \( q \in L^1(\mathbb{R}_+) \).

Theorem 1.18. There exists \( q_{\infty} \in L^1(\mathbb{R}_+) \) such that \( S_0(H_{q_{\infty}}) = \infty \).

To the best of our knowledge, this result is the first which demonstrates the divergence of a Lieb–Thirring type sum for non-self-adjoint Schrödinger operators.

1.2.2 Some ideas of proofs

Our approach is based on expressing the eigenvalues as zeros of an analytic function on the upper half plane. Firstly, it is well known that there exists a unique solution \( e_+(\cdot, z) \) of \( -u'' + qu = z^2u \) on \( \mathbb{R}_+ \), known as the Jost solution, such that

\[
e_+(x, z) \sim e^{izx} \quad \text{as} \quad x \to \infty.
\]

We define the Jost function as \( e_+(z) := e_+(0, z) \). Then we have

\[
\lambda = z^2 \in \sigma_d(H_q) \quad \iff \quad e_+(z) = 0
\]
and the algebraic multiplicity of the eigenvalue coincides with the corresponding zero multiplicity. References are provided in Section 4.1 of Chapter 4.

**Non-critical upper bound.** First, we recall the following well known estimate for the Jost function,

\[ |e_+(z) - 1| \leq \exp \left( \frac{\|q\|_{L^1}}{|z|} \right) - 1, \quad z \in \mathbb{C}_+. \]  

(1.32)

Note that (1.32) not only gives an upper bound for \( |e_+(z)| \) but also a lower bound.

The next step is to move from the upper half plane \( \mathbb{C}_+ \) to the unit disk \( \mathbb{D} \). We use the following complex change of variables

\[ w = w(z) = \frac{z - i}{z + i}, \quad z = z(w) = i \frac{1 + w}{1 - w}, \quad z \in \mathbb{C}_+, \quad w \in \mathbb{D}. \]  

(1.33)

An analytic function \( f \) on the unit disk is defined as

\[ f(w) := \frac{e_+(yz(w))}{e_+(iy)}, \quad y := \frac{\|q\|_{L^1}}{\kappa}, \quad \kappa := \log \frac{3}{2}. \]  

(1.34)

The zeros of \( f \) have a bijective correspondence to the zeros of \( e_+ \). Furthermore, the estimate (1.32) for \( e_+ \), as well as the definition of \( f \), ensure that

\[ |f(0)| = 1 \quad \text{and} \quad \log |f(w)| \leq \frac{2}{|1 + w|}, \quad w \in \mathbb{D}. \]  

(1.35)

We then apply a complex analysis result of Borichev, Golinskii and Kupin to the function \( f \). In a simplified form, this result reads as follows.

**Theorem 1.19** ([24, Theorem 0.1]). Consider an analytic function \( f \) on the unit disk \( \mathbb{D} \) such that \( |f(0)| = 1 \) and

\[ \log |f(w)| \leq \frac{D}{|1 + w|} \]  

(1.36)

for some \( D > 0 \). Then for every \( \varepsilon > 0 \), there exists \( C(\varepsilon) > 0 \) such that

\[ \sum_{w \in Z(f)} (1 - |w|) |1 + w|^{\varepsilon} \leq C(\varepsilon)D \]  

(1.37)

where \( Z(f) \) denotes the set of zeros of \( f \) and zeros of higher multiplicity are repeated accordingly in the sum.

We obtain Theorem 1.13 from (1.37) by going back to the upper half plane using (1.34); the factor \((1 - |w|)\) corresponds to the factor \( \text{dist}(\lambda, \mathbb{R}_+)/|\lambda|^{1/2} \) in the summand of \( S_\varepsilon(H_q) \) and the factor \(|1 + w|^{\varepsilon}\) corresponds to the factor \(|\lambda|^{\varepsilon/2}\).
1.2 Critical case Lieb–Thirring inequalities

**Critical upper bound.** Observe that the singularity $\frac{1}{|z|}$ in (1.32) (as well as the corresponding singularity $\frac{1}{|1+w|}$ in (1.36)) is not integrable. This is the reason that the result of [24] needed to be applied instead of more elementary complex analysis results and the reason that the factor $|1+w|^\varepsilon$ in (1.37) is necessary.

A key idea in Chapter 4 is to use weight functions to obtain improved estimates for Jost functions, of the form,

$$|e_+(z) - 1| \leq \exp\left(\hat{a}\left(\frac{1}{|z|}\right)\|q\|_a\right) - 1, \quad z \in \mathbb{C}_+.$$  (1.38)

The assumption that $a$ satisfies condition (ii) of Theorem 1.15 ensures that the singularity $\hat{a}\left(\frac{1}{|z|}\right)$ is integrable.

We define an analytic function $f$ on $\mathbb{D}$ in a similar way to (1.34). Since $\hat{a}\left(\frac{1}{|z|}\right)$ is integrable, we can apply Jensen’s formula,

$$\sum_{w \in Z(f)} (1 - |w|) \leq \sum_{w \in Z(f)} \log\left(\frac{1}{|z|}\right) = \frac{1}{2\pi} \int_{-\pi}^\pi \log |f(e^{i\theta})|d\theta - \log |f(0)|.$$  (1.39)

We obtain the upper bound for $S_0(H_q)$ by estimating the right hand side of (1.39) and going back to the upper half-plane in a similar way as in the non-critical case.

**Divergent Jensen sum.** Finally, we discuss the ideas of the proof of Theorem 1.18. We utilise in an essential way some ideas of Bögli, which were used in [17] to construct complex potentials with eigenvalues accumulating to every point in the essential spectrum $[0, \infty)$.

The potential $q_\infty \in L^1(\mathbb{R}_+)$ takes the form

$$q_\infty(x) = \sum_{n=1}^\infty \gamma_n \chi_{[-R_n,R_n]}(x-X_n)$$  (1.40)

where $\gamma_n, R_n, X_n > 0$. Roughly (and non-rigorously) speaking, the idea in [17] is to make each $X_n > 0$ large enough (i.e. separating out the supports of the bumps) so that

$$\sigma_d(H_{q_\infty}) \approx \bigcup_{n=1}^\infty \sigma_d(\mathcal{L}_{\gamma_n,R_n})$$

where $\mathcal{L}_{\gamma,R} = -\frac{d^2}{dx^2} + i\gamma \chi_{[-R,R]}$ are Schrödinger operators on $L^2(\mathbb{R})$. More concretely, we are able to set each $X_n > 0$ large enough so that

$$S_0(H_{q_\infty}) \geq \frac{1}{2} \sum_{n=1}^\infty S_0(\mathcal{L}_{\gamma_n,R_n}).$$  (1.41)
Furthermore, Theorem 1.14 gives a lower bound for the rhs of (1.41). The point is then that we are able to set $\gamma_n$ and $R_n$ such that simultaneously $\|q_\infty\|_{L^1} < \infty$ and the rhs of (1.41) is infinite.

### 1.3 Rough boundaries

Given a domain $\mathcal{O} \subset \mathbb{R}^2$, (i.e. a non-empty, open, connected set) the corresponding Dirichlet Laplacian is a self-adjoint operator on $L^2(\mathcal{O})$ defined by

$$H_{\mathcal{O}}u = -\Delta u, \quad u \in D(H_{\mathcal{O}}) = \{u \in H^1_0(\mathcal{O}) : \Delta u \in L^2(\mathcal{O})\}$$

where $\Delta u$ is understood as a distribution and $H^1_0(\mathcal{O})$ is defined as the closure of $C^\infty_c(\mathcal{O})$ (i.e. smooth functions compactly supported in $\mathcal{O}$) with respect to the $H^1$ norm (which is defined by (5.5)). The Laplace operator is of fundamental importance since it encodes the dynamics of the wave equation, the free particle Schrödinger equation and the heat equation.

We are interested in the case that the domain $\mathcal{O}$ is bounded. In this case, the spectrum is purely discrete and positive,

$$\sigma(H_{\mathcal{O}}) = \sigma_d(H_{\mathcal{O}}) = \{\lambda_k(\mathcal{O})\}_{k \in \mathbb{N}} \subset \mathbb{R}_+.$$  

If $\mathcal{O}$ is sufficiently regular, if it is polygonal for instance, there exist very reliable numerical methods for computing these eigenvalues to arbitrary precision [100]. On the other hand, observe that the boundary of an arbitrary bounded planar domain may be truly pathological; it may be a fractal, it may not be locally connected and it may even have non-zero area. Intuitively, the eigenvalues for such domains, are much harder, perhaps impossible, to numerically approximate.

The underlying motivation of Chapter 5 is to understand for which classes of bounded domains the eigenvalues $\lambda_k(\mathcal{O})$, $k \in \mathbb{N}$, repeated according to geometric multiplicity, are computable. This question is addressed rigorously in the powerful framework of Solvability Complexity Indices (SCI). Roughly speaking, our results show that:

1. It is not possible to construct a numerical method able to compute the eigenvalues of an arbitrary bounded domain.

2. There exists such a numerical method for a large sub-class of bounded domains, which we explicitly specify. Domains in this class may have fractal boundaries and cusps, but must be topologically regular, i.e. $\mathcal{O} = \text{int}(\overline{\mathcal{O}})$. 
In this section, we focus on presenting the spectral theoretic results at the heart of the second statement. These provide an answer to the following question:

**Q:** Given a sequence of bounded domains \(O_n \subset \mathbb{R}^2\), \(n \in \mathbb{N}\), and a limit domain \(O \subset \mathbb{R}^2\), under what conditions does it hold that

\[
\forall k \in \mathbb{N} : \quad \lambda_k(O_n) \to \lambda_k(O) \quad \text{as} \quad n \to \infty.
\]

Rigorous statements of the computational results are postponed until Chapter 5, where SCI theory is properly introduced.

### 1.3.1 Main spectral approximation result

We now state our main spectral approximation result in a simplified form. We require a number of basic geometric notions. Recall that:

- A Jordan curve is the image of a continuous, injective map \(\iota : S^1 \to \mathbb{R}^2\), where \(S^1 \subset \mathbb{R}^2\) denotes the unit circle.

- A closed set \(K \subset \mathbb{R}^d\) is locally connected if for all \(x \in K\), there exists an open neighbourhood \(U\) of \(x\) such that \(K \cap U\) is connected.

- The Hausdorff distance between two non-empty sets \(A, B \subset \mathbb{R}^d\) is defined as

\[
\text{dist}_H(A, B) = \max \left\{ \sup_{x \in A} \text{dist}(x, B), \sup_{x \in B} \text{dist}(x, A) \right\}.
\]

We let \(\mu_{\text{leb}}(K)\) denote the Lebesgue outer measure of a set \(K \subset \mathbb{R}^2\) and, as above, \(\lambda_k(O)\) denotes the \(k\)th eigenvalue of the Dirichlet Laplacian \(H_O\).

**Theorem 1.20** (Theorem 5.3, Example 5.4 and Lemma 5.2). Let \(O \subset \mathbb{R}^2\) be a bounded, open, connected set such that \(\partial O\) is a Jordan curve with \(\mu_{\text{leb}}(\partial O) = 0\). Let \(O_n \subset \mathbb{R}^2\), \(n \in \mathbb{N}\), be a sequence of open, bounded sets such that \(\partial O_n\) is locally connected for each \(n \in \mathbb{N}\), and

\[
\text{dist}_H(O, O_n) + \text{dist}_H(\partial O, \partial O_n) \to 0 \quad \text{as} \quad n \to \infty.
\]

Then it holds that

\[
\lambda_k(O_n) \to \lambda_k(O) \quad \text{as} \quad n \to \infty.
\]

The novelty of this result lies in the generality of the class of admissible domains \(O\). Although the domains \(O\) in Theorem 1.20 are simply connected, this is not essential. A
more general version of this theorem is stated in Chapter 5, which allows for domains \( \mathcal{O} \) with holes. In fact, the only conditions on \( \mathcal{O} \) we impose there are \( \mu_{\text{leb}}(\partial \mathcal{O}) = 0 \) along with a collection of purely topological hypotheses.

Nevertheless, the hypotheses of Theorem 1.20 capture the essence of the type of domains we allow. Jordan curves are certainly not required to be locally the graph of a continuous map and admit a wide variety of fractals. However, domains with cracks, such as \( B_1(0) \setminus [0, 1] \), are not allowed, since the interior of a Jordan curve must be topologically regular \( \mathcal{O} = \text{int}(\mathcal{O}) \).

The recent papers [33, 85] obtain results which effectively cover Theorem 1.20 in the particular case that \( \mathcal{O} \) is a thick domain in the sense of Triebel or an \((\varepsilon, \infty)\)-domain. Such classes of domains also allow for domains with fractal boundaries, however our hypotheses are more topological in nature and allow for geometric features not allowed in these classes, such as cusps (see the discussion in subsection 5.2.1).

**Pixelated domains**

![Pixelated Domains](image)

Figure 1.5 An illustration of a pixelated domain approximation.

A connection between the above result and numerical analysis is provided by the following geometric approximation scheme.

**Definition 1.21.** For an open set \( \mathcal{O} \subset \mathbb{R}^2 \), the corresponding **pixelated domains** \( p_n(\mathcal{O}) \) are the open subsets of \( \mathbb{R}^2 \) defined by

\[
p_n(\mathcal{O}) := \text{int} \left( \bigcup_{j \in L_n(\mathcal{O})} \left( j + [-\frac{1}{2n}, \frac{1}{2n}]^2 \right) \right)
\]

where

\[
L_n(\mathcal{O}) := \{ j \in (n^{-1}\mathbb{Z})^2 : j \in \mathcal{O} \}.
\]

In other words, the closure of a pixelated domain is the union of boxes around the points in the grid \((n^{-1}\mathbb{Z})^2\) which lie in \( \mathcal{O} \). Note that the notation \( p_n(\mathcal{O}) \) is not used in Chapter 5. Pixelated domains are an ideal basis for a general numerical scheme since:
1.3 Rough boundaries

- $p_n(\mathcal{O})$ can be constructed solely from the knowledge of whether or not a finite number of points lie in $\mathcal{O}$, provided $\mathcal{O}$ is bounded$^8$.

- $p_n(\mathcal{O})$ may be easily triangulated.

In Proposition 5.42, we prove that, provided $\mathcal{O}$ is a bounded, topologically regular domain with $\mu_{\text{leb}}(\partial \mathcal{O}) = 0$, it holds that

$$l(n) := \text{dist}_H(\mathcal{O}, p_n(\mathcal{O})) + \text{dist}_H(\partial \mathcal{O}, \partial p_n(\mathcal{O})) \to 0 \quad \text{as} \quad n \to \infty. \quad (1.42)$$

Consequently, the eigenvalues for pixelated domains converge,

$$\forall k \in \mathbb{N} : \quad \lambda_k(p_n(\mathcal{O})) \to \lambda_k(\mathcal{O}) \quad \text{as} \quad n \to \infty.$$ 

Poincaré-type inequality

As we explain in the next subsection, the following auxiliary result plays a fundamental role in the proof of Theorem 1.20. We have not managed to find another Poincaré-type inequality of this form in the literature, although certain Hardy-type inequalities bear some resemblance (see the discussion in Subsection 5.2.2).

Intuitively, the following inequality gives a precise manner in which functions $u \in H^1_0(\mathcal{O})$ become small near the boundary $\partial \mathcal{O}$. For $r > 0$, we define a family of boundary neighbourhoods as follows

$$\partial^r \mathcal{O} := \{x \in \mathcal{O} : \text{dist}(x, \partial \mathcal{O}) < r\}.$$ 

The path components of a set are defined as the equivalence classes under the relation $x \sim y \iff x$ connected by a path to $y$.

**Theorem 1.22** (Theorem 5.6). Let $r_0 := (4\sqrt{2})^{-1}Q(\partial \mathcal{O})$, where

$$Q(\partial \mathcal{O}) := \inf \{\text{diam}(\Gamma) : \Gamma \subset \partial \mathcal{O} \text{ is a path component}\}.$$ 

Then, for any $r \in (0, r_0)$ and $u \in H^1_0(\mathcal{O})$,

$$\|u\|_{L^2(\partial^r \mathcal{O})} \leq 5r\|\nabla u\|_{L^2(\partial^r r^2 \partial \mathcal{O})}.$$ 

1.3.2 Mosco convergence and structure of the proof

The main notion that we utilise in order to prove Theorem 1.20 is that of Mosco convergence for $H^1_0$ Sobolev spaces.

$^8$More accurately, $\mathcal{O} \subset B_X(0)$, where $X > 0$ is known.
**Definition 1.23.** We have convergence $\mathcal{O}_n \overset{M}{\to} \mathcal{O}$ in the Mosco sense as $n \to \infty$ if:

(i) For all $u \in H^1_0(\mathcal{O})$, there exists $u_n \in H^1_0(\mathcal{O}_n)$, $n \in \mathbb{N}$, such that $u_n \to u$ in $H^1$ as $n \to \infty$.

(ii) For any subsequence $H^1_0(\mathcal{O}_{n_j})$, $j \in \mathbb{N}$, and any $u_j \in H^1_0(\mathcal{O}_{n_j})$, $j \in \mathbb{N}$, such that $u_j \to u$ in $H^1$ as $j \to \infty$ for some $u \in H^1(\mathbb{R}^2)$, we have $u \in H^1_0(\mathcal{O})$.

Mosco convergence can be thought of as a notion of convergence for the $H^1_0$ spaces themselves and is often denoted as $H^1_0(\mathcal{O}_n) \overset{M}{\to} H^1_0(\mathcal{O})$ as $n \to \infty$ in the literature.

If $\mathcal{O}$ is bounded, then we have the following chain of implications [118, Chapter VIII.7]

$$
\mathcal{O}_n \overset{M}{\to} \mathcal{O} \quad \Rightarrow \quad ||H^{-1}_0 - H^{-1}_\mathcal{O}||_{L^2 \to L^2} \to 0
$$

$$
\Rightarrow \quad ||P_{(a,b)}(H_{\mathcal{O}_n}) - P_{(a,b)}(H_\mathcal{O})||_{L^2 \to L^2} \to 0
$$

$$
\Rightarrow \quad \lambda_k(\mathcal{O}_n) \to \lambda_k(\mathcal{O})
$$

where all the limits are as $n \to \infty$ and $P_{(a,b)}(H)$, $a, b \in \mathbb{R}$, $a < b$, denote the spectral projections for a self-adjoint operator $H$. In other words, Mosco convergence not only implies convergence of the eigenvalues, but also of the associated eigenspaces and of the solutions of Poisson equations.

In particular, this chain of implications shows that in order to prove Theorem 1.20, it suffices to prove that $\mathcal{O}_n \overset{M}{\to} \mathcal{O}$ as $n \to \infty$ for the domains satisfying the hypotheses. Indeed, the result is formulated in terms of Mosco convergence in Chapter 5. Our first step to proving Mosco convergence is to reduce the problem to the verification of certain uniform Poincaré-type inequalities for the sequence of domains $\mathcal{O}_n$, $n \in \mathbb{N}$, as well as for the limit domain $\mathcal{O}$.

**Proposition 1.24.** Assume the hypotheses of Theorem 1.20. Suppose that there exists a sequence $\varepsilon(n) \geq 2l(n)$, $n \in \mathbb{N}$, with $\varepsilon(n) \to 0$ as $n \to \infty$ and constants $C, \alpha > 0$ independent of $n$ such that

$$
||u||_{L^2(\partial^{(\alpha)} \mathcal{O})} \leq C \varepsilon(n) ||\nabla u||_{L^2(\partial^{(\alpha)} \mathcal{O})}, \quad (1.43)
$$

$$
||v||_{L^2(\partial^{(\alpha)} \mathcal{O}_n)} \leq C \varepsilon(n) ||\nabla v||_{L^2(\partial^{(\alpha)} \mathcal{O}_n)} \quad (1.44)
$$

for all $n \in \mathbb{N}$, $u \in H^1_0(\mathcal{O})$ and $v \in H^1_0(\mathcal{O}_n)$. Then, $\mathcal{O}_n \overset{M}{\to} \mathcal{O}$ as $n \to \infty$.

The proof of this proposition involves explicitly constructing appropriate cut-off functions. For instance, to show Definition 1.23 (i), the cut-off functions $\chi_n$ are supported in $\mathcal{O}_n$, so that $u_n := \chi_n u \in H^1_0(\mathcal{O}_n)$. The Poincaré-type inequalities (1.43) and (1.44) then allow the convergence criteria to be established.
Inequality (1.43) for a single domain $\mathcal{O}$, follows directly from Theorem 1.22. Therefore, the final ingredient required for Mosco convergence is inequality (1.44) for the sequence $\mathcal{O}_n, n \in \mathbb{N}$.

Under the hypotheses of Theorem 1.20, in particular the convergence condition $l(n) \to 0$ for $\mathcal{O}_n$ to $\mathcal{O}$ (see (1.42)), we can provide a geometric characterisation of $\mathcal{O}_n$ for large $n$. More precisely, it follows from Proposition 5.38 that there exists a sequence $\varepsilon(n)$ as in Proposition 1.24 such that, for all large enough $n$, $\partial \mathcal{O}_n$ has a path-connected subset $\Gamma_n$ whose diameter exceeds $\text{diam}(\partial \mathcal{O}) - \varepsilon(n)$ and such that any other point in $\partial \mathcal{O}_n$ lies within a distance $\varepsilon(n)$ to $\Gamma_n$. As it turns out, by applying Theorem 1.22 to the domain $\mathcal{V}_n = \Gamma_n^c$, we are able to verify inequality (1.44) with $C = 10$ and $\alpha = 4 \sqrt{2}$.

1.3.3 Ideas in the proof of the Poincaré-type inequality

In this final subsection, we give an introduction to some of the main ideas in the proof of the Poincaré-type inequality Theorem 1.22.

The first thing to notice is that, since $C^\infty_c(\mathcal{O})$ is dense in $H^1_0(\mathcal{O})$, it suffices to show that there exist numerical constants $C, \alpha > 0$ and $r_0 = r_0(\mathcal{O}) > 0$ such that

$$\|u\|_{L^2(\partial r \mathcal{O})} \leq Cr\|\nabla u\|_{L^2(\partial \alpha r \mathcal{O})}, \quad r \in (0, r_0), \quad u \in C^\infty_c(\mathcal{O}).$$

Therefore, we can restrict our attention to functions $u \in C^\infty_c(\mathcal{O})$, for which the point values $u(p), p \in \mathcal{O}$, are well defined.

Fix $u \in C^\infty_c(\mathcal{O})$. Since $u$ vanishes on $\partial \mathcal{O}$, we can express the point values $u(p)$ as path integrals to the boundary. Let $\gamma_p : [0, l_p] \to \mathbb{R}^2, p \in \partial \mathcal{O}$, be an arbitrary family of piecewise smooth maps representing a bundle of paths, where, for each $p \in \partial \mathcal{O}$, $l_p > 0$ denotes the length of the path $\gamma_p$. The precise choice for $\gamma_p$ shall be further specified later. Assume that

- $\gamma_p(0) \in \partial \mathcal{O}, \gamma_p(l_p) = p$,
- $\gamma_p$ has unit speed, that is, $|\frac{d}{dt}\gamma_p(t)| = 1$ for all $t \in [0, l_p]$ and
- $\sup_{p \in \partial \mathcal{O}} l_p < \infty$.

Then we have

$$u(p) = \int_0^{l_p} \frac{d}{dt} u(\gamma_p(t)) \, dt. \quad (1.46)$$

Inserting this path integral expression into an $L^2$ norm, we get

$$\int_{\partial \mathcal{O}} |u(p)|^2 \, dp \leq \int_{\partial \mathcal{O}} \left( \int_0^{l_p} \left| \frac{d}{dt} u(\gamma_p(t)) \right| \, dt \right)^2 \, dp \leq \int_{\partial \mathcal{O}} \left( \int_0^{l_p} \left| \nabla u(\gamma_p(t)) \right| \, dt \right)^2 \, dp$$
where the fact that $\gamma_p$ is unit speed was used in the last line along with the chain rule. Furthermore, by the Cauchy-Schwarz inequality,

$$\int_0^{l_p} |\nabla u(\gamma_p(t))| \, dt \leq l_p^{1/2} \left( \int_0^{l_p} |\nabla u(\gamma_p(t))|^2 \, dt \right)^{1/2}$$

hence

$$\int_{\partial^r \mathcal{O}} |u(p)|^2 \, dp \leq \left( \sup_{p \in \partial^r \mathcal{O}} l_p \right) \int_{\partial^r \mathcal{O}} \int_0^{l_p} |\nabla u(\gamma_p(t))|^2 \, dt \, dp. \quad (1.47)$$

**Sufficient bundle of paths**

Inequality (1.47) gives rise to sufficient conditions for $\gamma_p, p \in \partial^r \mathcal{O}$, in order for the Poincaré-type inequality (1.45) to hold true. These should be verified for all $r \in (0, r_0)$.

The first condition is perhaps not surprising since every point in $\partial^r \mathcal{O}$ is a distance less than $r$ away from $\partial \mathcal{O}$.

(A) There exists a numerical constant $C_1 > 0$ such that

$$\sup_{p \in \partial^r \mathcal{O}} l_p \leq C_1 r. \quad (1.48)$$

The second condition should be verified after the first and requires that the bundle of paths does not “concentrate” too much at any given point.

(B) There exists a constant $C_2 > 0$ such that for any positive, continuous function $\phi \in L^1(\mathcal{O})$, we have

$$\int_{\partial^r \mathcal{O}} \int_0^{l_p} \phi(\gamma_p(t)) \, dt \, dp \leq C_2 r \int_{\partial^r \mathcal{O}} \phi(p) \, dp. \quad (1.49)$$

The proof of Theorem 1.22 essentially consists in explicitly constructing $\gamma_p, p \in \partial^r \mathcal{O}$, satisfying these two conditions for any domain $\mathcal{O} \subset \mathbb{R}^2$ with $Q(\partial \mathcal{O}) > 0$ and any small enough $r > 0$. Note that we do not use the notation $\gamma_p$ and $l_p$ in Chapter 5.

To help understand condition (B), and motivate the geometric constructions in Section 5.3, let us now look at some examples.

**Example 1: Half-plane**

Suppose that $\mathcal{O} = \mathbb{R}_{>0} \times \mathbb{R}$ and fix any $r > 0$. Then we can define a family of paths satisfying the above conditions by

$$\gamma_p(t) := (t, y), \quad p = (x, y). \quad (1.50)$$
1.3 Rough boundaries

Then $\gamma_p(0) = (0, y) \in \partial \mathcal{O}$, $\gamma_p$ is unit speed and, setting $l_p := x$, we have $\gamma_p(l_p) = p$.

For $p = (x, y) \in \partial \mathcal{O}$, we have $l_p = x \leq r$, so condition (A) is satisfied. Condition (B) can be seen to be satisfied by again using $x \leq r$,

$$\int_{\partial \mathcal{O}} \int_{0}^{l_p} \phi(\gamma_p(t)) \, dt \, dp = \int_{-\infty}^{\infty} \int_{0}^{r} \int_{0}^{x} \phi(t, y) \, dx \, dy \leq r \int_{-\infty}^{\infty} \int_{0}^{r} \phi(t, y) \, dt \, dy = r \int_{\partial \mathcal{O}} \phi(p) \, dp.$$ 

**Example 2: Concentrating paths**

Suppose that $\mathcal{O} = \mathbb{R}^2 \setminus \{0\}$ and fix any $r > 0$. We claim that there does not exist a family of paths $\gamma_p, p \in \partial \mathcal{O}$ satisfying the above conditions.

Assume otherwise, for contradiction. Then, $\gamma_p(0) = 0$ for all $p \in \partial \mathcal{O}$ and $\gamma_p$ has unit speed, so

$$|\gamma_p(\epsilon)| \leq \epsilon \quad \text{for all} \quad \epsilon \in (0, l_p].$$

For any $\epsilon > 0$, let $\phi_\epsilon$ be any smooth, positive function on $\mathbb{R}^2$ such that

$$\text{supp} \phi_\epsilon \subset B_\epsilon(0) \quad \text{and} \quad \phi_\epsilon \equiv 1 \quad \text{on} \quad B_{\epsilon/2}(0).$$

Then, for any $\epsilon \in (0, l_p]$,

$$\int_{\partial \mathcal{O}} \int_{0}^{l_p} \phi_\epsilon(\gamma_p(t)) \, dt \, dp \geq \int_{\partial \mathcal{O}} \int_{0}^{\epsilon/2} \phi_\epsilon(\gamma_p(t)) \, dt \, dp \geq \frac{\pi r^2 \epsilon}{2}$$
and, for any $\alpha > 0$,
\[
\int_{\partial r} \phi_\varepsilon (p) dp \leqslant \pi \varepsilon^2,
\]
from which it can be readily seen that condition (B) cannot hold for any fixed $r > 0$.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure1.jpg}
\caption{(left) An illustration of an incompatible family of paths for the domain in Example 3. (right) An illustration of the compatible family of paths described in Example 3.}
\end{figure}

**Example 3: Turning the corner**

Consider the domain $\mathcal{O} = \mathbb{R}^2 \setminus (\mathbb{R}_{\leq 0} \times \mathbb{R}_{\leq 0})$ and fix any $r > 0$. Then $\mathcal{O}$ has a reentrant corner at the point $(0,0)$. Focus on the problem of constructing a family paths $\gamma_p$ from $\partial \mathcal{O}$ to points in the region $U = (\mathbb{R}_{> 0} \times \mathbb{R}_{> 0}) \cap \partial^r \mathcal{O}$.

Suppose that we construct $\gamma_p$ as illustrated in the left part of Figure 1.7, so that $\gamma_p(0) = (0,0)$ for all $p \in U$. Then the paths $\gamma_p$, $p \in U$, concentrate in a similar way to the previous example and condition (B) cannot hold by similar reasoning.

Nevertheless, it is possible to construct a family of paths $\gamma_p$, $p \in \partial^r \mathcal{O}$, satisfying both conditions (A) and (B) above. For $p = (x,y) \in U$, we let
\[
\gamma_p(t) := \begin{cases} 
(-y,t) & \text{if } t \in [0,y] \\
(-2y + t,y) & \text{if } t \in (y,2y+x). 
\end{cases}
\]  
(1.51)

On the other hand, for $p \in \partial^r \mathcal{O}$, for $p \in \partial^r \mathcal{O} \setminus U$, define $\gamma_p$ analogously to (1.50), as illustrated in the right part of Figure 1.7.
1.3 Rough boundaries

Clearly, \( l_p = 2y + x \leq 3r \) for \( p \in U \), and \( l_p = r \) otherwise, so condition (A) is satisfied. Since \( x, y \leq r \) for \( p = (x, y) \in U \), we have

\[
\int_U \int_0^{l_p} \phi(\gamma_p(t)) \, dt \, dp \leq \int_0^r \int_0^y \left( \int_0^y \phi(-y, t) \, dt + \int_y^3 \phi(-2y + t, y) \, dt \right) \, dx \, dy
\]

\[
= r \int_0^r \int_{-r}^r \phi(x, y) \, dx \, dy \leq r \int_{\partial \sqrt{2} \partial \mathcal{O}} \phi(p) \, dp.
\]

The reasoning of Example 1 shows that the analogous inequality for \( \partial^r \mathcal{O} \backslash U \) also holds so condition (B) is satisfied.

![Cell-paths, g-cells and lg-cells](image)

Figure 1.8 (top) An illustration of a g-cell and an lg-cell. (left) An illustration of a construction of a bundle of paths from a nearby g-cell. (right) An illustration of a construction of a bundle of paths from a nearby lg-cell.

Cell-paths, g-cells and lg-cells

In Section 5.3, we construct a similar bundle of paths for an arbitrary open set \( \mathcal{O} \subset \mathbb{R}^2 \) with \( Q(\partial \mathcal{O}) > 0 \) and \( r \in (0, r_0) \) where \( r_0 = (4\sqrt{2})^{-1}Q(\partial \mathcal{O}) \). Roughly speaking, the construction can be summarised as follows.

1. Decompose \( \mathbb{R}^2 \) into a union of closed boxed (which we call cells), of size \( r > 0 \).

2. Consider an arbitrary cell \( c_0 \) such that \( c_0 \cap \partial^r \mathcal{O} \neq \emptyset \).

3. A g-cell (or an lg-cell) is a cell (or a pair of cells resp.) such that the boundary bisects the cell(s) as shown in the top part of Figure 1.8. Find a g-cell or an lg-cell near to \( c_0 \) (see Lemma 5.27).
4. Find an appropriate path of adjacent cells (a cell-path) from \( c_0 \) to the g-cell or lg-cell (see Lemma 5.28).

5. Construct a bundle paths \( \gamma_p, p \in c_0 \cap \partial r \) from \( \partial r \) to each point in \( c_0 \) within the cell path (see Proposition 5.26).
Chapter 2

The Dissipative Barrier Method

Declaration:
This chapter appears in a similar form in the published article [130].

2.1 Introduction

In this chapter, we study the eigenvalues of linear operators under a certain class of perturbations with an emphasis on Schrödinger operators of the form,

$$T_R = -\frac{d^2}{dx^2} + q + i\gamma \chi_{[0,R]}$$

on \(L^2(0,\infty)\), (2.1)

equipped with a complex mixed boundary condition at 0, where \(\chi\) is the characteristic function and \(q\) is a possibly complex-valued multiplication operator. Specifically, we are concerned with how the eigenvalues of \(T_R\) approximate the spectrum of the limit operator \(T = -\frac{d^2}{dx^2} + q + i\gamma\). As well as giving a precise account for the case of Schrödinger operators \(T_R\) with the background potential \(q\) either in \(L^1\) or eventually real periodic, we give general results for abstract operators of this form, utilising the notion of limiting essential spectrum recently introduced by Bögli (2018) [18].

It is well known that the numerical approximation of the spectra of linear operators is often complicated by the possible presence of spectral pollution [16, 51, 91, 116]. The primary motivation for this chapter is the justification of the dissipative barrier method, designed to circumvent such issues.

The perturbations we consider belong to a class of operators which are often referred to as complex absorbing potentials in the context of Schrödinger operators. These arise in the study of the damped wave equation [38, 39, 72], in the computation of resonances in quantum chemistry [119, 128, 139] and in the study of resonances in quantum chaos [109, 110].
2.1.1 Spectral inclusion and pollution

Let us now introduce the abstract notions of spectral inclusion and pollution. Suppose that we are interested in approximating the spectrum of a (linear) operator $H$ on a Hilbert space $\mathcal{H}$ with domain $D(H)$. Let $(H_n)$ be a sequence of operators on $\mathcal{H}$ whose spectra $\sigma(H_n)$ we hope will approximate the spectrum $\sigma(H)$ of $H$ as $n \to \infty$. The limiting spectrum of $(H_n)$ is defined by

$$\sigma((H_n)) = \{ \lambda \in \mathbb{C} : \exists I \subseteq \mathbb{N} \text{ infinite, } \exists \lambda_n \in \sigma(H_n), n \in I \text{ with } \lambda_n \to \lambda \}. \quad (2.2)$$

$(H_n)$ is said to be spectrally inclusive for $H$ in some $\Omega \subseteq \mathbb{C}$ if

$$\sigma(H) \cap \Omega \subseteq \sigma((H_n)). \quad (2.3)$$

The set of spectral pollution for $(H_n)$ with respect to $H$ is defined by

$$\sigma_{\text{poll}}((H_n)) = \{ \lambda \in \sigma((H_n)) : \lambda \notin \sigma(H) \}. \quad (2.4)$$

In order to reliably approximate the spectrum of $H$ in $\Omega \subseteq \mathbb{C}$ using $(H_n)$, we require that there is no spectral pollution in $\Omega$, $\sigma_{\text{poll}}((H_n)) \cap \Omega = \emptyset$, and that $(H_n)$ is spectrally inclusive for $H$ in $\Omega$. If this holds, we say that $(H_n)$ is spectrally exact for $H$ in $\Omega$.

A typical scenario in which the set of spectral pollution may be non-empty is one in which $H$ and $H_n$ are self-adjoint, the essential spectrum $\sigma_e(H)$ of $H$ has a band-gap structure and the operators $H_n$ have compact resolvents (i.e. $H_n$ have purely discrete spectra). For this reason, spectral pollution often causes issues for the numerical computation of eigenvalues in spectral gaps. Various methods have been proposed to deal with such issues, we mention for instance [26, 51, 82, 97, 98, 138]. We focus on one such method, which involves perturbing the operator of interest such as to move the spectrum, in a predictable way, away from the set of spectral pollution caused by numerical discretisation [104].

2.1.2 Dissipative Barrier Method

Let us now describe this method. Let $T_0$ be a self-adjoint operator on a Hilbert space $\mathcal{H}$; suppose we are interested in numerically computing the spectrum of $T_0$. A dissipative barrier method consist in perturbing $T_0$ by $i\gamma s_n$, where $(s_n)$ is a bounded sequence of self-adjoint, $T_0$-compact operators on $\mathcal{H}$ tending strongly to the identity operator. If $\mathcal{H} = L^2(0, \infty)$, for instance, a typical choice for $s_n$ would be $\chi_{[0,n]}$. Define
the perturbed operators by

\[ T_n = T_0 + i\gamma s_n \quad (n \in \mathbb{N}), \]  

(2.5)

where \( \gamma > 0 \). The limit operator \( T \) is defined by \( T = T_0 + i\gamma \). The spectrum of \( T_0 \) is exactly encoded in the spectrum of \( T \) since \( \sigma(T) = \sigma(T_0) + i\gamma \).

Under appropriate additional conditions on \( T_0 \) and \( s_n \), it can be proved that there exist spectrally inclusive numerical methods for the computation of \( \sigma(T_n) \) for fixed \( n \) [4, 102–104, 133]. Furthermore, any spectral pollution for these numerical methods lies on \( \mathbb{R} \), away from \( \sigma(T) \) uniformly in \( n \). The recently introduced notion of essential numerical range for unbounded operators can be used to prove general results of this form (see Theorems 4.5, 6.1 and 7.1 in [21]). Thanks to such numerical methods for \( \sigma(T_n) \), if \( (T_n) \) can be shown to be spectrally exact for \( T \) in an open neighbourhood in \( \mathbb{C} \) of a closed subset \( i\gamma + I \subseteq i\gamma + \mathbb{R} \), then in principle one can reliably numerically compute the spectrum of \( T_0 \) in \( I \).

### 2.1.3 Analysis of expanding barriers

The aim of this chapter is to provide spectral inclusion and spectral pollution results for sequences of operators of the form (2.5).

In Section 2.2, we work in an abstract setting, utilising the limiting essential spectrum \( \sigma_e((T_n)) \) [18], which is a set enclosing the regions in \( \mathbb{C} \) where spectral exactness for \( (T_n) \) with respect to \( T \) may fail. With additional assumptions on the operators \( s_n \), for instance that they are projection operators, we prove new types of non-convex enclosures for \( \sigma_e((T_n)) \) and conclude for these cases that \( (T_n) \) is spectrally exact for \( T \) in an open neighbourhood of any eigenvalue of \( T \). The chapter [84] gives a similar spectral exactness conclusion for the case that \( (s_n) \) are projection operators. However, as well as including different classes of perturbations \( (s_n) \), both the statement and the proof of our results in Section 2.2 are far simpler than those of [84], owing to the use of the limiting essential spectrum.

The remainder of the chapter is devoted to a more precise analysis for the case of Sturm-Liouville operators on the half-line. Our results in Sections 2.3 and 2.4 apply to operators for which the solutions of the corresponding Sturm-Liouville equation satisfy a certain decomposition. In particular, this decomposition is easily shown to be satisfied by Schrödinger operators \( T_R \) of the form (2.1) with the background potential \( q \) either in \( L^1 \) or real eventually periodic. In Section 2.3, we show that any eigenvalue of the limit operator \( T \equiv T_0 + i\gamma \equiv -d^2/dx^2 + q + i\gamma \) for these cases is approximated by the spectrum of \( T_R \) with exponentially small error as \( R \to \infty \). A similar result was
proved in [104, Theorem 10], but only for $\gamma$ sufficiently small. In Section 2.4 we show that the essential spectrum of $T$ is approximated by the eigenvalues of $T_R$ with an error of order $O(1/R)^1$. The latter result is the first of its type to be reported.

We also characterise the set of spectral pollution for the two cases of perturbed Schrödinger operators $T_R$. Let $(R_n) \subset \mathbb{R}_+$ be any sequence such that $R_n \to \infty$. Since the dissipative barrier perturbations $i\gamma \chi_{[0,R_n]}$ are relatively compact, the essential spectrum $\sigma_e(T_0)$ is contained in the spectral pollution $\sigma_{\text{poll}}((T_{R_n}))$ by Weyl’s Theorem\(^2\). Note that this is in contrast to typical examples of spectral pollution, due to numerical discretisation, which are caused by spurious eigenvalues. It is shown in Section 2.3 that $\sigma_e(T_0)$ is the only possible source of spectral pollution for the case $q \in L^1$. We encourage the reader to inspect Figures 2.2 and 2.3 in Section 2.5, which illustrate the eigenvalues of $T_R$ for this case. For $q$ eventually real periodic, the set of spectral pollution outside $\sigma_e(T_0)$ is enclosed in the set of zeros of a certain analytic function constructed from solutions of (time-independent) Schrödinger equations. In fact, we prove that these zeros are contained inside the limiting essential spectrum $\sigma_e((T_{R_n}))$.

Figure 2.4 in Section 2.5 shows how spectral pollution may occur in this second case.

### 2.1.4 Summary of results

#### Limiting essential spectrum and spectral pollution

In Section 2.2, we consider a self-adjoint operator $T_0$ on Hilbert space $\mathcal{H}$. It is assumed that the operators $s_n \ (n \in \mathbb{N})$ on $\mathcal{H}$ are self-adjoint, tend strongly to the identity operator as $n \to \infty$ and are bounded independently of $n$. For $\gamma > 0$, we define the perturbed operators $T_n \ (n \in \mathbb{N})$ by (2.5) and the limit operator by $T = T_0 + i\gamma$.

The main tool in this section is the notion of *limiting essential spectrum* $\sigma_e((T_n))$ (see Definition 2.1). The results of [18] show that (Corollary 2.7)

$$(T_n) \text{ is spectrally exact for } T \text{ in } \mathbb{C} \setminus [\sigma_e((T_n)) \cup \sigma_e((T_n)^*) \cup \sigma_e(T)].$$

The *limiting essential numerical range* $W_e((T_n))$ of $(T_n)$ (see Definition 2.5), introduced by Bögli, Marletta and Tretter (2020), is a convex set which in our set-up satisfies (Propositions 2.6 and 2.9)

$$\sigma_e((T_n)) \cup \sigma_e((T_n)^*) \subset W_e((T_n)) \subset \text{conv}(\sigma_e(T_0)) \setminus \{\pm \infty\} + i\gamma[s_-, s_+].$$

\(^1\)Although band-ends and embedded resonances may have a different rate of convergence.

\(^2\)With the possible exception of a few isolated points if $T_0$ is non-self-adjoint.
where $\hat{\sigma}_e(T_0)$ denotes the extended essential spectrum of $T_0$ (see Definition 2.8) and $s_{\pm} \in \mathbb{R}$ (defined by (2.11)) satisfy $s_- - \varepsilon \leq s_n \leq s_+ + \varepsilon$ for any $\varepsilon > 0$ and large enough $n$.

The main results of Section 2.2 are non-convex enclosures for $\sigma_e((T_n))$ complementing the enclosure provided by $W_e((T_n))$.

(A) (Theorem 2.12) If $s_n$ is a projection operator for all $n$, that is $s_{\pm}$, then $\sigma_e((T_n)) \cup \sigma_e((T_n^*))^* \subset \Gamma_a = \Gamma_a(\sigma_e(T_0), \gamma)$, where

$$\Gamma_a := \left\{ \lambda \in \mathbb{C} : \text{Im}(\lambda) \in [0, \gamma], \text{dist(Re}(\lambda), \sigma_e(T_0)) \leq \sqrt{\text{Im}(\lambda)(\gamma - \text{Im}(\lambda))} \right\}.$$ 

Alternatively, if for any sequence $(u_n) \subset D(T_0)$ bounded in $H$ with $(T_0 u_n)$ bounded in $H^\prime$ we have

$$\langle s_n u_n, T_0 u_n \rangle - \langle T_0 u_n, s_n u_n \rangle \to 0 \quad \text{as} \quad n \to \infty$$

(Assumption 2.11) then $\sigma_e((T_n)) \cup \sigma_e((T_n^*))^* \subset \Gamma_b = \Gamma_b(\sigma_e(T_0), \gamma, s_{\pm})$, where

$$\Gamma_b := \sigma_e(T_0) + i\gamma |s_-, s_+|.$$ 

In particular, if $s_n$ are projection operators or if Assumption 2.11 is satisfied then

$$(T_n)$$ is spectrally exact for $T$ in some open neighbourhood of any $\lambda \in \sigma_d(T)$.

We clarify that by open neighbourhood we mean open neighbourhood in $\mathbb{C}$. The enclosures $\Gamma_a$ and $\Gamma_b$ are illustrated in Figure 2.1. Assumption 2.11 is verified for a class of perturbations for Schrödinger operators on Euclidean domains in Example 2.14.

Second order operators on the half-line

In Section 2.3, we consider the case in which $T_0$ is a Sturm-Liouville operator on $L^2(0, \infty)$ and provide a more precise analysis compared to Section 2.2. The Sturm-Liouville operator $T_0$ is allowed to have complex coefficients and is endowed with a complex mixed boundary condition at 0.

We assume that for any $\lambda \in \mathbb{C} \setminus \sigma_e(T_0)$, the solution space of the equation $\hat{T}_0 u = \lambda u$ (here, $\hat{T}_0$ is the differential expression corresponding to $T_0$) is spanned by solutions $\psi_{\pm}(\cdot, \lambda)$ admitting the decomposition

$$\psi_{\pm}(x, \lambda) = e^{\pm ik(\lambda)x} \tilde{\psi}_{\pm}(x, \lambda).$$
Here, $k$ and $\tilde{\psi}_\pm(x, \cdot)$ are analytic functions on $\mathbb{C} \setminus \sigma_e(T_0)$ with $\text{Im} k > 0$ and with $\tilde{\psi}_\pm(\cdot, \lambda)$ bounded. A similar decomposition is required for $\psi'_\pm$ - see Assumption 2.15 for the precise statement.

The perturbed operators in Section 2.3 are defined by

$$T_R = T_0 + i\gamma \chi_{[0,R]} \quad (R \in \mathbb{R}_+)$$

where $\gamma \in \mathbb{C} \setminus \{0\}$. The limit operator is defined by $T = T_0 + i\gamma$. Under these assumptions, for any $(R_n)$ with $R_n \to \infty$, we construct a set $S_p((R_n))$ (equation (2.42)) and prove the following:

(B) (Theorems 2.23 and 2.24) For any eigenvalue $\lambda$ of $T$ with $\lambda \notin S_p((R_n))$ and $\lambda \notin \sigma_e(T_0)$, there exists eigenvalues $\hat{\lambda}_n$ of $T_{R_n}$ ($n$ large enough) such that

$$|\lambda - \hat{\lambda}_n| = O(e^{-\beta R_n}) \text{ as } n \to \infty$$

for some $\beta > 0$ independent of $n$. Furthermore, the set of spectral pollution for $(T_{R_n})$ with respect to $T$ satisfies

$$\sigma_{\text{poll}}((T_{R_n})) \subseteq \sigma_e(T_0) \cup S_p((R_n)).$$

The proofs utilise Rouché’s theorem applied to an analytic function (Lemma 2.19) whose zeros are the eigenvalues of $T_R$. (B) implies that

$(T_{R_n})$ is spectrally exact for $T$ in $\mathbb{C} \setminus (\sigma_e(T_0) \cup \sigma_e(T) \cup S_p((R_n)))$.

Assumption 2.15 is verified in two cases:

- (Examples 2.17 and 2.25) $T_0$ is a Schrödinger operator with an $L^1$ potential. In this case, $S_p((R_n)) = \emptyset$.

- (Examples 2.18 and 2.26) $T_0$ is a Schrödinger operator with an eventually real $a$-periodic potential, $\gamma > 0$ and $R_n - R_{n-1} = a$ for all $n$. In this case, $S_p((R_n))$ is expressed as the zeros of a certain analytic function (equation (2.51)). It is also proved that $S_p((R_n)) \subset \sigma_e((T_n))$.

Inclusion for the essential spectrum

In Section 2.4, we let $T_0$ be a Sturm-Liouville operator satisfying Assumption 2.15, as described above. In addition, we require that $\sigma_e(T_0) \subseteq \mathbb{R}$ and that $k$ and $\tilde{\psi}_+(x, \cdot)$,
hence $\psi_+(x, \cdot)$, admit analytic continuations into an open neighbourhood of any point in the interior of $\sigma_e(T_0)$. See Assumption 2.27 for the precise statement.

The perturbed operators $T_R$ and the limit operator in Section 2.4 are defined by (2.6) and $T = T_0 + i\gamma$ respectively, as in Section 2.3. We construct a set $S_e \subseteq i\gamma + \mathbb{R}$ (equation (2.65)) and prove that:

(C) (Theorem 2.33) For any $\mu$ in the interior of $\sigma_e(T_0)$ with $\mu + i\gamma \notin S_e$, there exists eigenvalues $\lambda_R$ of $T_R$ ($R$ large enough) such that

$$|\lambda_R - (\mu + i\gamma)| = O\left(\frac{1}{R}\right) \text{ as } R \to \infty.$$ 

The proof utilises Rouché’s theorem applied to an analytic function (Lemma 2.30) whose zeros are the eigenvalues of $T_R$. In the case that

- (Examples 2.28 and 2.38) $T_0$ is a Schrödinger operator with an $L^1$ potential satisfying the Naimark condition or a dilation analyticity condition, or,

- (Examples 2.29 and 2.39) $\gamma > 0$ and $T_0$ is a Schrödinger operator with a real, eventually periodic potential, endowed with a real mixed boundary condition at 0,

it is proven that Assumption 2.27 is satisfied and that

$$\mu + i\gamma \in S_e \text{ if and only if } \mu \text{ is a resonance of } T_0 \text{ embedded in } \sigma_e(T_0).$$

See equation (2.79) for the precise definition of a resonance used here. For these cases, since resonances in the interior of $\sigma_e(T_0)$ are isolated, we can combine Theorem 2.33 with Theorem 2.24 and the characterisation of $S_p((R_n))$ to conclude that

$(T_n)$ is spectrally exact for $T$ in some open neighbourhood of any $\mu \in \text{int}(\sigma_e(T))$.

**Notation and conventions**

Recall the notations and conventions given at the beginning of Chapter 1. In addition, in Sections 2.3 and 2.4, $\psi'(x, z) := \frac{d}{dx}\psi(x, z)$. Also, for sets $\Omega \subset \mathbb{C}$, we define

$$\Omega^* = \{ \bar{z} : z \in \Omega \}.$$
2.2 Limiting essential spectrum and spectral pollution

In this section, we study spectral exactness for sequences of abstract operators \((T_n)\) of the form (2.5). In Section 2.2.1, we briefly review the notions of limiting essential spectrum and essential numerical range. We refer the reader to [18] and [21] for a more detailed exposition. In Section 2.2.2, we discuss the application of limiting essential spectrum and essential numerical range to \((T_n)\). In Section 4.4.4, we prove enclosures for the limiting essential spectrum of \((T_n)\).

2.2.1 Limiting essential spectrum and numerical range

Throughout this subsection, let \(H\) and \(H_n (n \in \mathbb{N})\) be closed, densely-defined operators acting on \(\mathcal{H}\).

**Definition 2.1.** The limiting essential spectrum of \((H_n)\) is defined by

\[
\sigma_e((H_n)) = \left\{ \lambda \in \mathbb{C} : \exists I \subseteq \mathbb{N} \text{ infinite}, \exists u_n \in D(H_n), n \in I \text{ with } \|u_n\| = 1, \ u_n \rightharpoonup 0, \ \|(H_n - \lambda)u_n\| \to 0 \right\}.
\]  

(2.7)

Note that the terminology “limiting essential spectrum” is a slight misnomer since in general we cannot be certain that the limiting essential spectrum is a subset of the limiting spectrum (see Theorem 2.3, noting that the set of spectral pollution \(\sigma_{\text{poll}}((H_n))\) is a subset of the limiting spectrum \(\sigma((H_n))\)).

**Definition 2.2.** \((H_n)\) converges to \(H\) in the strong resolvent sense, denoted by \(H_n \overset{\text{sr}}{\to} H\), if

\[
\exists n_0 \in \mathbb{N} : \exists \lambda_0 \in \bigcap_{n \geq n_0} \rho(H_n) \cap \rho(H) : (H_n - \lambda_0)^{-1} \overset{\text{s}}{\to} (H - \lambda_0)^{-1}.
\]

**Theorem 2.3** ([18, Theorem 2.3]). If \(H_n \overset{\text{sr}}{\to} H\) and \(H_n^* \overset{\text{sr}}{\to} H^*\) then

\[
\sigma_{\text{poll}}((H_n)) \subset \sigma_e((H_n)) \cup \sigma_e((H_n^*))^*
\]  

(2.8)

and every isolated \(\lambda \in \sigma(H)\) outside \(\sigma_e((H_n)) \cup \sigma_e((H_n^*))^*\) is approximated by \((H_n)\), that is,

\[
\{ \lambda \in \sigma(H) : \lambda \text{ isolated, } \lambda \notin \sigma_e((H_n)) \cup \sigma_e((H_n^*))^* \} \subset \sigma((H_n)).
\]

**Definition 2.4.** The essential numerical range of \(H\) is defined by

\[
W_e(H) = \{ \lambda \in \mathbb{C} : \exists (u_n) \subset D(H) \text{ with } \|u_n\| = 1, \ u_n \rightharpoonup 0, \ \langle Hu_n, u_n \rangle \to \lambda \}.
\]
Definition 2.5. The limiting essential numerical range of $(H_n)$ is defined by

$$W_e((H_n)) = \left\{ \lambda \in \mathbb{C} : \exists I \subseteq \mathbb{N} \text{ infinite, } \exists u_n \in D(H_n), n \in I \text{ with} \right. \left. \|u_n\| = 1, u_n \to 0, \langle H_nu_n, u_n \rangle \to \lambda \right\}.$$

(2.9)

Proposition 2.6 ([21, Proposition 5.6]). The limiting essential numerical range of $(H_n)$ is closed and convex with

$$\text{conv}(\sigma_e((H_n))) \subset W_e((H_n)).$$

Furthermore, if $D(H_n) \cap D(H_n^*)$ is a core of $H_n^*$ for all $n$ then

$$\text{conv}(\sigma_e((H_n)) \cup \sigma_e((H_n^*))^*) \subset W_e((H_n)).$$

2.2.2 Enclosures for the limiting essential spectrum

Throughout the remainder of the section, let $T_0$ and $s_n (n \in \mathbb{N})$ be self-adjoint operators on $\mathcal{H}$. Let $\gamma > 0$ and define the perturbed operators, as in the introduction, by

$$T_n = T_0 + i\gamma s_n. \quad (n \in \mathbb{N})$$

(2.10)

Assume that $s_n \xrightarrow{s} I$ and that $\|s_n\| \leq C$ for some $C > 0$ independent of $n$. Define the limit operator by $T = T_0 + i\gamma$ as in the introduction - $T_n$ converges strongly to $T$.

Corollary 2.7. $(T_n)$ is spectrally exact for $T$ in $\mathbb{C}\backslash[\sigma_e((T_n)) \cup \sigma_e((T_n^*))^* \cup \sigma_e(T)]$

Proof. The fact that $T_n \xrightarrow{s} T$ and $T_n^* = T_0 - i\gamma s_n \xrightarrow{s} T_0 - i\gamma = T^*$ follows from an application of the resolvent identity, using $s_n \xrightarrow{s} I$, the self-adjointness of $T_0$ and the uniform boundedness of the sequence of operators $(s_n)$. By Theorem 2.3, $\sigma_{\text{poll}}((T_n)) \subset \sigma_e((T_n)) \cup \sigma_e((T_n^*))^*$ and

$$\{\lambda \in \sigma(T) : \lambda \text{ isolated, } \lambda \notin \sigma_e((T_n)) \cup \sigma_e((T_n^*))^* \} \subset \sigma((T_n)).$$

The corollary follows from the fact that every element of $\sigma_d(T) = \sigma_d(T_0) + i\gamma$ is isolated since $T_0$ is self-adjoint [61].

Since $D(T_n) = D(T_n^*) = D(T_0)$, Proposition 2.6 implies that the set $\sigma_e((T_n)) \cup \sigma_e((T_n^*))^*$ is contained in the limiting essential numerical range $W_e((T_n))$ and so $(T_n)$ is spectrally exact for $T$ in $\mathbb{C}\backslash[W_e((T_n)) \cup \sigma_e(T)]$. The limiting essential numerical range is typically easier to study than the limiting essential spectrum. For sequences of operators of the form (2.10), the limiting essential numerical range $W_e((T_n))$ is
The Dissipative Barrier Method

42

Definition 2.8. The extended essential spectrum \( \hat{\sigma}_e(H) \subset \sigma_e(H) \cup \{ \pm \infty \} \) of a self-adjoint operator \( H \) on \( \mathcal{H} \) is defined as the union of \( \sigma_e(H) \) with \( +\infty \) and/or \( -\infty \) if \( H \) is unbounded from above and/or below respectively.

Throughout the remainder of the section, let

\[
\begin{align*}
    s_- &= \liminf_{n \to \infty} \inf_{u \in \mathcal{H} : \|u\| = 1} \langle s_n u, u \rangle \\
    s_+ &= \limsup_{n \to \infty} \sup_{u \in \mathcal{H} : \|u\| = 1} \langle s_n u, u \rangle.
\end{align*}
\]

(2.11)

Then, for any \( \varepsilon > 0 \) and sufficiently large \( n \), \( s_- - \varepsilon \leq s_n \leq s_+ + \varepsilon \).

Proposition 2.9. \( W_e((T_n)) \subset \left[ \text{conv}(\hat{\sigma}_e(T_0)) \setminus \{ \pm \infty \} \right] + i\gamma(s_-, s_+) \)

Proof. Let \( \lambda \in W_e((T_n)) \). Then there exist \( I \subset \mathbb{N} \) infinite and \( (u_n)_{n \in I} \subset D(T_0) \) such that \( \|u_n\| = 1 \) for all \( n \in I \), \( u_n \rightarrow 0 \) and \( \langle (T_n - \lambda)u_n, u_n \rangle \rightarrow 0 \). Taking the real part of the inner product, we have \( \langle (T_0 - \text{Re}(\lambda))u_n, u_n \rangle \rightarrow 0 \) which implies that

\[
\text{Re}(\lambda) \in W_e(T_0) = \text{conv}(\hat{\sigma}_e(T_0)) \setminus \{ \pm \infty \}
\]

where we used [21, Theorem 3.8] in the equality. Finally, \( \text{Im}(\langle (T_n - \lambda)u_n, u_n \rangle) \rightarrow 0 \) implies that \( \text{Im}(\lambda) = \gamma(s_n u_n, u_n) + o(1) \in \gamma(s_-, s_+) \).

2.2.3 Main abstract results

In the main result of this section, Theorem 2.12, we shall prove non-convex enclosures for the limiting essential spectrum \( \sigma_e((T_n)) \) that complement the enclosure provided by the limiting essential numerical range. We shall require additional assumptions on the perturbing operators \( (s_n) \). In part (a) of the theorem, we simply require that \( s_n \) are projection operators. An interesting feature of the enclosure of part (a) is that it is independent of the perturbing operators \( (s_n) \), depending only on \( \sigma_e(T_0) \) and \( \gamma \). The hypothesis for part (b) of the theorem, Assumption 2.11, is given below. An example of a class of perturbations for Schrödinger operators satisfying this assumption is provided in Example 2.14. The enclosures are illustrated in Figure 2.1.

Lemma 2.10. Let \( H \) be a self-adjoint operator on \( \mathcal{H} \). If for some \( \eta \in \mathbb{R} \) and \( \varepsilon > 0 \) there exists a sequence \( (u_n) \subset D(H) \) with \( \|u_n\| = 1 \) for all \( n \), \( u_n \rightarrow 0 \) and \( \|(H - \eta)u_n\| \rightarrow \varepsilon \) then

\[
\text{dist}(\eta, \sigma_e(H)) \leq \varepsilon.
\]
2.2 Limiting essential spectrum and spectral pollution

Assumption 2.11. If \( T \) is a projection operator, that is \( s_n^2 = s_n \), for all \( n \), then \( \sigma_e((T_n)) \cup \sigma_e((T_n^*))^* \subset \Gamma_a = \Gamma_a(\sigma_e(T_0), \gamma) \) where

\[
\Gamma_a := \left\{ \lambda \in \mathbb{C} : \text{Im}(\lambda) \in [0, \gamma], \text{dist}(\text{Re}(\lambda), \sigma(\Gamma_0)) \leq \sqrt{\text{dist}}(\lambda, (\gamma - \text{Im}(\lambda))) \right\}.
\]

(2.12)

(b) If Assumption 2.11 holds then \( \sigma_e((T_n)) \cup \sigma_e((T_n^*))^* \subset \Gamma_b = \Gamma_b(\sigma_e(T_0), \gamma, s_{\pm}) \) where

\[
\Gamma_b := \sigma_e(T_0) + i\gamma[s_{-}, s_{+}].
\]

(2.13)

Proof. For any \( \delta > 0 \) there exists \( N_\delta \in \mathbb{N} \) such that \( \| (H - \eta)u_n \| < (\varepsilon + \delta)\|u_n\| \) for all \( n \geq N_\delta \). \( (u_n)_{n \geq N_\delta} \) is a non-compact, bounded sequence so by [76, Chapter I, Theorem 10] the interval \( (\eta - (\varepsilon + \delta), \eta + (\varepsilon + \delta)) \) contains an infinite number of points in \( \sigma(H) \). Taking the limit \( \delta \to 0 \) shows that the interval \( [\eta - \varepsilon, \eta + \varepsilon] \) contains an infinite number of points in \( \sigma(H) \). Finally, \( [\eta - \varepsilon, \eta + \varepsilon] \) must contain a point of \( \sigma_e(H) \) because any limit point of \( \sigma_\delta(H) \) is in \( \sigma_e(H) \). \( \square \)

Assumption 2.11. If \( (u_n) \subset D(T_0) \) is bounded in \( \mathcal{H} \) with \( (T_0u_n) \) bounded in \( \mathcal{H} \) then

\[
\langle s_nu_n, T_0u_n \rangle - \langle T_0u_n, s_nu_n \rangle \to 0 \quad \text{as} \quad n \to \infty.
\]

Theorem 2.12. (a) If \( s_n \) is a projection operator, that is \( s_n^2 = s_n \), for all \( n \), then

\[
\sigma_e((T_n)) \cup \sigma_e((T_n^*))^* \subset \Gamma_a = \Gamma_a(\sigma_e(T_0), \gamma)
\]

where

\[
\Gamma_a := \left\{ \lambda \in \mathbb{C} : \text{Im}(\lambda) \in [0, \gamma], \text{dist}(\text{Re}(\lambda), \sigma_e(T_0)) \leq \sqrt{\text{dist}}(\lambda, (\gamma - \text{Im}(\lambda))) \right\}.
\]

(2.12)

(b) If Assumption 2.11 holds then \( \sigma_e((T_n)) \cup \sigma_e((T_n^*))^* \subset \Gamma_b = \Gamma_b(\sigma_e(T_0), \gamma, s_{\pm}) \) where

\[
\Gamma_b := \sigma_e(T_0) + i\gamma[s_{-}, s_{+}].
\]

(2.13)

Proof. We will only prove that \( \sigma_e((T_n)) \subset \Gamma_a \) or \( \Gamma_b \) - the proof that \( \sigma_e((T_n^*))^* \subset \Gamma_a \) or \( \Gamma_b \) is similar since \( T_n^* = T_0 - i\gamma s_n \).

Let \( \lambda \in \sigma_e((T_n)) \). Then there exist \( I \subset \mathbb{N} \) infinite and \( (u_n)_{n \in I} \subset D(T_0) \) with \( \|u_n\| = 1 \) for all \( n \in I \), \( u_n \to 0 \) and \( \|(T_n - \lambda)u_n\| = o(1) \). By Cauchy-Schwarz, we have
\[ \langle (T_n - \lambda)u_n, u_n \rangle = o(1) \], whose real and imaginary parts imply that
\[ \langle T_0u_n, u_n \rangle = \text{Re}(\lambda) + o(1) \quad \text{and} \quad \gamma \langle s_n u_n, u_n \rangle = \text{Im}(\lambda) + o(1). \]  
(2.14)

Since both \( (T_n u_n) \) and \( (s_n u_n) \) are bounded in \( \mathcal{H} \), \( (T_0 u_n) \) must be bounded in \( \mathcal{H} \). Hence by Cauchy-Schwarz we have \( \langle (T_n - \lambda)u_n, T_0 u_n \rangle = o(1) \), whose real part implies that
\[ \|T_0u_n\|^2 \text{Re}(\lambda) \langle T_0u_n, u_n \rangle - \gamma \text{Im}(s_n u_n, T_0 u_n) = o(1). \]  
(2.15)

The first equation in (2.14) gives
\[ \| (T_0 - \text{Re}(\lambda))u_n \|^2 = \|T_0u_n\|^2 - \text{Re}(\lambda) \langle T_0u_n, u_n \rangle + o(1), \]
which, combined with (2.15), yields,
\[ \| (T_0 - \text{Re}(\lambda))u_n \|^2 = \gamma \text{Im}(s_n u_n, T_0 u_n) + o(1). \]  
(2.16)

(a) In this case, \( \sigma(s_n) = \{0, 1\} \) so \( 0 \leq s_n \leq 1 \) for all \( n \), and so by the second equation in (2.14),
\[ \forall n \in I : \langle s_n u_n, u_n \rangle \in [0, 1] \quad \Rightarrow \quad \text{Im}(\lambda) \in [0, \gamma]. \]  
(2.17)

Focusing now on \( \text{Re}(\lambda) \), Cauchy-Schwarz gives us \( \langle (T_n - \lambda)u_n, s_n u_n \rangle = o(1) \), whose imaginary part combined with the hypothesis \( s_n^2 = s_n \) and the second equation in (2.14) gives,
\[ \text{Im} \langle s_n u_n, T_0 u_n \rangle = \gamma \|s_n u_n\|^2 - \text{Im}(\lambda) \langle s_n u_n, u_n \rangle + o(1) \]
\[ = (\gamma - \text{Im}(\lambda)) \frac{\text{Im}(\lambda)}{\gamma} + o(1). \]  
(2.18)

Combining (2.16) and (2.18), we have
\[ \| (T_0 - \text{Re}(\lambda))u_n \| = \sqrt{(\gamma - \text{Im}(\lambda)) \text{Im}(\lambda)} + o(1), \]  
(2.19)

which by Lemma 2.10 implies that
\[ \text{dist}(\text{Re}(\lambda), \sigma(e(T_0))) \leq \sqrt{(\gamma - \text{Im}(\lambda)) \text{Im}(\lambda)}. \]

(b) In this case, by the definitions of \( s_\pm \) in (2.11), a similar reasoning as in (2.17) yields \( \text{Im}(\lambda) \in \gamma [s_-, s_+] \). Assumption 2.11 implies that
\[ \text{Im} \langle s_n u_n, T_0 u_n \rangle = o(1) \quad \Rightarrow \quad \| (T_0 - \text{Re}(\lambda))u_n \| = o(1), \]
so \((u_n)\) is a singular sequence proving that \(\text{Re}(\lambda) \in \sigma_e(T_0)\).

\[\square\]

**Remark 2.13.** It is interesting to note that Lemma 2.10 is not required in case (b) of Theorem 2.12. This is because Assumption 2.11 ensures that the following holds:

\[(u_n) \subset D(T_n) = D(T_0), \|u_n\| = 1, u_n \to 0, \|(T_n - \lambda)u_n\| \to 0\]

\[\Rightarrow (u_n) \subset D(T_0), \|u_n\| = 1, u_n \to 0, \|(T_0 - \text{Re}(\lambda)u_n\| \to 0,\]

that is, if \((u_n)\) is a singular-type sequence for a point \(\lambda\) in the limiting essential spectrum then \((u_n)\) is also a singular sequence for \(\text{Re}(\lambda) \in \sigma_e(T_0)\).

**Example 2.14.** Suppose that \(T_0 = -\Delta + q\) is a self-adjoint Schrödinger operator on \(\mathcal{H} = L^2(\Omega)\), where \(\Omega \subset \mathbb{R}^d\) is some open set and \(q\) is a real function on \(\Omega\). Assume that \(T_0\) is endowed with Dirichlet boundary conditions on \(\partial\Omega\) and that \(q\) is bounded below. Let \(\varphi \in W^{1,\infty}(0, \infty)\) be real-valued and such that \(\varphi(0) = 1\). Let \((R_n) \subset \mathbb{R}_+\) be any sequence such that \(R_n \to \infty\). For any \(n \in \mathbb{N}\), define multiplication operator \(s_n\) on \(L^2(\Omega)\) by

\[(s_n u)(x) = \varphi\left(\frac{x}{R_n}\right) u(x) \quad (u \in L^2(\Omega), x \in \Omega) \quad (2.20)\]

where \(\langle x \rangle := (1 + |x|^2)^{\frac{1}{2}}\). Then \(s_n\) is uniformly bounded, \(s_n \rightharpoonup I\) and Assumption 2.11 is satisfied.

**Proof.** Define \(\varphi_n : \Omega \to \mathbb{R}\) by

\[\varphi_n(x) = \varphi\left(\frac{x}{R_n}\right) \quad (x \in \Omega)\]

**Step 1** (Uniform boundedness). The uniform boundedness of the sequence of operators \((s_n)\) follows from the fact that, for all \(u \in L^2(\Omega)\) and all \(n \in \mathbb{N}\),

\[\text{ess inf}_{t \in (0, \infty)} \|\varphi(t)\|^2 \leq \langle s_n u, u \rangle \leq \text{ess sup}_{t \in (0, \infty)} \varphi(t) \|u\|^2.\]

**Step 2** \((s_n \rightharpoonup I)\). Let \(u \in L^2(\Omega)\) and let \((X_n) \subset \mathbb{R}_+\) be any sequence such that \(X_n \to \infty\) and \(X_n = o(R_n)\). For any \(n \in \mathbb{N}\),

\[\|(s_n - I)u\| \leq \|\varphi(\cdot)/R_n\|_{L^\infty(\Omega \cap B_{X_n}(0))} \|u\| + (\|s_n\| + 1) \|u\|_{L^2(\Omega \setminus B_{X_n}(0))}. \quad (2.21)\]

By Morrey’s inequality, \(\varphi\) is continuous, so, since \(\varphi(0) = 1\), the first term on the right hand side of (2.21) tends to zero as \(n \to \infty\). The second term tends to zero because \(u \in L^2(\Omega)\) and \(\|s_n\|\) is bounded.
Step 3 (Assumption 2.11). Let \((u_n) \subset D(T_0)\) be any sequence which is bounded in \(\mathcal{H}\) such that \((T_0u_n)\) is bounded in \(\mathcal{H}\). Then,

\[
\langle s_n u_n, T_0 u_n \rangle - \langle T_0 u_n, s_n u_n \rangle = -\int_{\Omega} \nabla(\varphi_n) \cdot \nabla(u_n) + \int_{\Omega} \nabla(u_n) \Delta(\varphi_n).
\]

The second equality above holds by integration by parts and the product rule since \(T_0\) is endowed with Dirichlet boundary conditions. Hence we have,

\[
|\langle s_n u_n, T_0 u_n \rangle - \langle T_0 u_n, s_n u_n \rangle| \leq 2 \|\nabla \varphi_n\|_{L^\infty(\Omega)} \|\nabla u_n\| \|u_n\|. \tag{2.22}
\]

By the chain rule and the fact that \(\varphi \in W^{1,\infty}(0,\infty)\), \(\|\nabla \varphi_n\|_{L^\infty(\Omega)} \to 0\) as \(n \to \infty\). \((u_n)\) is bounded in \(\mathcal{H}\) by hypothesis. \((\nabla u_n)\) can be seen to be bounded in \(\mathcal{H}\) by applying integration by parts to \(\langle T_0 u_n, u_n \rangle\), using the hypotheses that \(\|T_0 u_n\|\) is bounded and that \(q\) is bounded below. The right hand side of (2.22) tends to zero as \(n \to \infty\) hence Assumption 2.11 is satisfied.

2.3 Second order operators on the half-line

Consider the differential expression

\[
\tilde{T}_0 u = \frac{1}{r} \left(-pu' + qu\right) \quad \text{on} \quad [0,\infty)
\]

where \(p, q\) and \(r\) are functions on \([0,\infty)\) satisfying the minimal hypotheses: \(p\) and \(q\) are complex in general, \(r > 0\), \(p \neq 0\) and \(q, 1/p, r \in L^1_{\text{loc}}[0,\infty)\). These assumptions on \(p, q\) and \(r\) ensure that for any \(\lambda, u_1, u_2 \in \mathbb{C}\) there exists a unique solution \(u\) to the initial value problem

\[
\tilde{T}_0 u = \lambda u \quad \text{on} \quad [0,\infty), \quad u(0) = u_1, \quad pu'(0) = u_2
\]

such that \(u, pu' \in AC_{\text{loc}}[0,\infty)\). The solution space of \(\tilde{T}_0 u = \lambda u\) on \([0,\infty)\) is therefore a two-dimensional complex vector space.

Consider a Sturm-Liouville operator \(T_0\) on the weighted Lebesgue space \(L^2_r(0,\infty)\), endowed with a complex mixed boundary condition at 0,

\[
BC[u] := \cos(\eta)u(0) - \sin(\eta)pu'(0) = 0 \quad \tag{2.23}
\]
for some $\eta \in \mathbb{C}$. $T_0$ is defined by

$$T_0u = \tilde{T}_0u$$

$$D(T_0) = \{ u \in L^2_r(0, \infty) : u, pu' \in AC_{\text{loc}}[0, \infty), \tilde{T}_0u \in L^2_r(0, \infty), BC[u] = 0 \}. \quad (2.24)$$

Fix $\gamma \in \mathbb{C} \setminus \{0\}$. Define the perturbed operators by

$$T_Ru = T_0u + i\gamma \chi_{[0,R]}u, \quad D(T_R) = D(T_0) \quad (R \in \mathbb{R}_+) \quad (2.25)$$

and define the limit operator by $T = T_0 + i\gamma$.

Next, we introduce the main hypotheses of this section, which we will later assume holds throughout the section. The assumption ensures that for any $\lambda \in \mathbb{C} \setminus \sigma_e(T_0)$, one solution of $\tilde{T}_0u = \lambda u$ is exponentially decaying and the other is exponentially growing.

**Assumption 2.15.** There exists $k : \mathbb{C} \setminus \sigma_e(T_0) \to \mathbb{C}$, $\tilde{\psi}_\pm : [0, \infty) \times \mathbb{C} \setminus \sigma_e(T_0) \to \mathbb{C}$ and $\tilde{\psi}_d^\pm : [0, \infty) \times \mathbb{C} \setminus \sigma_e(T_0) \to \mathbb{C}$ such that:

(i) $k$ is analytic and satisfies $\text{Im} k > 0$.

(ii) $\tilde{\psi}_\pm(x, \cdot)$ and $\tilde{\psi}_d^\pm(x, \cdot)$ are analytic for all $x$ and satisfy

$$\| \tilde{\psi}_\pm (\cdot, z) \|_{L^\infty(0, \infty)} < \infty, \quad \| \tilde{\psi}_d^\pm (\cdot, z) \|_{L^\infty(0, \infty)} < \infty \quad (2.26)$$

for all $z$.

(iii) The solution space of $\tilde{T}_0u = zu$ is spanned by $\psi_\pm(\cdot, z)$, where,

$$\psi_\pm(x, z) := e^{\pm ik(z)x} \tilde{\psi}_\pm(x, z)$$

$$\psi_d^\pm(x, z) := e^{\pm ik(z)x} \tilde{\psi}_d^\pm(x, z). \quad (2.27)$$

**Remark 2.16** (See [30]). The conditions of Assumption 2.15 do not exclude a situation in which $\sigma(T_0) = \sigma_e(T_0) = \mathbb{C}$. A sufficient condition to ensure that this does not occur is that

$$\overline{\text{co}} \left\{ \frac{q(x)}{r(x)} + yp(x) : x, y \in [0, \infty) \right\} \neq \mathbb{C},$$

where $\overline{\text{co}}$ denotes the closed convex hull, and that $\tilde{T}_0$ is in Sims case I (as defined in [30]).

**Example 2.17** (Schrödinger operators with $L^1$ potentials). Consider the case $p = r = 1$ with $q \in L^1(0, \infty)$. Then,

$$\sigma_e(T_0) = [0, \infty).$$
By the Levinson asymptotic theorem [60, Theorem 1.3.1], for any \( z \in \mathbb{C} \setminus \{0\} \), the solution space of \( \tilde{T}_0 u = zu \) is spanned by \( \psi_{\pm}(\cdot, z) \), where

\[
\psi_{\pm}(x, z) = e^{\pm i \sqrt{z} x}(1 + E_{\pm}(x, z)) \quad (2.28)
\]

and

\[
|E_{\pm}(x, z)|, |E_d^{\pm}(x, z)| \to 0 \text{ as } x \to \infty.
\]

(i) \( k(z) := \sqrt{z} \) is analytic and satisfies \( \text{Im} k > 0 \) on \( \mathbb{C} \setminus \sigma_e(\tilde{T}_0) = \mathbb{C} \setminus [0, \infty) \).

(ii) \( \tilde{\psi}_{\pm}(x, z) := 1 + E_{\pm}(x, z) \) and \( \tilde{\psi}_d^{\pm}(x, z) := \pm i \sqrt{z}(1 + E_d^{\pm}(x, z)) \) are bounded in \( x \) for any fixed \( z \in \mathbb{C} \setminus \{0\} \). For any \( x \), \( \psi_{\pm}(x, \cdot) \) and \( \psi_d^{\pm}(x, \cdot) \) are analytic on \( \mathbb{C} \setminus [0, \infty) \) so \( \psi_{\pm}(x, \cdot) \) and \( \psi_d^{\pm}(x, \cdot) \) are analytic on \( \mathbb{C} \setminus [0, \infty) \).

Consequently, Assumption 2.15 is satisfied in this case.

**Example 2.18** (Eventually periodic Schrödinger operators). Consider the case \( p = r = 1 \) with \( q \) eventually real periodic, that is, there exists \( a > 0 \) and \( X \geq 0 \) such that \( q|_{X, \infty} \) is real-valued and \( a \)-periodic. Below, we briefly review some Floquet theory and show that the conditions of Assumption 2.15 are met in this case. See, for example, [59] for a detailed exposition of Floquet theory.

For any \( z \in \mathbb{C} \), let \( \phi_1(\cdot, z) \) and \( \phi_2(\cdot, z) \) be the solutions of the Schrödinger equation \(-\phi'' + q\phi = z\phi \) on \([0, \infty)\), subject to the boundary conditions

\[
\phi_1(X, z) = 1, \phi'_1(X, z) = 0 \text{ and } \phi_2(X, z) = 0, \phi'_2(X, z) = 1. \quad (2.30)
\]

The discriminant is defined by

\[
\tilde{D}(z) = \phi_1(X + a, z) + \phi'_2(X + a, z). \quad (2.31)
\]

The essential spectrum of \( T_0 \) is

\[
\sigma_e(T_0) = \{ z \in \mathbb{R} : |\tilde{D}(z)| \leq 2 \}. \quad (2.32)
\]

The Floquet multipliers \( \rho_{\pm} \) are defined by

\[
\rho_{\pm}(z) = \frac{1}{2} \left( \tilde{D}(z) \pm i \sqrt{\tilde{D}(z)^2 - 4} \right). \quad (2.33)
\]
Note that \( \rho_{\pm} \) have branch cuts along \( \sigma_e(T_0) \), \( |\rho_{\pm}(z)| < 1 \) for all \( z \in \mathbb{C} \backslash \sigma_e(T_0) \) and \( \rho_{\pm}(z)\rho_{\mp}(z) = 1 \). Define \( k \) by

\[
k(z) = -\frac{i}{\rho_{\pm}(z)} \log(\rho_{\pm}(z)).
\] (2.34)

In this setting, \( k \) is referred to as the Floquet exponent. \( k \) is analytic and satisfies \( \text{Im} k > 0 \) on \( \mathbb{C} \backslash \sigma_e(T_0) \) hence satisfies Assumption (i).

Define the Floquet solutions \( \psi_{\pm} \) by

\[
\psi_{\pm}(x, z) = -\phi_2(X + a, z)\phi_1(x, z) + (\phi_1(X + a, z) - \rho_{\pm}(z))\phi_2(x, z)
\] (2.35)

for any \( x \in [0, \infty) \) and \( z \in \mathbb{C} \). \( \psi_{\pm}(\cdot, z) \) span the solution space of \( \tilde{T}_0u = zu \) and satisfy

\[
\psi_{\pm}(x_0 + na, z) = e^{\pm ik(z)na} \psi_{\pm}(x_0, z)
\] (2.36)

\[
\psi'_{\pm}(x_0 + na, z) = e^{\pm ik(z)na} \psi'_{\pm}(x_0, z)
\]

for any \( x_0 \in [X, X + a) \) and \( n \in \mathbb{N} \). For any \( x \), the Floquet solutions \( \psi_{\pm}(x, \cdot) \) and \( \psi'_{\pm}(x, \cdot) \) are analytic on \( \mathbb{C} \backslash \sigma_e(T_0) \). Define the band-ends \( B_{\text{ends}} \) by

\[
B_{\text{ends}} = \{ z \in \mathbb{R} : |D(z)| = 2 \}.
\] (2.37)

For any \( z_0 \in \sigma_e(T_0) \backslash B_{\text{ends}} \), \( \rho_{\pm} \) and \( k \) can be analytically continued into an open neighbourhood of \( z_0 \) in \( \mathbb{C} \), hence for any \( x \in [0, \infty) \), \( \psi_{\pm}(x, \cdot) \) and \( \psi'_{\pm}(x, \cdot) \) can be analytically continued into an open neighbourhood of \( z_0 \).

Finally, Assumption 2.15 can be satisfied by setting

\[
\tilde{\psi}_{\pm}(x, z) = \begin{cases} 
  e^{\mp ik(z)x} \psi_{\pm}(x, z) & \text{if } x \in [0, X) \\
  e^{\mp ik(z)x_0(x)} \psi_{\pm}(x_0(x), z) & \text{if } x \in [X, \infty)
\end{cases}
\] (2.38)

and

\[
\tilde{\psi}'_{\pm}(x, z) = \begin{cases} 
  e^{\mp ik(z)x} \psi'_{\pm}(x, z) & \text{if } x \in [0, X) \\
  e^{\mp ik(z)x_0(x)} \psi'_{\pm}(x_0(x), z) & \text{if } x \in [X, \infty)
\end{cases}
\] (2.39)

where \( x_0(x) := X + (x - X) \mod a \).

Throughout the remainder of the section, let

\[
S := \sigma_e(T_0) \cup (i\gamma + \sigma_e(T_0))
\] (2.40)
and suppose that the conditions of Assumption 2.15 are satisfied. Also, let \((R_n) \subset \mathbb{R}_+\) be any sequence such that \(R_n \to \infty\) as \(n \to \infty\). Recall that \(BC\) denotes the boundary condition functional defined by equation (2.23).

**Lemma 2.19.** \(\lambda \in \mathbb{C}\setminus S\) is an eigenvalue of \(T_R\) if and only if

\[
f_R(\lambda) := \alpha_+(R, \lambda) e^{ik(\lambda - i\gamma)R} + \alpha_-(R, \lambda) e^{-ik(\lambda - i\gamma)R} = 0
\]

where

\[
\alpha_+(R, \lambda) := BC[\psi_-(\cdot, \lambda - i\gamma)] \left( \tilde{\psi}_+(R, \lambda) \tilde{\psi}_+^d(R, \lambda) - \tilde{\psi}_+^d(R, \lambda - i\gamma) \tilde{\psi}_+(R, \lambda) \right)
\]

and

\[
\alpha_-(R, \lambda) := BC[\psi_+(\cdot, \lambda - i\gamma)] \left( \tilde{\psi}_+(R, \lambda) \tilde{\psi}_-^d(R, \lambda) - \tilde{\psi}_-^d(R, \lambda - i\gamma) \tilde{\psi}_-(R, \lambda - i\gamma) \right).
\]

Furthermore, \(f_R\) is analytic on \(\mathbb{C}\setminus S\).

**Proof.** Let \(\lambda \in \mathbb{C}\setminus S\) and \(R > 0\). \(\lambda\) is an eigenvalue of \(T_R\) if and only if there exists a solution to the problem

\[
(\tilde{T}_0 + i\gamma \chi_{[0,R]})u = \lambda u, \quad BC[u] = 0, \quad u \in L^2_r(0, \infty), \quad (2.41)
\]

on \([0, \infty)\). Any solution to (2.41) on \([0,R]\) must be of the form \(C_1 u_1(\cdot, \lambda)\), where \(u_1\) is defined by

\[
u_1(x, \lambda) = BC[\psi_-(\cdot, \lambda - i\gamma)] \psi_+(x, \lambda - i\gamma) - BC[\psi_+(\cdot, \lambda - i\gamma)] \psi_-(x, \lambda - i\gamma)
\]

and \(C_1 \in \mathbb{C}\) is independent of \(x\). Any solution to (2.41) on \([R, \infty)\) must be of the form \(C_2 \psi_+(x, \lambda)\), where \(C_2 \in \mathbb{C}\) is independent of \(x\). Hence \(\lambda\) is an eigenvalue if and only if there exists \(C_1, C_2 \in \mathbb{C}\setminus \{0\}\) independent of \(x\) such that the function

\[
x \mapsto \begin{cases} 
C_1 u_1(x, \lambda) & \text{if } x \in [0,R) \\
C_2 \psi_+(x, \lambda) & \text{if } x \in [R, \infty)
\end{cases}
\]

is absolutely continuous. This holds if and only if

\[
u_1(R, \lambda) \psi'_+(R, \lambda) - u_1'(R, \lambda) \psi_+(R, \lambda) = 0
\]
which holds if and only if the following quantity is zero

\[
(BC[\psi_-(\cdot, \lambda - i\gamma)]\psi_+(R, \lambda - i\gamma) - BC[\psi_+(\cdot, \lambda - i\gamma)]\psi_-(R, \lambda - i\gamma))\tilde{\psi}_d^d(R, \lambda)
- (BC[\psi_-(\cdot, \lambda - i\gamma)]\psi'_+(R, \lambda - i\gamma) - BC[\psi_+(\cdot, \lambda - i\gamma)]\psi'_-(R, \lambda - i\gamma))\tilde{\psi}_+(R, \lambda)
\]

which in turn is equivalent to \(f_R(\lambda) = 0\). The analyticity claim follows from Assumptions 2.15 (i) and (ii).

In the regions of the complex plane for which \(\alpha_- (R, \cdot)\) becomes small for large \(R\), we are unable to prove the spectral pollution and spectral inclusion results of Theorems 2.23 and 2.24. We now define a subset of the complex plane capturing such regions.

**Definition 2.20.** Define subset \(S_p((R_n))\) of \(\mathbb{C}\) by

\[
S_p((R_n)) = \left\{ z \in \mathbb{C} \setminus S : \liminf_{n \to \infty} |\Lambda(R_n, z)| = 0 \right\}
\]  

(2.42)

where the function \(\Lambda : [0, \infty) \times \mathbb{C} \setminus S \to \mathbb{C}\) is defined by

\[
\Lambda(R, \lambda) = \tilde{\psi}_+(R, \lambda)\tilde{\psi}_d^d(R, \lambda - i\gamma) - \tilde{\psi}_+(R, \lambda)\tilde{\psi}_-(R, \lambda - i\gamma).
\]  

(2.43)

Note that with the above definition of \(\Lambda\), we have

\[
\alpha_- (R, \lambda) = BC[\psi_+(\cdot, \lambda - i\gamma)]\Lambda(R, \lambda)
\]

and that the zeros of \(\lambda \mapsto BC[\psi_+(\cdot, \lambda - i\gamma)]\Lambda(R, \lambda)\) are exactly the eigenvalues of the limit operator \(T = T_0 + i\gamma\).

The set \(S \cup S_p((R_n))\) plays a similar role in this section as the limiting essential spectrum did in Section 2.2. We shall show in Theorems 2.23 and 2.24 that there is no spectral pollution for \((T_{R_n})\) with respect to \(T\) outside of \(S \cup S_p((R_n))\) and that eigenvalues of \(T\) lying outside of \(S \cup S_p((R_n))\) are approximated (with exponentially small error) by the eigenvalues of \(T_{R_n}\).

**Proposition 2.21.** \(S \cup S_p((R_n))\) is a closed subset of \(\mathbb{C}\).

**Proof.** By Assumption 2.15 (ii), \(\Lambda(R_n, \cdot)\) is analytic for all \(n\) and \(\Lambda(\cdot, z)\) is bounded for all \(z\). Let \(\lambda\) be a limit point of \(S \cup S_p((R_n))\). The desired lemma holds if and only if \(\lambda\) lies in either \(S\) or in \(S_p((R_n))\). If \(\lambda\) is a limit point of \(S\) then \(\lambda \in S\) since \(S\) is closed. In the only other case, \(\lambda\) is a limit point of \(S_p((R_n))\) so there exists \((\lambda_k) \subset S_p((R_n))\) such that \(\lambda_k \to \lambda\) as \(k \to \infty\). Since \(\liminf_{n \to \infty} |\Lambda(R_n, \lambda_k)| = 0\) for all \(k\), there exists a subsequence \((R_{n_k})\) such that \(|\Lambda(R_{n_k}, \lambda_k)| \to 0\) as \(k \to \infty\). Let \(\varepsilon > 0\) be small enough so
Then there exists eigenvalues \( \lambda \) of \( R \). Since the magnitude of \( \Lambda(R, z) \) is bounded above uniformly for all \( R > 0 \) and all \( z \in B_e(\lambda) \), by Cauchy’s formula,

\[
\Lambda(R_{n_k}, \lambda) - \Lambda(R_{n_k}, \lambda_k) = \frac{1}{2\pi i} \oint_{\partial B_e(\lambda)} \frac{\lambda_k - \lambda}{(z - \lambda)(z - \lambda_k)} \Lambda(R_{n_k}, z) \, dz \to 0
\]

as \( k \to \infty \). Finally,

\[
|\Lambda(R_{n_k}, \lambda)| \leq |\Lambda(R_{n_k}, \lambda_k)| + |\Lambda(R_{n_k}, \lambda) - \Lambda(R_{n_k}, \lambda_k)| \to 0 \text{ as } k \to \infty
\]

so \( \lambda \in S_p((R_n)) \), completing the proof. \( \square \)

**Corollary 2.22.** For any \( \lambda \in \mathbb{C}\setminus(S \cup S_p((R_n))) \) there exists a bounded, open neighbourhood \( U \) of \( \lambda \) with \( \overline{U} \subset \mathbb{C}\setminus(S \cup S_p((R_n))) \) and \( |\Lambda(R_n, z)| \geq C \) for all \( n \) such that \( C, N_0 > 0 \) are some constants independent of \( n \) and \( z \).

**Proof.** Let \( \lambda \in \mathbb{C}\setminus(S \cup S_p((R_n))) \). \( \mathbb{C}\setminus(S \cup S_p((R_n))) \) is an open subset of \( \mathbb{C} \) so there exists a bounded open neighbourhood \( U \) of \( \lambda \) such that \( \overline{U} \subset \mathbb{C}\setminus(S \cup S_p((R_n))) \). Suppose that the desired result does not hold with this choice for \( U \). Then there exists a subsequence \( (R_{n_k}) \) and a sequence \( (z_k) \subset U \) such that \( |\Lambda(R_{n_k}, z_k)| \to 0 \) as \( k \to \infty \). Since \( \overline{U} \) is compact, there exists \( z \in \mathbb{C}\setminus(S \cup S_p((R_n))) \) such that \( z_k \to z \). By the arguments in (a), \( \liminf_{n \to \infty} |\Lambda(R_n, z)| = 0 \), which is the desired contradiction. \( \square \)

Next, we prove the main results of this section, regarding spectral inclusion and pollution for the operators \( T_R \) defined by equation (2.25) such that \( T_0 \) satisfies Assumption 2.15. Recall that \( S \) is defined by equation (2.40), \( S_p((R_n)) \) is defined by (2.42) and \( (R_n) \subset \mathbb{R}_+ \) is an arbitrary sequence such that \( R_n \to \infty \).

**Theorem 2.23.** Let \( \mu \) be an eigenvalue of \( T_0 \) and assume that \( \mu + i\gamma \notin S \cup S_p((R_n)) \). Then there exists eigenvalues \( \lambda_n \) of \( T_{R_n} \) (\( n \) large enough) and constants \( C_0 = C_0(\mu, \gamma, \lambda) > 0 \) and \( \beta = \beta(\mu, \gamma, \mu) > 0 \) such that

\[
|\lambda_n - (\mu + i\gamma)| \leq C_0 e^{-\beta R_n}
\]

for all large enough \( n \).

**Proof.** Let \( C > 0 \) denote an arbitrary constant independent of \( \lambda \) and \( n \). Let \( C_1, C_2, C_3, N_0 > 0 \) denote constants independent of \( \lambda \) and \( n \).

Since \( \mu \) is an eigenvalue of \( T_0 \), \( \mu + i\gamma \) is a zero of the analytic function

\[
\lambda \mapsto \tilde{f}(\lambda) := BC[\psi_+ (\cdot, \lambda - i\gamma)].
\]
Since it is assumed that $\mu + i\gamma \notin S \cup S_p((R_n))$, Corollary 2.22 guarantees the existence of an open neighbourhood $U$ of $\mu + i\gamma$ such that $U \subseteq C \setminus S$ and $|\Lambda(R_n, \lambda)| \geq C (\lambda \in U, n \geq N_0)$ for some sufficiently large $N_0 \in \mathbb{N}$. For $n \geq N_0$, $\lambda \in U$ is an eigenvalue of $T_{R_n}$ if and only if
\[ \tilde{f}_n(\lambda) := e^{i(\lambda - i\gamma)R_n} \frac{f_{R_n}(\lambda)}{\Lambda(R_n, \lambda)} = 0. \]

Since $U \subseteq C \setminus S$, Assumption 2.15 guarantees that $|\alpha_+(R_n, \lambda)| \leq C (\lambda \in U, n \in \mathbb{N})$ and $\text{Im}(\lambda - i\gamma) \geq C (\lambda \in U)$. Combined with the bound below for $\Lambda$, this implies that
\[ |\tilde{f}_n(\lambda) - f(\lambda)| = \left| e^{2i(\lambda - i\gamma)R_n} \frac{\alpha_+(R_n, \lambda)}{\Lambda(R_n, \lambda)} \right| \leq C_1 e^{-C_2R_n} \quad (\lambda \in U, n \geq N_0) \tag{2.46} \]
for some $C_1, C_2 > 0$. Since $\tilde{f}$ is analytic at $\mu + i\gamma$, there exists $\varepsilon > 0$ such that
\[ |\tilde{f}(\lambda)| \geq C_3 |\lambda - (\mu + i\gamma)|^\nu \quad (\lambda \in B_\varepsilon(\mu + i\gamma)) \tag{2.47} \]
for some $C_3 > 0$. Here, $\nu$ is the algebraic multiplicity of the eigenvalue $\mu$ of $T_0$, that is, the multiplicity of the zero $\mu$ of the analytic function $z \mapsto B.C[\psi_+(\cdot, z)]$. Let $C_0 = (2C_1/C_3)^{1/\nu}$ and $\beta = C_2/\nu$. Make $N_0 \in \mathbb{N}$ large enough such that $C_0 e^{-\beta R_n} < \varepsilon (n \geq N_0)$. Combining (2.46) and (2.47), for all $n \geq N_0$ and all $\lambda \in C$ with
\[ |\lambda - (\mu + i\gamma)| = C_0 e^{-\beta R_n} \]
we have
\[ |\tilde{f}_n(\lambda) - \tilde{f}(\lambda)| \leq \frac{1}{2} |\tilde{f}(\lambda)| < |\tilde{f}(\lambda)|. \]

By Rouché’s theorem, for all $n \geq N_0$ there exists a zero $\lambda_n \in U$ of $\tilde{f}_n$ satisfying inequality (2.45).

The next result concerns spectral pollution - the set of spectral pollution is defined by equation (2.4).

**Theorem 2.24.** The set of spectral pollution of the sequence of operators $(T_{R_n})$ with respect to the limit operator $T = T_0 + i\gamma$ satisfies
\[ \sigma_{\text{poll}}((T_{R_n})) \subseteq \sigma_{\text{e}}(T_0) \cup S_p((R_n)). \]

**Proof.** Let $C > 0$ denote an arbitrary constant independent of $\lambda$ and $n$.

Let $\mu \in C \setminus (S \cup S_p((R_n)))$ and assume that $\mu$ is not an eigenvalue of $T$. Then $\mu$ is an arbitrary element of $\rho(T) \setminus (\sigma_{e}(T_0) \cup S_p((R_n)))$. We aim to show that $\mu \notin \sigma_{\text{poll}}((T_{R_n}))$. 

for which it suffices to show that there exists a neighbourhood $U$ of $\mu$ such that $f_{R_n}$ has no zeros in $U$ for large enough $n$.

Since $\mu \notin S_p((R_n))$ and $BC[\psi_\cdot(\cdot,\mu - i\gamma)] \neq 0$,

$$|\alpha_-(R_n,\mu)| = |BC[\psi_\cdot(\cdot,\mu - i\gamma)]\Lambda(R_n,\mu)| \geq C$$

(2.48)

for large enough $n$. Let $\varepsilon > 0$ be small enough so that $B_\varepsilon(\mu) \subseteq C \setminus S$. Then by Assumption 2.15 we have

$$|\alpha_\pm(R_n,\lambda)| \leq C \text{ and } \text{Im}(\lambda - i\gamma) \geq C \quad (\lambda \in B_\varepsilon(\mu), n \in \mathbb{N})$$

(2.49)

Using Cauchy’s integral formula as in (2.44), and making $\varepsilon > 0$ small enough, we have

$$|\alpha_\pm(R_n,\lambda) - \alpha_\pm(R_n,\mu)| \leq C|\lambda - \mu| \quad (\lambda \in B_\varepsilon(\mu), n \in \mathbb{N}).$$

(2.50)

Define approximation $f_n^{(\mu)}$ to $f_{R_n}$ by

$$f_n^{(\mu)}(\lambda) := \alpha_+(R_n,\mu)e^{ik(\lambda - i\gamma)R_n} + \alpha_-(R_n,\mu)e^{-ik(\lambda - i\gamma)R_n}.$$ 

By (2.50) we have

$$|f_{R_n}(\lambda) - f_n^{(\mu)}(\lambda)| \leq C|\lambda - \mu|e^{\text{Im}(\lambda - i\gamma)R_n} \quad (\lambda \in B_\varepsilon(\mu), n \in \mathbb{N}).$$

Using (2.48) and (2.49) we have

$$|e^{ik(\lambda - i\gamma)R_n}f_n^{(\mu)}(\lambda)| \geq \frac{|\alpha_-^2(R_n,\mu)| - |\alpha_+^2(R_n,\mu)|e^{-2\text{Im}(\lambda - i\gamma)R_n}}{2} \geq C \quad (\lambda \in B_\varepsilon(\mu))$$

for large enough $n$. Finally, making $\varepsilon > 0$ small enough if necessary, we have

$$|f_{R_n}(\lambda) - f_n^{(\mu)}(\lambda)| < |f_n^{(\mu)}(\lambda)| \quad (\lambda \in B_\varepsilon(\mu))$$

for large enough $n$. $f_{R_n}$ therefore has no zeros in $U := B_\varepsilon(\mu)$ for large enough $n$, completing the proof.

In the case of Schrödinger operators on $L^2(0,\infty)$ with $L^1$ potentials, described in Example 2.17, $S_p((R_n))$ can be easily shown to be the empty set.
2.3 Second order operators on the half-line

Example 2.25 (Schrödinger operators with $L^1$ potentials, continued). Consider again the case $p = r = 1$ with $q \in L^1(0, \infty)$. Then, using expression (2.43) for $\Lambda$ and the expressions for $\tilde{\psi}_\pm, \tilde{\psi}_\pm'$ in Example 2.17 (ii), $\Lambda$ satisfies

$$\Lambda(R, \lambda) \to -i\left(\sqrt{\lambda - i\gamma} + \sqrt{\lambda}\right) \text{ as } R \to \infty$$

for any $\lambda \in \mathbb{C} \setminus S$. Since $\sqrt{\lambda - i\gamma} \neq -\sqrt{\lambda}$ for all $\lambda \in \mathbb{C}$ we have

$$S_p((R_n)) = \emptyset$$

for any $(R_n) \subset \mathbb{R}_+$ with $R_n \to \infty$ as $n \to \infty$.

For Schrödinger operators with eventually real periodic potentials, described in Example 2.18, the computation of $S_p((R_n))$ is more involved.

Example 2.26 (Eventually periodic Schrödinger operators, continued). Consider again the case $p = r = 1$ with $q_{|_{[X, \infty)}}$ real-valued and $a$-periodic for some $X \geq 0$ and $a > 0$. Assume that $\gamma > 0$ and let $R_n = x_0 + na (n \in \mathbb{N})$ for any fixed $x_0 \in [X, X + a]$.

Using the expressions (2.38) and (2.39) for $\tilde{\psi}_\pm$ and $\tilde{\psi}_\pm'$ as well as the definition of $S_p((R_n))$ in equation (2.42), we infer that $\lambda \in S_p((R_n))$ if and only if

$$\psi_+(x_0, \lambda) \psi'_-(x_0, \lambda - i\gamma) - \psi_+'(x_0, \lambda) \psi_-(x_0, \lambda - i\gamma) = 0. \quad (2.51)$$

$\psi_\pm(x_0, \cdot)$ and $\psi_\pm'(x_0, \cdot)$ are analytic on $\mathbb{C} \setminus \sigma_e(T_0)$ and can be analytically continued into an open neighbourhood in $\mathbb{C}$ of any point in $\sigma_e(T_0) \setminus B_{\text{ends}}$ (recall that $B_{\text{ends}}$ denotes the set of band-ends for the essential spectrum of $T_0$). Consequently, $S_p((R_n))$ consists of isolated points in the complex plane that can only accumulate to the band-ends of either $T_0$ or $T$, that is, to the set $B_{\text{ends}} \cup (i\gamma + B_{\text{ends}})$.

Recall that $\sigma_e((T_{R_n}))$ denotes the limiting essential spectrum of the sequence of operators $(T_{R_n})$. $S_p((R_n))$ satisfies the inclusion

$$S_p((R_n)) \subseteq \sigma_e((T_{R_n})). \quad (2.52)$$

Proof of inclusion (2.52). Throughout the proof, $C > 0$ denotes an arbitrary constant independent of $n$.

By $\| \cdot \|_{L^2}$ and $\| \cdot \|_{L^\infty}$, we mean $\| \cdot \|_{L^2(0, \infty)}$ and $\| \cdot \|_{L^\infty(0, \infty)}$ respectively.

Let $\lambda \in S_p((R_n))$. Then, using the property (2.36) of the Floquet solutions, (2.51) implies that,

$$\psi_+(R_n, \lambda) \psi'_-(R_n, \lambda - i\gamma) - \psi_+'(R_n, \lambda) \psi_-(R_n, \lambda - i\gamma) = 0 \quad (2.53)$$
for all $n$. (2.53) ensures that there exists $C_{1,n}, C_{2,n} \in \mathbb{C} \setminus \{0\}$ independent of $x$ such that

$$u_n(x) := \begin{cases} C_{1,n} \psi_-(x, \lambda - i\gamma) & \text{if } x \in [0, R_n) \\ C_{2,n} \psi_+(x, \lambda) & \text{if } x \in [R_n, \infty) \end{cases}$$  (2.54)

is absolutely continuous and solves the Schrödinger equation $\tilde{T}_{R_n} u = \lambda u$, where $\tilde{T}_{R_n}$ denotes the differential expression on $[0, \infty)$ corresponding to $T_{R_n}$. Define

$$v_n = \frac{\tilde{\chi}_n u_n}{\|\tilde{\chi}_n u_n\|_{L^2}}.$$ 

where $\tilde{\chi}_n(x) := \tilde{\chi}(x/R_n)$ and $\tilde{\chi} : [0, \infty) \to [0, 1]$ is any smooth function such that $\tilde{\chi} = 0$ on $[0, \frac{1}{2}]$ and $\tilde{\chi} = 1$ on $[\frac{1}{2}, \infty)$. Then $v_n \in D(T_0) = D(T_{R_n})$, $\|v_n\|_{L^2} = 1$ and, since $\langle v_n, \varphi \rangle_{L^2} = 0$ for any $\varphi \in C_c^\infty(0, \infty)$ and any large enough $n$, $v_n \rightharpoonup 0$ in $L^2(0, \infty)$.

By unique continuation,

$$\|\psi'_- (\cdot, \lambda - i\gamma)\|_{L^2(I)} \leq C\|\psi_-(\cdot, \lambda - i\gamma)\|_{L^2(I)}$$

for $I = [0, X]$, $[X, X + a]$ or $[X, x_0]$ so, using the property (2.36) of the Floquet solutions

$$\|\psi'_- (\cdot, \lambda - i\gamma)\|_{L^2(0, R_n)}^2 \leq C\|\psi_-(\cdot, \lambda - i\gamma)\|_{L^2(0, R_n)}^2$$

(2.55) for all $n$. Also, noting that $\|\psi_-(\cdot, \lambda - i\gamma)\|_{L^2(0, x)}$ is exponentially growing in $x$, we deduce that,

$$\|u_n\|_{L^2} \leq C\|u_n\|_{L^2(\frac{1}{2} R_n, \infty)} \leq C\|\tilde{\chi}_n u_n\|_{L^2}.$$  (2.56)

for all large enough $n$.

By the product rule,

$$\|(T_{R_n} - \lambda)v_n\|_{L^2} \leq \frac{1}{\|\tilde{\chi}_n u_n\|_{L^2}} \left[ \|\tilde{\chi}_n (T_{R_n} - \lambda) u_n\|_{L^2} + 2\|\tilde{\chi}_n' u'_n\|_{L^2} + \|\tilde{\chi}_n'' u_n\|_{L^2} \right].$$

The first term in the square brackets above vanishes and $\tilde{\chi}_n^{(k)}$ are supported in $[0, R_n]$ with $\|\tilde{\chi}_n^{(k)}\|_{L^\infty} \leq C/R_n^k$ so

$$\|(T_{R_n} - \lambda)v_n\|_{L^2} \leq C\frac{\|u_n\|_{L^2}}{\|\tilde{\chi}_n u_n\|_{L^2}} \left[ \frac{1}{R_n} \|\psi'_- (\cdot, \lambda - i\gamma)\|_{L^2(0, R_n)}^2 + \frac{1}{R_n^2} \right] \to 0 \text{ as } n \to \infty.$$ 

Here, we used estimates (2.55) and (2.56). Consequently, by the definition of limiting essential spectrum (see Definition 2.1), we have $\lambda \in \sigma_e((T_{R_n}))$. 

\[\square\]
Consider the Sturm-Liouville operator $T_0$ introduced in Section 2.3. Suppose that the conditions of Assumption 2.15 are met. As before, fix $\gamma \in \mathbb{C}\setminus\{0\}$, define the perturbed operators by

$$T_R u = T_0 u + i\gamma \chi_{[0,R]} u, \quad D(T_R) = D(T_0) \quad (R \in \mathbb{R}_+),$$

and define the limit operator by $T = T_0 + i\gamma$.

In this section, we prove that the essential spectrum of the limit operator $T$ is approximated by the eigenvalues of $T_R$ as $R \to \infty$. To achieve this, we require an additional assumption which ensures that the solution $\psi_+$ of $\tilde{T}_0 u = \lambda u$ introduced in Assumption 2.15 can be analytically continued, with respect to the spectral parameter $\lambda$, into an open neighbourhood in $\mathbb{C}$ of any point in the interior of $\sigma_e(T_0)$. The interior of the essential spectrum is denoted by $\text{int}(\sigma_e(T_0))$ and defined with respect to the subspace topology.

**Assumption 2.27.** $T_0$ is such that $\sigma_e(T_0) \subseteq \mathbb{R}$. For any $\mu \in \text{int}(\sigma_e(T_0))$, there exists an open neighbourhood $V_\mu$ of $\mu$ such that:

(i) $k$ admits analytic continuations $\kappa_u (\kappa_l)$ from the half-planes $\mathbb{C}_+ (\mathbb{C}_-)$ respectively into $V_\mu$, with

$$\text{Im} \kappa_u(z), \text{Im} \kappa_l(z) \begin{cases} 
> 0 & \text{if } z \in \mathbb{C}_+ \cap V_\mu \\
= 0 & \text{if } z \in \mathbb{R} \cap V_\mu \\
< 0 & \text{if } z \in \mathbb{C}_- \cap V_\mu
\end{cases} \quad (2.57)$$

(ii) For any $R > 0$, $\tilde{\psi}_+ (R, \cdot)$ admits analytic continuations $\tilde{\phi}_u (R, \cdot) (\tilde{\phi}_l (R, \cdot))$ from $\mathbb{C}_+ (\mathbb{C}_-)$ respectively into $V_\mu$ and $\tilde{\psi}_d^d (R, \cdot)$ admits analytic continuations $\tilde{\phi}_u^d (R, \cdot) (\tilde{\phi}_l^d (R, \cdot))$ from $\mathbb{C}_+ (\mathbb{C}_-)$ respectively into $V_\mu$. $\tilde{\phi}_j$ and $\tilde{\phi}_j^d$ satisfy

$$\| \tilde{\phi}_j(\cdot, z) \|_{L^\infty(0, \infty)} , \| \tilde{\phi}_j^d(\cdot, z) \|_{L^\infty(0, \infty)} < \infty \quad (j = u \text{ or } l) \quad (2.58)$$

for all $z \in V_\mu$.

(iii) For each $z \in V_\mu$, the functions $\varphi_u (\cdot, z)$ and $\varphi_l (\cdot, z)$, defined by

$$\varphi_j(x, z) := e^{i\kappa_j(x)z} \tilde{\phi}_j(x, z) \quad (j = u \text{ or } l), \quad (2.59)$$
solve the equation $\tilde{T}_0 \phi = z \phi$ and satisfy

$$\phi'_j(x, z) = e^{ix_j(z)x} \tilde{\phi}_j^d(x, z). \quad (j = u \text{ or } l)$$  \hfill (2.60)

In the following two examples, by analytic continuations we mean analytic continuations from $C_+$ and $C_-$ into $V_\mu$.

**Example 2.28** (Schrödinger operators with $L^1$ potentials, continued). Consider again the case $p = r = 1$ with $q \in L^1(0, \infty)$, introduced in Example 2.17. Recall that $k(\lambda) = \sqrt{\lambda}$ so Assumption 2.27 (i) is satisfied in this case. Recall that

$$\tilde{\psi}_\pm(x, z) = 1 \pm E_\pm(x, z)$$

and

$$\tilde{\psi}_\pm^d(x, z) = \pm i \sqrt{z} (1 + E^d_\pm(x, z)).$$

In order to show that Assumption 2.27 (ii) and (iii) hold in this case it suffices to show that for any $\mu \in \text{int}(\sigma_{\tilde{T}_0})$ and any $x \in [0, \infty)$, $E_+(x, \cdot)$ and $E^d_+(x, \cdot)$ admit analytic continuations $E(x, \cdot)$ and $E^d(x, \cdot)$ (respectively) into an open neighbourhood $V_\mu$ of $\mu$ independent of $x$, such that the function $\varphi(\cdot, z)$ defined by

$$\varphi(x, z) := e^{i \sqrt{z} x}(1 + E(x, z))$$  \hfill (2.61)

satisfies

$$\varphi'(x, z) = i \sqrt{z} e^{i \sqrt{z} x} \left(1 + E^d(x, z)\right),$$  \hfill (2.62)

solves the Schrödinger equation $-\varphi'' + q \varphi = z \varphi$ and satisfies

$$|E_\pm(x, z)|, |E^d_\pm(x, z)| \to 0 \text{ as } x \to \infty$$

for any fixed $z \in V_\mu$. Note that $\sqrt{\cdot}$ is understood to have been analytically continued into $V_\mu$ in (2.61) and (2.62). Additional conditions on the potential $q$ are required to ensure that this holds. Two such conditions are:

(a) (Naimark condition [131, Lemma 1]) There exists $a > 0$ such that

$$\int_0^\infty e^{ax} |q(x)| dx < \infty.$$  \hfill (2.63)

(b) (Dilation analyticity [29]) $q$ is real-valued and can be analytically continued into some open, convex region $U \subset \mathbb{C}$ containing a sector $\{ z \in \mathbb{C} : \arg(z) \in [-\theta, \theta] \}$ for some $\theta \in (0, \frac{\pi}{2}]$. Furthermore, there exists $C_0 > 0$ and $\beta > 1$ independent of $z$ such that

$$|q(z)| \leq C_0 |z|^{-\beta}$$  \hfill (2.64)

for all $z \in U$. 
Example 2.29 (Eventually periodic Schrödinger operators, continued). Consider again the case $p = r = 1$ with $q$ eventually real periodic, introduced in Example 2.18. As mentioned in Example 2.18, for any $\mu \in \text{int}(\sigma_{e}(T_{0})) = \sigma_{e}(T_{0}) \setminus B_{\text{ends}}$ and any $x \in [0, \infty)$, the functions $k$, $\psi_{+}(x, \cdot)$ and $\psi'_{+}(x, \cdot)$ admit analytic continuations into an open neighbourhood $V_{\mu}$ of $\mu$.

(i) By the expression (2.33) for $\tilde{\rho}_{+}$, the analytic continuations $\tilde{\rho}_{+}$ for $\rho_{+}$, from $C_{\pm}$ into $V_{\mu}$, satisfies

$$|	ilde{\rho}_{+}| \begin{cases} 
< 1 & \text{if } z \in C_{\pm} \cap V_{\mu} \\
= 1 & \text{if } z \in \mathbb{R} \cap V_{\mu} \\
> 1 & \text{if } z \in C_{\mp} \cap V_{\mu}
\end{cases}.$$ 

Hence, the analytic continuations of $k$ satisfy equation (2.57).

(ii) The analytic continuations of $\tilde{\psi}_{+}(x, \cdot)$ and $\tilde{\psi}'_{+}(x, \cdot)$ satisfy the $L^\infty$ estimates (2.58) by their definitions (2.38) and (2.39).

(iii) The analytic continuations with respect to $z$ of $\psi_{+}(\cdot, z)$ solve the Schrödinger equation $-\psi'' + q \psi = z \psi$ since by (2.35) they are linear combinations of the solutions $\phi_{1}(\cdot, z)$ and $\phi_{2}(\cdot, z)$. Expressions (2.59) and (2.60) for the analytic continuations of $\psi_{+}$ and $\psi'_{+}$ hold by the definition of (the analytic continuations of) $\tilde{\psi}_{+}$ and $\tilde{\psi}'_{+}$ respectively.

Throughout the remainder of the section, let $\mu \in \text{int}(\sigma_{e}(T_{0}))$ and suppose that the conditions of Assumption 2.27 are satisfied. Also, assume without loss of generality that $(i \gamma + V_{\mu}) \cap \mathbb{R} = \emptyset$.

Lemma 2.30. $\lambda \in i \gamma + V_{\mu}$ is an eigenvalue of $T_{R}$ if and only if

$$g_{R}(\lambda) := \beta_{u}(R, \lambda) e^{i\kappa_{u}(\lambda - i \gamma)R} + \beta_{l}(R, \lambda) e^{i\kappa_{l}(\lambda - i \gamma)R} = 0$$

where

$$\beta_{u}(R, \lambda) := BC[\phi(\cdot, \lambda - i \gamma)]\left( \tilde{\phi}_{u}(R, \lambda) - \tilde{\phi}'_{u}(R, \lambda) \tilde{\psi}_{+}(R, \lambda) \right)$$

and

$$\beta_{l}(R, \lambda) := BC[\phi(\cdot, \lambda - i \gamma)]\left( \tilde{\phi}_{+}(R, \lambda) \tilde{\phi}'_{u}(R, \lambda) - \tilde{\psi}'_{+}(R, \lambda) \tilde{\phi}_{l}(R, \lambda - i \gamma) \right).$$

Furthermore, $g_{R}$ is analytic on $i \gamma + V_{\mu}$.

Proof. The proof is similar to the proof of Lemma 2.19.
Let $\lambda \in i\gamma + V_\mu$. Any solution of the boundary value problem

$$(\tilde{T}_0 + i\gamma \chi_{[0,R]})u = \lambda u \text{ on } [0,R], \quad BC[u] = 0,$$

must lie in $\text{span}_\mathbb{C}\{u_1(\cdot, \lambda)\}$, where $u_1$ is defined by

$$u_1(x, \lambda) = BC[\psi_1(\cdot, \lambda - i\gamma)]\varphi_u(x, \lambda - i\gamma) - BC[\varphi_u(\cdot, \lambda - i\gamma)]\psi_1(x, \lambda - i\gamma).$$

Since $(i\gamma + V_\mu) \cap \mathbb{R} = \emptyset$, any $L^2$ solution of $(\tilde{T}_0 + i\gamma \chi_{[0,R]})u = \lambda u \text{ on } [R, \infty)$ must lie in $\text{span}_\mathbb{C}\{\psi_+(\cdot, \lambda)\}$. $\lambda$ is an eigenvalue if and only if

$$u_1(R, \lambda)\psi'_+(R, \lambda) - u'_1(R, \lambda)\psi_+(R, \lambda) = 0$$

which holds if and only if $g_R(\lambda) = 0$.

We proceed on to the proof of inclusion for the essential spectrum of $T$, which consists in proving that there exists eigenvalues of $T_R$ accumulating to $\mu + i\gamma$ as $R \to \infty$. We can only achieve this with the additional assumption that $\mu + i\gamma$ does not lie in a region of the complex plane in which either $\beta_u(R, \cdot)$ or $\beta_l(R, \cdot)$ become small as $R \to \infty$. We now define a subset of the complex plane capturing such regions.

**Definition 2.31.** Define a subset $S_\tau \subset \mathbb{C}$ by

$$S_\tau = \left\{ \lambda \in i\gamma + V_\mu \cap \mathbb{R} : \liminf_{R \to \infty} |\beta_j(R, \lambda)| = 0, \ j = u \text{ or } l \right\}. \quad (2.65)$$

The strategy of the proof is to first introduce an approximation $g_\infty^R(\lambda)$ to $g_R(\lambda)$ which is valid for $\lambda$ near $\mu + i\gamma$. It is then shown that there exists zeros $\lambda^\infty_R$ of $g_\infty^R$ converging to $\mu + i\gamma$ as $R \to \infty$. A family of simple closed contours $\ell^R$ surrounding $\lambda^\infty_R$ are constructed such that $\text{dist}(\ell^R, \mu + i\gamma) \to 0$ as $R \to \infty$. We estimate $|g_\infty^R|$ from below and $|g_R - g_\infty^R|$ from above on $\ell^R$ to conclude, using Rouché’s Theorem, that there exists a zero $\lambda^R$ of $g_R$ inside $\ell^R$ for all large enough $R$. Such $(\lambda^R)$ would be eigenvalues of $T_R$ and would converge to $\mu + i\gamma$ as $R \to \infty$, giving the result.

**Lemma 2.32.** The function $\kappa_u - \kappa_l$ has an analytic inverse $(\kappa_u - \kappa_l)^{-1} : B_\delta(w_0) \to \mathbb{C}$ for some small enough $\delta > 0$, where $w_0 := (\kappa_u - \kappa_l)(\mu)$.
2.4 Inclusion for the essential spectrum

Proof. Let \( h = \kappa_u - \kappa_l - w_0 \). Let \( \varepsilon > 0 \) be small enough so that \( |h| > 0 \) on \( \partial B_\varepsilon(\mu) \). Assumption 2.27 (i) implies that any \( z \in \partial B_\varepsilon(\mu) \) satisfies

\[
\arg \left( \frac{h}{|h|}(z) \right) = \arg(h(z)) \in \begin{cases} 
(0, \pi) & \text{if } z \in \mathbb{C}_+ \cap V_\mu \\
\{0, \pi\} & \text{if } z \in \mathbb{R} \cap V_\mu \\
(\pi, 2\pi) & \text{if } z \in \mathbb{C}_- \cap V_\mu 
\end{cases}.
\]

(2.66)

Note that \( \arg \) is set so that \( \arg(z) = 0 \) if \( z \in \mathbb{R}_+ \). The topological degree (i.e. the winding number) of the map \( h/|h| : \partial B_\varepsilon(0) \to \partial B_1(0) \) is equal to the number of zeros for \( h \) in \( B_\varepsilon(0) \), counted with multiplicity [81, pg. 110]. (2.66) implies that the topological degree of \( h/|h| \) can only be 1, hence \( \mu \) is a simple zero of \( \kappa_u - \kappa_l \). The lemma now follows from the inverse function theorem.

\[\square\]

Theorem 2.33. Assume that \( \mu \in \text{int}(\sigma_e(T_0)) \) is such that \( \mu + i\gamma \notin S_\varepsilon \). There exists eigenvalues \( \lambda_R \) of \( T_R \) (\( R \) large enough) and a constant \( C_0 = C_0(T_0, \gamma, \mu) > 0 \) such that

\[|\lambda_R - (\mu + i\gamma)| \leq \frac{C_0}{R}\]

for all large enough \( R \).

Proof. Let \( C > 0 \) be an arbitrary constant independent of \( R \) and \( \theta \).

Define approximation \( g_R^\infty \) to \( g_R \) by

\[g_R^\infty(\lambda) = \beta_u R e^{i\kappa_u(\lambda - i\gamma)R} - \beta_l R e^{i\kappa_l(\lambda - i\gamma)R}\]

where \( \beta_{u,R} := \beta_u(R, \mu + i\gamma) \) and \( \beta_{l,R} := -\beta_l(R, \mu + i\gamma) \). By the definition of \( S_\varepsilon \), the \( L^\infty \) estimates (2.26) of Assumption 2.15 (ii) and the \( L^\infty \) estimates (2.58) of Assumption 2.27 (ii), there exists \( C_1, C_2 > 0 \) independent of \( R \) such that \( \beta_{u,R} \) and \( \beta_{l,R} \) satisfy

\[C_1 \leq |\beta_{j,R}| \leq C_2 \quad (j = u \text{ or } l)\]

(2.67)

for all large enough \( R \). \( g_R^\infty(\lambda) = 0 \) holds if and only if

\[(\kappa_u - \kappa_l)(\lambda - i\gamma) = -\frac{i}{R} \left( \log \left( \frac{\beta_{l,R}}{\beta_{u,R}} \right) + 2\pi i n \right) =: \tilde{\kappa}(n)\]

(2.68)

for some \( n \in \mathbb{Z} \).
Let \( w_0 := (\kappa_u - \kappa_l)(\mu) \) and \( n(R) := \lfloor Rw_0/(2\pi) \rfloor \). Note that \( n(R) \) is well-defined since \( \mu \in \mathbb{R} \) and \( \text{Im} w_0 = 0 \) by Assumption 2.27. Using (2.67),

\[
|\tilde{\kappa}(n(R)) - w_0| \leq \frac{1}{R} \log \left( \frac{\beta_l(R)}{\beta_u(R)} \right) + \frac{2\pi n(R)}{R} - w_0 \leq \frac{C}{R}
\]
for large enough \( R \). By Lemma 2.32, there exists an analytic inverse \( (\kappa_u - \kappa_l)^{-1} : B_{2\delta}(w_0) \to \mathbb{C} \) for some small enough \( \delta > 0 \). Let \( R_0 > 0 \) be large enough such that \( \tilde{\kappa}(n(R)) \) lies in \( B_\delta(w_0) \) for all \( R \geq R_0 \). Define

\[
\lambda_R^\infty = (\kappa_u - \kappa_l)^{-1}(\tilde{\kappa}(n(R))) + i\gamma \quad (R \geq R_0).
\]

Then \( s_R^\infty(\lambda_R^\infty) = 0 \) and, by the analyticity of \( (\kappa_u - \kappa_l)^{-1} \) as well as (2.69),

\[
|\lambda_R^\infty - (\mu + i\gamma)| \leq C|\tilde{\kappa}(n(R)) - w_0| \leq \frac{C}{R}
\]
for large enough \( R \). For \( R \geq R_0 \), define family \( \ell_R = \{\ell_R(\theta) : \theta \in [0, 2\pi)\} \) of simple closed contours around \( \lambda_R^\infty \) by

\[
\ell_R(\theta) = (\kappa_u - \kappa_l)^{-1}(\tilde{\kappa}(n(R))) + \frac{\delta}{R} e^{i\theta} + i\gamma.
\]

By the analyticity of \( (\kappa_u - \kappa_l)^{-1} \) and estimate (2.71), we have that

\[
|\ell_R(\theta) - (\mu + i\gamma)| \leq |\ell_R(\theta) - \lambda_R^\infty| + |\lambda_R^\infty - (\mu + i\gamma)| \leq \frac{C}{R}
\]
for large enough \( R \).

By a direct computation, we have

\[
e^{i\kappa_u(\ell_R(\theta) - i\gamma)R} = \frac{\beta_l(R)}{\beta_u(R)} e^{i\delta e^{i\theta} e^{i\kappa_l(\ell_R(\theta) - i\gamma)R}}.
\]

By Assumption 2.27 (ii), \( \beta_u(R, \cdot) \) and \( \beta_l(R, \cdot) \) are analytic and bounded in \( R \) uniformly in a small enough neighbourhood of \( \mu + i\gamma \), so, using the Cauchy integral formula as in (2.44) and using (2.73),

\[
|\beta_j(R, \ell_R(\theta)) - \beta_j(R, \mu + i\gamma)| \leq C|\ell_R(\theta) - (\mu + i\gamma)| \leq \frac{C}{R} \quad (j = u \text{ or } l)
\]
for large enough $R$. Using (2.67), (2.74) and (2.75),

$$
|g_R(\ell_R(\theta)) - g_R^\infty(\ell_R(\theta))| \\
\leq \left( |\beta_u(R, \ell_R(\theta)) - \beta_{u,R}| + |\beta_l(R, \ell_R(\theta)) + \beta_{l,R}| \right) e^{-\text{Im} \kappa(\ell_R(\theta) - i\gamma)R} \\
\leq \frac{C}{R} e^{-\text{Im} \kappa(\ell_R(\theta) - i\gamma)R}
$$

for large enough $R$. Similarly,

$$
|g_R^\infty(\ell_R(\theta))| = |\beta_{l,R}| e^{i\delta e^{i\theta} - 1} e^{-\text{Im} \kappa(\ell_R(\theta) - i\gamma)R} \geq Ce^{-\text{Im} \kappa(\ell_R(\theta) - i\gamma)R}.
$$

For each large enough $R$, Rouché’s condition

$$
|g_R(\ell_R(\theta)) - g_R^\infty(\ell_R(\theta))| < |g_R^\infty(\ell_R(\theta))|
$$

is satisfied so there exists a zero $\lambda_R$ of $g_R$ in the interior of $\ell_R$ such that

$$
|\lambda_R - (\mu + i\gamma)| \leq |\lambda_R - \lambda_R^\infty| + |\lambda_R^\infty - (\mu + i\gamma)| \leq \frac{C_0}{R}
$$

for some $C_0 > 0$ independent of $R$. \qed

We finish this section with a characterisation of the set $S_\varepsilon$ in the case that $T_0$ is a Schrödinger operator with an $L^1$ or an eventually real periodic potential.

**Definition 2.34.** Define function $\Lambda_u : [0, \infty) \times (i\gamma + V_\mu) \to \mathbb{C}$ by

$$
\Lambda_u(R, \lambda) = \tilde{\varphi}_u(R, \lambda - i\gamma) \tilde{\psi}^d_+(R, \lambda) - \tilde{\phi}_u^d(R, \lambda - i\gamma) \tilde{\psi}_+(R, \lambda)
$$

(2.76)

and define function $\Lambda_l : [0, \infty) \times (i\gamma + V_\mu) \to \mathbb{C}$ by

$$
\Lambda_l(R, \lambda) = \tilde{\psi}_+(R, \lambda) \tilde{\phi}_l^d(R, \lambda - i\gamma) - \tilde{\psi}^d_+(R, \lambda) \tilde{\varphi}_l(R, \lambda - i\gamma).
$$

(2.77)

By the definition of $\beta_u$ and $\beta_l$ in Theorem 2.30,

$$
\beta_u(R, \lambda) = BC[\varphi_l(\cdot, \lambda - i\gamma)] \Lambda_u(R, \lambda) \text{ and } \beta_l(R, \lambda) = BC[\varphi_u(\cdot, \lambda - i\gamma)] \Lambda_l(R, \lambda)
$$

hence we have the following characterisation of $S_\varepsilon$:

**Corollary 2.35.** $S_\varepsilon$ can be decomposed as

$$
S_\varepsilon = (i\gamma + S_{\varepsilon,0}) \cup S_{\varepsilon,u} \cup S_{\varepsilon,l}
$$

(2.78)
where
\[ S_{r,0} := \{ z \in V_\mu \cap \mathbb{R} : BC[\varphi_u(\cdot, z)] = 0 \ or \ BC[\varphi_l(\cdot, z)] = 0 \} \] (2.79)

and
\[ S_{r,j} := \left\{ \lambda \in i\gamma + V_\mu \cap \mathbb{R} : \liminf_{R \to \infty} |\Lambda_j(R, \lambda)| = 0 \right\} \quad (j = u \ or \ l). \] (2.80)

**Definition 2.36.** We refer to the zeros \( z \) of \( BC[\varphi_u(\cdot, z)] \) and \( BC[\varphi_l(\cdot, z)] \) as the resonances of \( T_0 \). Therefore, the elements of \( S_{r,0} \) are precisely the resonances of \( T_0 \) in \( V_\mu \cap \mathbb{R} \). We refer to resonances that are located in the essential spectrum of \( T_0 \) as embedded resonances.

**Remark 2.37.** Since \( \varphi_u \) and \( \varphi_l \) are analytic continuations of the solution \( \psi_+ \) from Assumption 2.15, the functions \( z \mapsto BC[\varphi_u(\cdot, z)] \) and \( z \mapsto BC[\varphi_l(\cdot, z)] \) are analytic continuations of the function \( z \mapsto BC[\psi_+(\cdot, z)] \). The zeros \( z \) of \( BC[\psi_+(\cdot, z)] \) are eigenvalues of \( T_0 \), therefore, by our convention, eigenvalues are also resonances.

**Example 2.38** (Schrödinger operators with \( L^1 \) potentials, continued). Consider again the case \( p = r = 1 \) with \( q \in L^1(0, \infty) \) satisfying the necessary conditions ensuring that Assumption 2.27 holds, as discussed in Example 2.28. In this case, since the functions \( E_\pm(R, \lambda) \) and \( E_\pm^d(R, \lambda) \) tend to zero as \( R \to \infty \) for any \( \lambda, \Lambda_u \) and \( \Lambda_l \) satisfy
\[ |\Lambda_j(R, \lambda)| \to |\sqrt{\lambda - i\gamma} - \sqrt{\lambda}| \quad \text{as} \quad R \to \infty \quad (j = u \ or \ l) \]
for all \( \lambda \in i\gamma + V_\mu \), where the square-root is understood to have been analytically continued from \( \mathbb{C}_+ \) (\( \mathbb{C}_- \)) into \( V_\mu \) in the case \( j = u \) (\( j = l \)) respectively. Since \( \sqrt{\lambda - i\gamma} \neq \sqrt{\lambda} \) for all \( \lambda \in i\gamma + V_\mu \), regardless of which branch-cut for the square-root is chosen, we have
\[ S_{r,u} = S_{r,l} = \emptyset. \]

Consequently,
\[ S_r = i\gamma + S_{r,0}, \]
that is, \( \mu + i\gamma \in S_r \) if and only if \( \mu \) is a resonance of \( T_0 \).

**Example 2.39** (Eventually periodic Schrödinger operators, continued). Consider the case \( p = r = 1 \) with \( q \) real-valued and \( q|_{[X, \infty)} \) \( a \)-periodic for some \( X \geq 0 \) and \( a > 0 \). Assume that \( \eta \in [0, \pi) \), so that \( T_0 \) is equipped with a real mixed boundary condition at 0. Note that \( T_0 \) is self-adjoint in this case. \( q \) is eventually real periodic so by Example 2.29, Assumption 2.27 is satisfied. The sets \( S_{r,u} \) and \( S_{r,l} \) satisfy
\[ S_{r,u} = S_{r,l} = \emptyset. \] (2.81)
Consequently,

\[ S_\tau = i\gamma + S_{\tau,0}, \]

that is, \( \mu + i\gamma \in S_\tau \) if and only if \( \mu \) is a resonance of \( T_0 \).

**Proof of (2.81).** We will only prove (2.81) for \( j = u \), the proof for \( j = l \) is similar.

Assume for contradiction that \( S_{\tau,u} \) is non-empty and let \( \lambda \in S_{\tau,u} \). By unique continuation, expressions analogous to (2.38) and (2.39) hold for \( \tilde{\phi}_u \) and \( \tilde{\phi}_u^d \). By these expressions, there exists a sequence \( (x_{0,n}) \subset [X, X + a) \) such that \( \Lambda_u(x_{0,n}, \lambda) \to 0 \) as \( n \to \infty \). Let \( x_0 \) be any accumulation point of \( (x_{0,n}) \). Then, since \( \Lambda_u(\cdot, \lambda) \) is absolutely continuous, it holds that \( \Lambda_u(x_0, \lambda) = 0 \), so,

\[ \varphi_u(x_0, \lambda - i\gamma) \psi^+_u(x_0, \lambda) - \varphi_u'(x_0, \lambda - i\gamma) \psi^+(x_0, \lambda) = 0. \]  

(2.82)

Noting that the solutions \( \phi_1(\cdot, \lambda - i\gamma) \) and \( \phi_2(\cdot, \lambda - i\gamma) \) defined by (2.30) are real since \( \lambda - i\gamma \in \mathbb{R} \) and that the analytic continuations \( \rho_u(\rho_l) \) for \( \rho_+ \) from \( \mathbb{C}_+(\mathbb{C}_-) \) respectively satisfy \( \rho_u(\lambda - i\gamma) = \rho_l(\lambda - i\gamma) \), the expression analogous to (2.35) for the Floquet solution \( \phi_u \) implies that

\[ \varphi_u(x, z) = -\phi_2(X + a, z)\phi_1(x, z) + (\phi_1(X + a, z) - \rho_u(z))\phi_2(x, z) = \varphi_l(x, z) \]

where \( z := \lambda - i\gamma \). Consequently we have,

\[ \varphi_l(x_0, \lambda - i\gamma) \overline{\psi^+_l}(x_0, \lambda) - \varphi_l'(x_0, \lambda - i\gamma) \overline{\psi^+_l}(x_0, \lambda) = 0. \]  

(2.83)

By (2.82) and (2.83), there exists \( C_{1,u}, C_{2,u}, C_{1,l}, C_{2,l} \in \mathbb{C}\setminus\{0\} \) independent of \( x \) such that the functions

\[ u_u(x, \lambda) := \begin{cases} 
C_{1,u}\varphi_u(x, \lambda - i\gamma) & \text{if } x \in [0, x_0) \\
C_{2,u}\psi^+_u(x, \lambda) & \text{if } x \in [x_0, \infty) 
\end{cases} \]

and

\[ u_l(x, \lambda) := \begin{cases} 
C_{1,l}\varphi_l(x, \lambda - i\gamma) & \text{if } x \in [0, x_0) \\
C_{2,l}\psi^+_l(x, \lambda) & \text{if } x \in [x_0, \infty) 
\end{cases} \]

are absolutely continuous and solve the Schrödinger equation \( \tilde{T}_{x_0}u = \lambda u \). Note that \( \overline{\psi^+_l} \) solves the Schrödinger equation \( \tilde{T}_{x_0}u = \lambda u \) on \( [x_0, \infty) \) because \( q \) is real-valued. By orthogonality, there exists \( (a_u, a_l) \in \mathbb{C}^2\setminus\{(0,0)\} \) such that

\[ BC[a_uu_u(\cdot, \lambda) + a_lu_l(\cdot, \lambda)] = a_uC_{1,u}BC[\varphi_u(\cdot, \lambda - i\gamma)] + a_lC_{1,l}BC[\varphi_l(\cdot, \lambda - i\gamma)] = 0 \]
This implies that $\lambda$ is an eigenvalue of $T_{\delta_0}$ with corresponding eigenfunction $u := a_0 u_a + a_1 u_1$. By a standard integration by parts,

$$\text{Im}(\lambda) = \gamma \int_0^{\infty} |u|^2 < \gamma$$

which is the desired contradiction.

2.5 Numerical examples

In this section, we illustrate the results from Sections 2.3 and 2.4 with numerical examples.

Example 2.40. Consider perturbed operators of the form

$$T_R = -\frac{d^2}{dx^2} + i\chi_{[0,R]}(x) \quad (R \in \mathbb{R}_+) \quad (2.84)$$
endowed with Dirichlet boundary conditions at 0. This corresponds to the case $p = r = 1$, $q = 0$, $\eta = 0$ and $\gamma = 1$ in Sections 2.3 and 2.4.

By an explicit computation, $\lambda \in \mathbb{C}\setminus[0, \infty)$ is an eigenvalue of $T_R$ if and only if

$$f_R(\lambda) = i\sqrt{\lambda}\sin(R\sqrt{\lambda - i}) - \sqrt{\lambda - i}\cos(R\sqrt{\lambda - i}) = 0. \quad (2.85)$$

Note that our convention is that the branch cut of the square-root is along $[0, \infty)$. By suitably analytically continuing the square root function in (2.85), any $\lambda$ in the lower right quadrant of the complex plane is a resonance of $T_R$ if and only if $f_R(\lambda) = 0$.

To numerically compute the zeros of $f_R$, hence the eigenvalues and resonances of $T_R$, in a fixed bounded region, we use a Python implementation of an algorithm utilising the argument principle [52]. The results are illustrated in Figure 2.2.

For small enough $R > 0$, $T_R$ has no eigenvalues [68]. As $R$ increased, we observe resonances in the lower half plane emerging out of $\sigma_e(T_R) = [0, \infty)$, to become eigenvalues in the numerical range $\Gamma_\gamma := \sigma_e(T_0) + i[0, \gamma] = [0, \infty) + i[0, \gamma]$ of $T_0$ accumulating to $\sigma_e(T) = i\gamma + [0, \infty)$, as expected by Theorem 2.33.

Example 2.41. Consider perturbed operator of the form

$$T_R = T_0 + i\chi_{[0,R]}(x) = -\frac{d^2}{dx^2} + i\chi_{[0,R]}(x) + i\chi_{[0,R]}(x) \quad (R \in \mathbb{R}_+) \quad (2.86)$$

endowed with Dirichlet boundary conditions at 0. This corresponds to the case $p = r = 1$, $\eta = 0$, $q = i\chi_{[0,R_0]}$ for some $R_0 > 0$ and $\gamma = 1$ in Sections 2.3 and 2.4.

By an explicit computation, $\lambda \in \mathbb{C}\setminus[0, \infty)$ is an eigenvalue of $T_R$ if and only if

$$f_R(\lambda) = i\sqrt{\lambda - i} \left[ e^{-2i\sqrt{\lambda - i}(R - R_0)} - \frac{\sqrt{\lambda - i} - \sqrt{\lambda}}{\sqrt{\lambda - i} + \sqrt{\lambda}} \sin(\sqrt{\lambda - 2iR_0}) \right]$$

$$- \sqrt{\lambda - 2i} \left[ e^{-2i\sqrt{\lambda - i}(R - R_0)} + \frac{\sqrt{\lambda - i} - \sqrt{\lambda}}{\sqrt{\lambda - i} + \sqrt{\lambda}} \cos(\sqrt{\lambda - 2iR_0}) \right] = 0 \quad (2.87)$$

As before, by suitably analytically continuing the square root function in (2.87), any $\lambda$ in the lower right quadrant of the complex plane is a resonance of $T_R$ if and only if $f_R(\lambda) = 0$.

A numerical computation of the zeros of $f_R$, hence the eigenvalues and resonances of $T_R$ is shown in Figure 2.3. We observe that there are eigenvalues of $T_R$ converging
rapidly to the eigenvalues of $T$ and that eigenvalues of $T_R$ accumulate to $\sigma_e(T) = i\gamma + [0, \infty)$, as expected by Theorems 2.23 and 2.33.

Recall that Example 2.39 guarantees that the rate of convergence of eigenvalues of $T_R$ to $\mu \in \text{int}(\sigma_e(T)) = i\gamma + (0, \infty)$ is $O(1/R)$, unless $\mu$ is a resonance of $T$. The limit operator $T$ for our choice of parameters has a resonance embedded in $\sigma_e(T)$. We seem to observe a distinction between the way the eigenvalues of $T_R$ accumulate to the resonance compared to other points in the interior of $\sigma_e(T)$. It seems reasonable to conjecture that the rate of convergence to embedded resonances is indeed slower that $O(1/R)$.

Example 2.42. Consider perturbed operators of the form

$$T_R = T_0 + \frac{i}{4} \chi_{[0,R]}(x) = -\frac{d^2}{dx^2} + \sin(x) + \frac{i}{4} \chi_{[0,R]}(x) \quad (R \in \mathbb{R}_+ \quad (2.88)$$

endowed with a Dirichlet boundary condition at 0. This corresponds to the case $p = r = 1$, $\eta = 0$, $q(x) = \sin(x)$ and $\gamma = \frac{1}{4}$ in Section 2.3 and 2.4. The essential spectrum of $T_0$ has a band gap structure - the first spectral band, which we denote by $B$, is approximately $[-0.3785, -0.3477]$ [104, Example 15].

To numerically compute the eigenvalues of $T_R$, we first perform a domain truncation onto an interval $[0,X]$, imposing a Dirichlet boundary condition at $X$. Applying a finite difference method with step-size $h$, we obtain a finite matrix $T_{R,X,h}$. For fixed $R$, the eigenvalues of $T_{R,X,h}$ accumulate to every point in $\sigma(T_R)$ as $X \to \infty$ and $h \to 0$. Moreover, any point of accumulation that does not lie in $\sigma(T_R)$ must lie on the real-line (see [37] and [104]).

For a fixed small value of $h$, a fixed large value of $X - R$, the eigenvalues of $T_{R,X,h}$ for increasing $R$ are plotted in Figure 2.4. We first observe an accumulation of eigenvalues of $T_{R,X,h}$ to the interval $B$ in $\mathbb{R}$. These eigenvalues of $T_{R,X,h}$ are due to the domain truncation method approximating $\sigma_e(T_R)$ and should not be interpreted as approximations of the eigenvalues of $T_R$. All other points in the plots are approximations of the eigenvalues of $T_R$.

In Figure 2.4, we observe that as $R$ increases, eigenvalues of $T_R$ emerge out of the spectral band $B$ and tend to the shifted spectral band $i\gamma + B$, which is a subset of $\sigma_e(T)$. For large $R$, we observe an accumulation of eigenvalues to $i\gamma + B$. The eigenvalues of $T_R$ accumulating to $i\gamma + B$ seem to be contained in $B + i(0, \gamma)$. If this is indeed the case then by Bolzano-Weiestrass we expect that there is spectral pollution in $B + i(0, \gamma)$. 
2.5 Numerical examples

Figure 2.3 Plot of eigenvalues and resonances of the operators $T_R$ and $T = T_0 + i\gamma$ defined by (2.86), with $R_0 = 4.7$. Note that the definition of resonances for $T_R$ falls under Definition 2.36 since the dissipative barrier $i\gamma\chi_{[0,R]}$ is compactly supported. Furthermore, a complex number $\lambda$ is a resonances of $T_0 + i\gamma$ if $\lambda - i\gamma$ is a resonance of $T_0$. 
Figure 2.4 Plot of eigenvalues of the domain truncation and finite difference approximation $T_{R,X,h}$ of the operator $T_R$ defined by (2.88). $h = 0.05$ and $X - R = 300$ are fixed. The region $B + i\mathbb{R}$ is shaded in light blue.
3.1 Introduction

There has recently been a surge of interest concerning bounds for the magnitude of eigenvalues and the number of eigenvalues of Schrödinger operators with complex potentials. In this chapter, we consider Schrödinger operators of the form

$$H_R = -\frac{d^2}{dx^2} + q + i\gamma\chi_{[0,R]}$$

on $L^2(0,\infty)$ ($R > 0$),

endowed with a Dirichlet boundary condition at 0, where $\gamma > 0$ and the background potential $q \in L^1(0,\infty)$ (which may be complex-valued) are regarded as fixed parameters. Perturbations of the form $i\gamma\chi_{[0,R]}$ are referred to as dissipative barriers and arise in spectral approximation, where they can be utilised as part of numerical schemes for the computation of eigenvalues [104, 130, 4, 102, 103, 133]. Our aim is to prove estimates for the magnitude and number of eigenvalues of $H_R$ for large $R$.

3.1.1 Existing bounds for the magnitude and number of eigenvalues

Let us first discuss some relevant existing results concerning the eigenvalues of (non-self-adjoint) Schrödinger operators and apply them to operators of the form $H_R$.

In [1], Abramov, Aslanyan and Davies investigated bounds for complex eigenvalues of Schrödinger operators, in particular obtaining a bound [1, Theorem 4] for
Table 3.1 A summary of the large $R$ asymptotic estimates for the eigenvalues of $H_R$ implied by our results compared to estimates obtained by applying various results in the literature.

Schrödinger operator on $L^2(\mathbb{R})$ with a potential $V \in L^1(\mathbb{R}) \cap L^2(\mathbb{R})$. Such magnitude bounds were later generalised to include more general potentials, higher dimensions and more general geometries [43, 50, 62, 65, 71, 80, 92, 94, 122]. The work most relevant to this chapter was undertaken by Frank, Laptev and Seiringer [69], where they show that any eigenvalue $\lambda$ of a Schrödinger operator $-d^2/dx^2 + V$ on $L^2(\mathbb{R}^+)$, endowed with a Dirichlet boundary condition at 0, satisfies

$$\sqrt{|\lambda|} \leq \|V\|_{L^1}.$$  \hspace{1cm} (3.2)

Note that the right hand side of the bound presented in [69] depends on $\arg \lambda$ and is sharper than (3.2). An application of this result to operators of the form $H_R$ gives an estimate $\sqrt{|\lambda_R|} = O(R)$ as $R \to \infty$ for any eigenvalue $\lambda_R$ of $H_R$.

Proving bounds for the number of eigenvalues of a Schrödinger operator is often regarded as a more difficult problem. A sufficient condition for the potential $V$ to ensure that the number of eigenvalues of a Schrödinger operator on $L^2(\mathbb{R}^+)$ is finite is the Naimark condition [108]:

$$\exists a > 0: \int_0^\infty e^{at}|V(t)|dt < \infty.$$  \hspace{1cm} (3.3)

There exist other such sufficient conditions and it is known that the number of eigenvalues may not be finite for certain potentials decaying only sub-exponentially [112, 113].
Quantitative bounds for the number of eigenvalues of a Schrödinger operator on $L^2(\mathbb{R}^d)$ were proved by Stepin in [131, 132] for dimensions $d = 1, 3$. Bounds for arbitrary odd dimensions were later proved by Frank, Laptev and Safronov in [68], which give better large $R$ estimates when applied to operators $H_R$ of the form (3.1). [68, Theorem 1.1] states that the number of eigenvalues $N$ (counting algebraic multiplicity) of a Schrödinger operator $-d^2/dx^2 + V$ on $L^2(\mathbb{R}_+)$ endowed with a Dirichlet boundary condition at 0 satisfies

$$N \leq \frac{1}{\varepsilon^2} \left( \int_0^\infty e^{\varepsilon t} |V(t)| \, dt \right)^2,$$

(3.4)

for any $\varepsilon > 0$. With the assumption that the background potential $q$ satisfies the Naimark condition, applying this inequality to $H_R$ gives an estimate $N(H_R) = O(R^4)$ as $R \to \infty$ for the number of eigenvalues (counting algebraic multiplicities) $N(H_R)$ of $H_R$.

Additionally, Korotyaev has proved in [90, Theorem 1.6] a bound specific to Schrödinger operators with compactly supported potentials: the number of eigenvalues $N$ of a Schrödinger operator $-d^2/dx^2 + V$ on $L^2(\mathbb{R}_+)$ endowed with a Dirichlet boundary condition at 0, with $V \in L^1(\mathbb{R}_+)$ and $\text{supp} V \subseteq [0, Q]$, satisfies

$$N \leq C_1 + C_2 Q \|V\|_{L^1},$$

(3.5)

where $C_1, C_2 > 0$ are some numerical constants. With the assumption that the background potential $q$ is compactly supported, applying this inequality to $H_R$ gives an estimate $N(H_R) = O(R^2)$ as $R \to \infty$. We mention also other estimates for numbers of eigenvalues in [23, 86, 127].

### 3.1.2 Summary of results

Table 3.1 summarises our results for the large $R$ behaviour of the eigenvalues of $H_R$ and compares them to the application of the existing results to operators of the form $H_R$.

Let $H_R^{(0)}$ denote the operator $H_R$ for the case $q \equiv 0$. The semi-infinite strip

$$\Gamma_\gamma := (0, \infty) + i(0, \gamma) \subset \mathbb{C}$$

(3.6)

plays an important role throughout the chapter and has the property that its closure $\overline{\Gamma}_\gamma$ is equal to the numerical range of the operator $H_R^{(0)}$ for any $R > 0$. An open ball in $\mathbb{C}$ of radius $r > 0$ about a point $z_0 \in \mathbb{C}$ is denoted by $B_r(z_0)$. Note that in this chapter we make no attempt to optimise numerical constants.

Our first result gives a uniform in $R$ enclosure for the eigenvalues of $H_R$:
(A) (Theorem 3.4 (a)) There exists $X = X(q, \gamma) > 0$ such that, for any $R > 0$, the eigenvalues of $H_R$ lie in $B_X(0) \cup \Gamma_\gamma$.

In particular, the imaginary and negative real parts of the eigenvalues are bounded independently of $R$.

Our next result is a bound for the magnitude of eigenvalues of $H_R$ for sufficiently large $R$. The bound gives the estimate $\sqrt{|\lambda_R|} = O(R/\log R)$ as $R \to \infty$ for any eigenvalue $\lambda_R$ of $H_R$ providing a logarithmic improvement to the application of the result [69] of Frank, Laptev and Seiringer to this system.

(B) (Theorem 3.4 (b)) There exists $R_0 = R_0(q, \gamma) > 0$ such that for every $R \geq R_0$, any eigenvalue $\lambda$ of $H_R$ in $\Gamma_\gamma$ satisfies

$$\sqrt{|\lambda - i\gamma|} \leq \frac{5\gamma R}{\log R}. \quad (3.7)$$

(B) is obtained by considering an analytic function whose zeros are the eigenvalues of $H_R$ and applying large-$|\lambda|$ Levinson asymptotics.

The fact that large eigenvalues of $H_R$ for large $R$ must be contained in the numerical range of $H_R^{(0)}$ and the right hand side of inequality (3.7) is independent of $q$ indicates that the effect of the background potential $q$ on the large eigenvalues is dominated by effect of the dissipative barrier $i\gamma \chi_{[0,R]}$ for large $R$.

Our first estimate for the number of eigenvalues $N(H_R)$ for $H_R$ is for the case that the background potential $q$ is compactly supported. It gives the estimate $N(H_R) = O(R^2/\log R)$ as $R \to \infty$, which offers a logarithmic improvement to the application of the result [90, Theorem 1.6] of Korotyaev to this system.

(C) (Theorem 3.10) If $q$ is compactly supported then there exists $R_0 = R_0(q, \gamma) > 0$ such that for every $R \geq R_0$,

$$N(H_R) \leq \frac{11}{\log 2} \frac{\gamma R^2}{\log R}.$$

The proof consists in an application of Jensen’s formula.

The case in which the background potential $q$ merely satisfies the Naimark condition requires more sophisticated techniques compared to the compactly supported case. Our result gives the estimate $N(H_R) = O(R^3/(\log R)^2)$ as $R \to \infty$, providing a more significant improvement to the application of the result [68, Theorem 1.1] of Frank, Laptev and Safronov to this system, which gives $N(H_R) = O(R^4)$. The reasons for the more significant improvement are discussed below.
(D) (Theorem 3.14) If there exists \( a > 0 \) such that
\[
\int_0^\infty e^{4at}|q(t)|\,dt < \infty.
\]
then there exists \( R_0 = R_0(q, \gamma) > 0 \) such that for every \( R \geq R_0 \),
\[
N(H_R) \leq C \frac{\sqrt{X} + a}{a^2} \frac{\gamma^2 R^3}{(\log R)^2}
\]
where \( X = X(q, \gamma) > 0 \) is the constant appearing in (A) and \( C = 88788 \).

The proof of (D) involves first obtaining a bound which counts the number of
zeros in a strip for an arbitrary analytic function in the upper half plane (Proposition
3.12). This bound can be applied to the estimation of \( N(H_R) \) thanks to the uniform
in \( R \) enclosure (A), which implies that the square-roots of the eigenvalues of \( H_R \) are
contained in a strip, uniformly in \( R \). Without the uniform enclosure, we would have
to use the magnitude bound (B) in place of the uniform enclosure with which the
best we could obtain is inequality (3.8) with \( \sqrt{X} \) replaced by \( O(R/\log R) \), giving the
large \( R \) estimate \( N(H_R) = O(R^4/(\log R)^3) \). This indicates that the more significant
improvement in (D) is due to the combination of a bound for the quantity \( \text{Im}\sqrt{\lambda} \) of
the eigenvalues \( \lambda \) with the bound Proposition 3.12 for analytic functions.

Operators of the form \( H_R^{(0)} \), corresponding to the special case \( q = 0 \), have been
studied by Bögli and Štampach in [22], by Golinskii in [77] and by Cuenin in [44]. As
discussed in Chapter 1, lower bounds for \( H_R^{(0)} \) show that Theorem 3.4 (b) and Theorem
3.10 provide optimal large \( R \) estimates.

3.1.3 Notations and conventions
Throughout the chapter, \( C > 0 \) denotes a constant, whose dependencies are generally
indicated, that may change from line to line. \( \psi'(x, \lambda) \) will denote \( \frac{d}{\lambda} \psi(x, \lambda) \) throughout.
The branch cut of \( \sqrt{\cdot} \) is made along \( \sigma_e(H_R) = [0, \infty) \), so that \( \text{Im}\sqrt{z} \geq 0 \) for all \( z \in \mathbb{C} \).
\( N(H_R) \) shall denote the number of eigenvalues of \( H_R \), counting algebraic multiplicities
(as above). Finally, note that \( f_R \) will always denote an analytic function but will be
redefined in each section.

3.2 Magnitude bound
Since \( q \in L^1(0, \infty) \), we can employ Levinson’s asymptotic theorem which states that
the solution space of the Schrödinger equation \(-u'' + qu = \lambda u \) on \([0, \infty)\) is spanned by
solutions \( \psi_+ \) and \( \psi_- \), which admit the decomposition \([107, \text{Appendix II, Theorems 1 and 3}]\) \([60, \text{Theorem 1.3.1}]\):

\[
\psi_\pm(x, \lambda) = e^{\pm i \sqrt{\lambda} x} (1 + E_\pm(x, \lambda)) \\
\psi'_\pm(x, \lambda) = \pm i \sqrt{\lambda} e^{\pm i \sqrt{\lambda} x} (1 + E^d_\pm(x, \lambda))
\]  \(x \in [0, \infty), \lambda \in \mathbb{C} \setminus \{0\}\). \(3.9\)

Here, \( E_\pm \) and \( E^d_\pm \) are some functions such that,

\[
|E_\pm(x, \lambda)| + |E^d_\pm(x, \lambda)| \to 0 \quad \text{as} \quad x \to \infty
\]  \(3.10\)

for all \( \lambda \in \mathbb{C} \setminus \{0\} \), and

\[
|E_\pm(x, \lambda)| + |E^d_\pm(x, \lambda)| \leq \frac{C(q)}{\sqrt{|\lambda|}}
\]  \(3.11\)

for all \( x \in [0, \infty) \) and \( \lambda \in \mathbb{C} \) with \( |\lambda| \geq 1 \).

While the error \( E_+(x, \lambda) \) tends to 0 as \( x \to \infty \) uniformly for \( \lambda \in \mathbb{C} \setminus B_{\delta}(0), \delta > 0 \), the error \( E_- \) does not have this property. For this reason, we will need to utilise large-\( |\lambda| \) asymptotics of \( \psi_\pm \) in this section.

**Lemma 3.1.** \( \lambda \in \mathbb{C} \setminus [0, \infty) \) with \( \lambda \neq i\gamma \) is an eigenvalue of \( H_R \) if and only if \( f_R(\lambda) = 0 \), where

\[
f_R(\lambda) := \psi_-(-0, \lambda - i\gamma) \left( \sqrt{\lambda} - \sqrt{\lambda - i\gamma + \mathcal{E}_1(R, \lambda)} \right) e^{i \sqrt{\lambda - i\gamma}} \\
- \psi_+(0, \lambda - i\gamma) \left( \sqrt{\lambda} + \sqrt{\lambda - i\gamma + \mathcal{E}_2(R, \lambda)} \right) e^{-i \sqrt{\lambda - i\gamma}}.
\]

Here, \( \mathcal{E}_1, \mathcal{E}_2 \) are defined, for any \( R > 0 \) and \( \lambda \in \mathbb{C} \setminus \{0, i\gamma\} \), by

\[
\mathcal{E}_1(R, \lambda) = \sqrt{\lambda} \left( E_+(R, \lambda - i\gamma) + E^d_+(R, \lambda) + E_+(R, \lambda - i\gamma) E^d_+(R, \lambda) \right) \\
- \sqrt{\lambda - i\gamma} \left( E^d_+(R, \lambda - i\gamma) + E_+(R, \lambda) + E^d_+(R, \lambda - i\gamma) E_+(R, \lambda) \right), \quad (3.12)
\]

\[
\mathcal{E}_2(R, \lambda) = \sqrt{\lambda} \left( E^d_+(R, \lambda) + E_-(R, \lambda - i\gamma) + E^d_+(R, \lambda) E_-(R, \lambda - i\gamma) \right) \\
+ \sqrt{\lambda - i\gamma} \left( E_+(R, \lambda) + E^d_+(R, \lambda - i\gamma) + E_+(R, \lambda) E^d_-(R, \lambda - i\gamma) \right), \quad (3.13)
\]

and, for some \( \mathcal{C}_1 = \mathcal{C}_1(q, \gamma) > 0 \), satisfy

\[
|\mathcal{E}_1(R, \lambda)| + |\mathcal{E}_2(R, \lambda)| \leq \mathcal{C}_1 \quad (3.14)
\]
for all $R > 0$ and all $\lambda \in \mathbb{C}$ with $|\lambda| \geq 1 + \gamma$. Furthermore, $f_R$, $\mathcal{E}_1(R, \cdot)$ and $\mathcal{E}_2(R, \cdot)$ are analytic on $\mathbb{C} \setminus ([0, \infty) \cup (i\gamma + [0, \infty)))$.

Proof. Let $\lambda \in \mathbb{C} \setminus [0, \infty)$ with $\lambda \neq i\gamma$. $\lambda$ is an eigenvalue of $H_R$ if and only if there exists a solution to the boundary value problem

$$-\psi'' + (q + i\gamma \chi_{[0,R]}) \psi = \lambda \psi$$

on $[0, \infty)$, $\psi(0) = 0, \psi \in L^2(0, \infty)$. (3.15)

Any solution to (3.15) on $[0,R]$ must be of the form $C_1 \psi_1(\cdot, \lambda)$, where

$$\psi_1(x, \lambda) := \psi_-(0, \lambda - i\gamma) \psi_+(x, \lambda - i\gamma) - \psi_+(0, \lambda - i\gamma) \psi_-(x, \lambda - i\gamma)$$

(3.16)

and $C_1 \in \mathbb{C}$ is independent of $x$. Any solution to the boundary value problem (3.15) on $[R, \infty)$ must be of the form $C_2 \psi_+(x, \lambda)$, where $C_2 \in \mathbb{C}$ is independent of $x$. Hence $\lambda$ is an eigenvalue if and only if there exists $C_1, C_2 \in \mathbb{C} \setminus \{0\}$ independent of $x$ such that the function

$$x \mapsto \begin{cases} C_1 \psi_1(x, \lambda) & \text{if } x \in [0,R) \\ C_2 \psi_+(x, \lambda) & \text{if } x \in [R, \infty) \end{cases}$$

is continuously differentiable which holds if and only if

$$i f_R(\lambda) e^{i\sqrt{\lambda}R} \equiv \psi_1(R, \lambda) \psi'_+(R, \lambda) - \psi'_1(R, \lambda) \psi_+(R, \lambda) = 0.$$  \hspace{1cm} (3.17)

The required expression for $f_R$ holds by a direct computation, using expressions (3.9) for $\psi_\pm$.

For $\lambda \in \mathbb{C}$ with $|\lambda| \geq 1 + \gamma$ we have $|\lambda| \geq 1$ and $|\lambda - i\gamma| \geq 1$. Therefore, estimates (3.11) apply to all the terms in (3.12) and (3.13) involving $E_\pm$ or $E^d_\pm$. The $O(1/\sqrt{|\lambda|})$ decay of the terms involving $E_\pm$ or $E^d_\pm$ as $|\lambda| \to \infty$ cancels the growth of the square roots, hence estimate (3.14) holds. Finally, $f_R$, $\mathcal{E}_1(R, \cdot)$ and $\mathcal{E}_2(R, \cdot)$ are analytic on $\mathbb{C} \setminus ([0, \infty) \cup (i\gamma + [0, \infty)))$ because $\sqrt{\lambda}$, $E_\pm(R, \cdot)$ and $E^d_\pm(R, \cdot)$ are analytic on $\mathbb{C} \setminus [0, \infty)$. 

In the special case $q \equiv 0$, $f_R$ is denoted by $f^{(0)}_R$ and we have that:

$\lambda \in \mathbb{C} \setminus [0, \infty)$ is an eigenvalue of $H^{(0)}_R$ if and only if $f^{(0)}_R(\lambda) = 0$.

The terms $E_\pm$ and $E^d_\pm$ in Levinson’s asymptotic theorem are simply zero for this case, so

$$f^{(0)}_R(\lambda) = (\sqrt{\lambda} - \sqrt{\lambda - i\gamma}) e^{i\sqrt{\lambda} - i\gamma R} - (\sqrt{\lambda} + \sqrt{\lambda - i\gamma}) e^{-i\sqrt{\lambda} - i\gamma R}.$$  \hspace{1cm} (3.18)
Lemma 3.2. There exists a constant $C_2 = C_2(q, \gamma) > 0$ such that

$$|f_R(\lambda) - f_R^{(0)}(\lambda)| \leq C_2 e^{\text{Im}\sqrt{\lambda - i\gamma R}}$$

for all $R > 0$ and all $\lambda \in \mathbb{C}$ with $|\lambda| \geq 1 + \gamma$.

Proof. By a direct computation, using Lemma 3.1 and the fact that

$$\psi_\pm(0, \lambda - i\gamma) = 1 + E_\pm(0, \lambda - i\gamma),$$

we have

$$(f_R(\lambda) - f_R^{(0)}(\lambda)) e^{\sqrt{\lambda - i\gamma R}} = E_-(0, \lambda - i\gamma) \left[ \sqrt{\lambda} - \sqrt{\lambda - i\gamma} \right] e^{2i\sqrt{\lambda - i\gamma R}}$$

$$- E_+(0, \lambda - i\gamma) \left[ \sqrt{\lambda} + \sqrt{\lambda - i\gamma} \right]$$

$$+ (1 + E_-(0, \lambda - i\gamma)) \delta_1(R, \lambda) e^{2i\sqrt{\lambda - i\gamma R}}$$

$$- (1 + E_+(0, \lambda - i\gamma)) \delta_2(R, \lambda).$$

Each term on the right hand side of (3.19) is bounded uniformly for all $R > 0$ and all $\lambda \in \mathbb{C}$ with $|\lambda| \geq 1 + \gamma$; this follows using the boundedness for $\delta_1$ and $\delta_2$ proved in Lemma 3.1 as well as the large-$|\lambda|$ asymptotics of $E_\pm(0, \lambda - i\gamma)$ in (3.11). In particular, inequality (3.11) implies that $E_\pm(0, \lambda - i\gamma) = O(1/|\lambda|)$ as $|\lambda| \to \infty$, balancing the growth of the factors $\sqrt{\lambda} \pm \sqrt{\lambda - i\gamma}$ in the first two terms of (3.19). $\square$

Recall that $\Gamma_\gamma$ is an open strip defined by equation (3.6). We shall need the following elementary inequalities:

Lemma 3.3. (a) If $\lambda \in \Gamma_\gamma \cup [0, \infty)$ then

$$|\sqrt{\lambda} + \sqrt{\lambda - i\gamma}| \leq \frac{\gamma}{\sqrt{|\lambda - i\gamma|}} \quad \text{and} \quad |\sqrt{\lambda} - \sqrt{\lambda - i\gamma}| \geq \sqrt{|\lambda - i\gamma|}.$$ 

(b) If $\lambda \in \mathbb{C}\setminus(\Gamma_\gamma \cup [0, \infty))$ then

$$|\sqrt{\lambda} + \sqrt{\lambda - i\gamma}| \geq |\lambda| \quad \text{and} \quad |\sqrt{\lambda} - \sqrt{\lambda - i\gamma}| \leq \frac{\gamma}{\sqrt{|\lambda|}}.$$ 

(c) If $\lambda \in \Gamma_\gamma$ then

$$\text{Im}\sqrt{\lambda - i\gamma} \leq \frac{1}{\sqrt{2}} \frac{\gamma}{\sqrt{|\lambda - i\gamma|}}.$$ 

Proof. (a) If $\lambda \in \Gamma_\gamma \cup [0, \infty)$ then

$$\text{sgnRe}\sqrt{\lambda - i\gamma} = -\text{sgnRe}\sqrt{\lambda}, \quad |\text{Re}\sqrt{\lambda - i\gamma}| \geq \text{Im}\sqrt{\lambda - i\gamma} \quad \text{and} \quad |\text{Re}\sqrt{\lambda}| \geq \text{Im}\sqrt{\lambda},$$
so
\[
|\sqrt{\lambda} - \sqrt{\lambda - i\gamma}|^2 = (\text{Re}\sqrt{\lambda})^2 + (\text{Re}\sqrt{\lambda - i\gamma})^2 + (\text{Im}\sqrt{\lambda})^2 + (\text{Im}\sqrt{\lambda - i\gamma})^2 - 2\text{Re}\sqrt{\lambda}\text{Re}\sqrt{\lambda - i\gamma} - 2\text{Im}\sqrt{\lambda}\text{Im}\sqrt{\lambda - i\gamma} \geq |\lambda - i\gamma|.
\] (3.20)

The inequality for \(\sqrt{\lambda} + \sqrt{\lambda - i\gamma}\) follows from the identity
\[
\sqrt{\lambda} + \sqrt{\lambda - i\gamma} = i\gamma \sqrt{\lambda - \sqrt{\lambda - i\gamma}}.
\] (3.21)

(b) If \(\lambda \in i\gamma + \mathbb{C}_+ \cup [0, \infty)\) or \(\lambda \in \mathbb{C}_-\) then, similarly to (3.20),
\[
\text{sgn}\text{Re}\sqrt{\lambda} = \text{sgn}\text{Re}\sqrt{\lambda - i\gamma} \Rightarrow |\sqrt{\lambda} + \sqrt{\lambda - i\gamma}|^2 \geq |\lambda|.
\]

If \(\lambda \in (-\infty, 0] + i[0, \gamma]\) then \(|\text{Re}\sqrt{\lambda}| \leq \text{Im}\sqrt{\lambda}\) and \(|\text{Re}\sqrt{\lambda - i\gamma}| \leq \text{Im}\sqrt{\lambda - i\gamma}\) so
\[
|\sqrt{\lambda} + \sqrt{\lambda - i\gamma}|^2 \geq |\lambda - i\gamma| + |\lambda| \geq |\lambda|,
\]
hence the inequality for \(\sqrt{\lambda} + \sqrt{\lambda - i\gamma}\) holds. The inequality for \(\sqrt{\lambda} - \sqrt{\lambda - i\gamma}\) follows from (3.21).

(c) Let \(\lambda \in \Gamma_\gamma\) and let \(z = \lambda - i\gamma\). Then \(|\text{Im}z| \leq \gamma\) so
\[
2(\text{Im}\sqrt{z})^2 = |z| - \text{Re}z = \frac{(\text{Im}z)^2}{|z| + \text{Re}z} \leq \frac{\gamma^2}{|z|}.
\]

Using the function \(f_R\) for the eigenvalues of \(H_R\), combined with the large-\(|\lambda|\) asymptotics of \(\psi_{\pm}\), we can estimate the location of the eigenvalues of \(H_R\):

**Theorem 3.4.** (a) There exists \(X = X(q, \gamma) > 0\) such that, for any \(R > 0\), the eigenvalues of \(H_R\) lie in \(B_X(0) \cup \Gamma_\gamma\).

(b) There exists \(R_0 = R_0(q, \gamma) > 0\) such that for every \(R \geq R_0\), any eigenvalue \(\lambda\) of \(H_R\) in \(\Gamma_\gamma\) satisfies
\[
|\sqrt{\lambda} - i\gamma| \leq \frac{5\gamma R}{\log R}.
\] (3.22)

**Proof.** (a) Let \(R > 0\). \(H_R\) has no eigenvalues in \([0, \infty)\) (indeed, this follows from the Levinson asymptotic formulas (3.9)) so it suffices to show that any zero of \(f_R\) in \(\mathbb{C} \setminus (\Gamma_\gamma \cup [0, \infty))\) must lie in an open ball in the complex plane, whose radius is
independent of $R$. Let $\lambda \in \mathbb{C} \setminus (\Gamma_\gamma \cup [0, \infty))$ be such that $|\lambda| \geq X$, where $X = X(q, \gamma) > 0$ is a large enough constant to be further specified. Let $X > 0$ be large enough so that $|\lambda| \geq 1 + \gamma$. By the expression for $f_R$ in Lemma 3.1,

$$
|f_R(\lambda)e^{i\sqrt{\lambda - i\gamma}R}| \geq \left| \psi_+(0, \lambda - i\gamma)(\sqrt{\lambda} + \sqrt{\lambda - i\gamma + \mathcal{E}_2(R, \lambda)}) - \psi_-(0, \lambda - i\gamma)(\sqrt{\lambda} - \sqrt{\lambda - i\gamma + \mathcal{E}_1(R, \lambda)}) \right| e^{-2\text{Im}\sqrt{\lambda - i\gamma}R}
$$

(3.23)

By the boundedness of $\mathcal{E}_1$ and $\mathcal{E}_2$ (Lemma 3.1 and estimates (3.11)), as well an inequality in Lemma 3.3 (b), there exists $C_1 = C_1(q, \gamma) > 0$ such that

$$
\left| \psi_-(0, \lambda - i\gamma)(\sqrt{\lambda} - \sqrt{\lambda - i\gamma + \mathcal{E}_1(R, \lambda)}) \right| e^{-2\text{Im}\sqrt{\lambda - i\gamma}R} \leq C_1.
$$

(3.24)

Let $\delta > 0$. Recall that $|\mathcal{E}_2(R, \lambda)| \leq \mathcal{C}_1$, where $\mathcal{C}_1 > 0$ is the constant appearing in Lemma 3.1. Let $X > 0$ be large enough such that $|\psi_+(0, \lambda - i\gamma)| \geq \frac{1}{2}$ and

$$
\sqrt{\lambda} \geq 2(C_1 + \delta) + \mathcal{C}_1.
$$

Then, using Lemma 3.3 (b),

$$
\left| \psi_+(0, \lambda - i\gamma)(\sqrt{\lambda} + \sqrt{\lambda - i\gamma + \mathcal{E}_2(R, \lambda)}) \right| \geq \frac{1}{2} \sqrt{|\lambda| - \mathcal{C}_1} \geq C_1 + \delta.
$$

(3.25)

Combining (3.23), (3.24) and (3.25), we have

$$
|f_R(\lambda)| \geq \delta > 0.
$$

Consequently, $\lambda$ is not an eigenvalue of $H_R$ proving that there are no eigenvalues of $H_R$ in $\mathbb{C} \setminus \Gamma_\gamma$ with magnitude greater than $X$.

(b) Let $R \geq R_0$, where $R_0 = R_0(q, \gamma) > 0$ is a large enough constant to be further specified. Let $\lambda \in \Gamma_\gamma$ be such that

$$
\sqrt{|\lambda - i\gamma|} \log |\lambda - i\gamma| \geq 8\gamma R.
$$

(3.26)

We aim to prove that $\lambda$ is not an eigenvalue of $H_R$.

Using the expression (3.18) for $f_R^{(0)}$,

$$
\frac{|f_R^{(0)}(\lambda)|}{|\lambda - i\gamma|^{1/4}} e^{-1\text{Im}\sqrt{\lambda - i\gamma}R} \geq \left| \frac{\sqrt{\lambda} - \sqrt{\lambda - i\gamma}}{|\lambda - i\gamma|^{1/4}} e^{-2\text{Im}\sqrt{\lambda - i\gamma}R} - \frac{\sqrt{\lambda} + \sqrt{\lambda - i\gamma}}{|\lambda - i\gamma|^{1/4}} \right|
$$
Using the inequality (3.26) and Lemma 3.3 (c), \( \lambda \) satisfies
\[
e^{-2\text{Im}\sqrt{\lambda-i\gamma R}} \geq e^{-\sqrt{2}\gamma R/\sqrt{|\lambda-i\gamma|}} \geq e^{-\frac{\sqrt{2}}{8}\log|\lambda-i\gamma|} = \frac{1}{|\lambda-i\gamma|^{\sqrt{2}/8}}.
\] (3.27)

Ensure \( R_0 > 0 \) is large enough so that \(|\lambda-i\gamma|^{1/4} \geq 2|\lambda-i\gamma|^{\sqrt{2}/8} \). Then, using Lemma 3.3 (a),
\[
\frac{|\sqrt{\lambda} - \sqrt{\lambda-i\gamma}|}{|\lambda-i\gamma|^{1/4}} \geq |\lambda-i\gamma|^{1/4} \geq 2|\lambda-i\gamma|^{\sqrt{2}/8}.
\] (3.28)

Ensure also that \( R_0 > 0 \) is large enough so that \(|\lambda-i\gamma| \geq 2\gamma^{A/3} \). Combining (3.28) with (3.27) and using Lemma 3.3 (a) again,
\[
\frac{|\sqrt{\lambda} - \sqrt{\lambda-i\gamma}|}{|\lambda-i\gamma|^{1/4}} e^{-2\text{Im}\sqrt{\lambda-i\gamma R}} \geq 2 \geq 1 + \frac{\sqrt{\lambda} + \sqrt{\lambda-i\gamma}}{|\lambda-i\gamma|^{1/4}}.
\]
and hence
\[
|f_R^{(0)}(\lambda)| \geq |\lambda-i\gamma|^{1/4} e^{\text{Im}\sqrt{\lambda-i\gamma R}}.
\] (3.29)

In particular, \( f_R^{(0)}(\lambda) \neq 0 \).

Recall that \( C_2 = C_2(q, \gamma) > 0 \) denotes the constant appearing in Lemma 3.2. Ensure that \( R_0 > 0 \) is large enough so that \(|\lambda| \geq 1 + \gamma \) and \(|\lambda-i\gamma|^{1/4} \geq 2C_2 \). By (3.29) and Lemma 3.2,
\[
|f_R(\lambda) - f_R^{(0)}(\lambda)| \leq C_2 e^{\text{Im}\sqrt{\lambda-i\gamma R}} \leq \frac{1}{2} |\lambda-i\gamma|^{1/4} e^{\text{Im}\sqrt{\lambda-i\gamma R}} \leq \frac{1}{2} |f_R^{(0)}(\lambda)|
\]
therefore \( f_R(\lambda) \neq 0 \) and, consequently, \( \lambda \) is not an eigenvalue of \( H_R \). This proves that any eigenvalue of \( H_R \) must satisfy
\[
\sqrt{|\lambda-i\gamma|} \log \sqrt{|\lambda-i\gamma|} \leq 4\gamma R.
\] (3.30)

Let \( W \) denote the Lambert-W-function (also known as the product log function). \( W \) satisfies
\[
W(x) = \log \left( \frac{x}{W(x)} \right) \quad \text{and} \quad y \log y = x \iff y = \frac{x}{W(x)} \quad (x > 0, y > 0).
\]
Hence (3.30) can be written as
\[
\sqrt{|\lambda-i\gamma|} \leq \frac{4\gamma R}{W(4\gamma R)} = \frac{4\gamma R}{\log(4\gamma R) - \log(W(4\gamma R))}.
\]
from which (3.22) follows (note that it is well known that \( W(x) = o(x) \) as \( x \to \infty \).)

**Remark 3.5.** The constant \( X = X(q, \gamma) > 0 \) in Theorem 3.4 (a) satisfies

\[
X = O(\|q\|_{L^1}^3) \quad \text{as} \quad \|q\|_{L^1} \to \infty.
\]

This can be seen by noting that \( E_\pm(R, \lambda), E^d_\pm(R, \lambda) = O(\|q\|_{L^1}) \) (see [60, Chapter 1.4]), \( C_1 = O(\|q\|_{L^1}^2) \) and \( C_1 = O(\|q\|_{L^1}^3) \).

### 3.3 Number of eigenvalues

In this section, we estimate the number of eigenvalues for \( H_R \), for which we necessarily need to add additional assumptions on the background potential \( q \).

#### 3.3.1 Preliminaries

Let \( \psi_\pm \) denote the solutions (3.9) for the Schrödinger equation and

\[
\varphi(x, z) := \psi_+(x, z^2) \quad (x \in [0, \infty), z \in \mathbb{C}_+).
\]

\( \varphi \) is commonly referred to as the *Jost solution*. For each \( R > 0 \), define function \( f_R: \mathbb{C}_+ \to \mathbb{C} \) by

\[
if_R(z)e^{izR} = \theta(R, z)\varphi'(R, z) - \theta'(R, z)\varphi(R, z) \quad (z \in \mathbb{C}_+).
\]

where, for any \( z \in \mathbb{C} \), \( \theta(\cdot, z) \) is defined as the solution to the initial value problem

\[
-\theta'' + q\theta = (z^2 - i\gamma)\theta, \quad \theta(0) = 0, \theta'(0) = 1. \tag{3.31}
\]

By the same arguments as in Lemma 3.1, we have the following.

**Lemma 3.6.** \( f_R \) is analytic on \( \mathbb{C}_+ \) and any \( z \in \mathbb{C}_+ \) satisfies

\[
f_R(z) = 0 \quad \iff \quad z^2 \text{ is an eigenvalue of } H_R. \tag{3.32}
\]

\( \varphi \) can be decomposed in a similar way to \( \psi_\pm \),

\[
\varphi(x, z) = e^{izx}(1 + E(x, z)) \quad (x \in [0, \infty), z \in \mathbb{C}_+) \tag{3.33}
\]

\[
\varphi'(x, z) = ixe^{izx}(1 + E^d(x, z))
\]
for some functions $E$ and $E^d$ whose properties will be later specified, for the different assumptions on the background potential $q$ that we consider. We shall need the following facts concerning $f_R$ and $\theta$. Note that in Lemma 3.1, $\delta_1$ and $\delta_2$ are defined in a different way than in Lemma 3.1.

**Lemma 3.7.** Suppose that, for each $R > 0$, $\varphi(R, \cdot)$ and $\varphi'(R, \cdot)$ admits an analytic continuation from $\mathbb{C}_+$ into some open $U \subset \mathbb{C}$. Then, $f_R$ admits analytic continuation into $U$. Furthermore, for each $R > 0$ and $z \in U \setminus \{\pm \sqrt{i\gamma}\}$,

$$ f_R(z)u(z) = \psi_+(0, z^2 - i\gamma)(z - \sqrt{z^2 - i\gamma + \delta_1(R, z)})e^{i\sqrt{z^2 - i\gamma}R} \qquad \text{(3.34)} $$

where

$$ u(z) := \psi_-(0, z^2 - i\gamma)\psi'(0, z^2 - i\gamma) - \psi_+(0, z^2 - i\gamma)\psi'_-(0, z^2 - i\gamma), \qquad \text{(3.35)} $$

$$ \delta_1(R, z) := z\left(E_+(R, z^2 - i\gamma) + E^d(R, z) + E_+(R, z^2 - i\gamma)E_+(R, z)\right) \quad - \sqrt{z^2 - i\gamma}\left(E_+(R, z^2 - i\gamma) + E(R, z) + E_+(R, z^2 - i\gamma)E(R, z)\right) \qquad \text{(3.36)} $$

and

$$ \delta_2(R, z) := z\left(E^d(R, z) + E_-(R, z^2 - i\gamma) + E^d(R, z)E_-(R, z^2 - i\gamma)\right) \quad + \sqrt{z^2 - i\gamma}\left(E(R, z) + E^d(R, z^2 - i\gamma) + E(R, z)E^d(R, z^2 - i\gamma)\right) \qquad \text{(3.37)} $$

**Proof.** Analytic continuation holds by the fact that $\theta(R, \cdot)$ is entire [135, Lemma 5.7] for each $R > 0$. If $z \neq \pm \sqrt{i\gamma}$ then the functions $\psi_\pm(\cdot, z^2 - i\gamma)$ span the solution space of the Schrödinger equation $-\psi'' + q\psi = (z^2 - i\gamma)\psi$ so

$$ \theta(R, z) = \frac{\psi_+(0, z^2 - i\gamma)\psi'-(R, z^2 - i\gamma) - \psi_+(0, z^2 - i\gamma)\psi_-(R, z^2 - i\gamma)}{\psi_+(0, z^2 - i\gamma)\psi'_-(0, z^2 - i\gamma) - \psi_+(0, z^2 - i\gamma)\psi'_-(0, z^2 - i\gamma)} = \frac{\psi_1(R, z^2)}{u(z)} $$

where $\psi_1$ denotes the function defined by (3.16) in Lemma 3.1. The lemma follows by a direct computation, similar to one in Lemma 3.1. \qed
Lemma 3.8. For any $x \in [0, \infty)$ and $z \in \mathbb{C} \setminus \{\pm i\gamma\}$, the solution $\theta$ to the initial value problem (3.31) satisfies the inequality

$$|\theta(x, z)| + |\theta'(x, z)| \leq (1 + x)e^{\text{Im}\sqrt{z^2 - i\gamma}|x|} \exp\left(\int_0^x (1 + t)|q(t)|\,dt\right).$$

Proof. Let $\mu = \mu(z) := \sqrt{z^2 - i\gamma}$. $\theta$ and $\theta'$ satisfy the integral equations

$$\theta(x, z) = \frac{\sin(\mu x)}{\mu} + \int_0^x \frac{\sin(\mu(x - t))}{\mu} q(t)\theta(t, z)\,dt$$

and

$$\theta'(x, z) = \cos(\mu x) + \int_0^x \cos(\mu(x - t))q(t)\theta(t, z)\,dt,$$

hence satisfy the integral inequality

$$|\theta(x, z)| + |\theta'(x, z)| \leq (1 + x)e^{\text{Im}\mu|x|} \left[1 + \int_0^x e^{-\text{Im}\mu|x|} |q(t)|\left(|\theta(t, z)| + |\theta'(t, z)|\right)\,dt\right],$$

where we used the fact that $|\sin(\mu x)| |\mu|^{-1} \leq xe^{\text{Im}\mu|x|}$ and $|\cos(\mu x)| \leq e^{\text{Im}\mu|x|}$. The result follows from an application of Grönwall’s Lemma. \qed

3.3.2 Compactly supported potentials

Assumption 3.9. $q$ is compactly supported, that is, there exists $Q > 0$ such that

$$\text{supp } q \subset [0, Q].$$

If Assumption 3.9 holds and then the Jost solution $\varphi$ satisfies

$$\varphi(R, z) = e^{izR} \quad (R > Q, z \in \mathbb{C}_+)$$

hence, for each $x \in [0, \infty)$, $\varphi(x, \cdot)$ can be analytically continued to $\mathbb{C}$. Consequently, for $R > Q$, $f_R$ can be analytically continued to $\mathbb{C}$ and can be written as

$$f_R(z) = z\theta(R, z) + i\theta'(R, z) \quad (z \in \mathbb{C}).$$

Theorem 3.10. Suppose that Assumption 3.9 holds. Then there exists $R_0 = R_0(q, \gamma) > 0$ such that for every $R \geq R_0$,

$$N(H_R) \leq \frac{11}{\log 2} \frac{\gamma R^2}{\log R}.$$
3.3 Number of eigenvalues

**Proof.** Let \( z_0 \in \mathbb{C}_+ \) be such that

\[
\psi_+(0, z_0^2 - i\gamma) \neq 0, \quad \text{Im} \sqrt{z_0^2 - i\gamma} \geq 1 \quad \text{and} \quad \sqrt{|z_0^2 - i\gamma|} \leq 2. \tag{3.41}
\]

In fact, by choosing \( z_0 \) to be the minimiser of some suitable total order on \( \mathbb{C} \) in the set of points that maximise \( z \mapsto \psi_+(0, z^2 - i\gamma) \) while satisfying the latter two inequalities of (3.41), \( z_0 \) can be determined uniquely by \( q \) and \( \gamma \); \( z_0 = z_0(q, \gamma) \). Define \( r = r(R) > 0 \) by

\[
\frac{r}{2} = \gamma^{1/2} + |z_0| + \frac{5\gamma R}{\log R}. \tag{3.42}
\]

By the triangle inequality,

\[
|z - z_0| \leq |z| + |z_0| \leq \sqrt{|z^2 - i\gamma| + \gamma} + |z_0| \leq \sqrt{|z^2 - i\gamma| + \gamma^{1/2} + |z_0|} \tag{3.43}
\]

so,

\[
S_R := \left\{ z \in \mathbb{C}_+ : \sqrt{|z^2 - i\gamma|} \leq \frac{5\gamma R}{\log R} \right\} \subseteq B_{r/2}(z_0). \tag{3.44}
\]

Let \( R > Q > 0 \) be large enough so that estimate (3.22) of Theorem 3.4 (b) holds. Since the zeros of \( f_R \) in \( \mathbb{C}_+ \) have a bijective correspondence with the eigenvalues of \( H_R \), the set \( S_R \) contains all the zeros of \( f_R \) in \( \mathbb{C}_+ \) and hence the number of eigenvalues of \( H_R \) is bounded by the number of zeros for \( f_R \) in the ball \( B_{r/2}(z_0) \),

\[
N(H_R) \leq |f_R^{-1}\{0\} \cap B_{r/2}(z_0)|. \tag{3.45}
\]

Since \( f_R \) is entire, Jensen’s formula gives us

\[
|f_R^{-1}\{0\} \cap B_{r/2}(z_0)| \leq \frac{1}{\log 2} \log \left| \frac{1}{f_R(z_0)} \right| \sup_{|z-z_0|=r} |f_R(z)|. \tag{3.46}
\]

Since \( R > Q \), the terms \( \mathcal{E}_1(R, z) \) and \( \mathcal{E}_2(R, z) \), defined by (3.36) and (3.37) respectively, vanish. Hence, by Lemma 3.7 and the fact that \( \text{Im} \sqrt{z_0^2 - i\gamma} \geq 1 \),

\[
|f_R(z_0)u(z_0)| \geq |\psi_+(0, z_0^2 - i\gamma)(z_0 + \sqrt{z_0^2 - i\gamma})|e^R
- |\psi_-(0, z_0^2 - i\gamma)(z_0 - \sqrt{z_0^2 - i\gamma})|e^{-R}.
\]
Note that $\text{Im} \sqrt{z_0^2 - i\gamma} \geq 1$ implies that $z_0 \neq \pm \sqrt{i\gamma}$ so Lemma 3.7 is indeed applicable here. Then, since $\psi_+(0, z_0^2 - i\gamma) \neq 0$, $\sqrt{|z_0^2 - i\gamma|} \leq 2$ and $z_0 = z_0(q, \gamma)$,

$$|f_R(z_0)| \geq C(q, \gamma) \quad (3.47)$$

for large enough $R$.

By expression (3.39) for $f_R$ and the estimates in Lemma 3.8 for $\theta$ and $\theta'$, for all $z \in \partial B_r(z_0)$,

$$|f_R(z)| \leq C(q)(1 + R)(1 + |z|) e^{i\sqrt{z^2 - i\gamma} R}. \quad (3.48)$$

Furthermore, by the triangle inequality and expression (3.42) for $r$, for all $z \in \partial B_r(z_0)$,

$$\sqrt{|z^2 - i\gamma|} \leq |z - z_0| + |z_0| + \gamma^{1/2} = 3\gamma^{1/2} + 3|z_0| + \frac{10\gamma R}{\log R}. \quad (3.49)$$

Noting that for $z \in \partial B_r(z_0)$, the factor $(1 + |z|)$ in (3.48) is $o(R)$, combining (3.45) - (3.49) gives us

$$N(H_R) \leq \frac{1}{\log 2} \left( \log o(R^2) + \left(3\gamma^{1/2} + 3|z_0|\right) R + \frac{10\gamma R^2}{\log R} \right)$$

as $R \to \infty$. Estimate (3.40) follows. \hfill \Box

### 3.3.3 Exponentially decaying potentials

**Assumption 3.11 (Naimark Condition).** There exists $a > 0$ such that

$$\int_0^\infty e^{4at} |q(t)| dt < \infty.$$

If Assumption 3.11 is satisfied then for each $x > 0$ the functions $\varphi(x, \cdot)$ and $\varphi'(x, \cdot)$ admit analytic continuations from $\mathbb{C}_+$ into $\{\text{Im} z > -2a\}$. For each $x > 0$, the functions $E$ and $E^d$ appearing in the decomposition (3.33) of the Jost solution $\varphi$ satisfy

$$|E(x, z)| + |E^d(x, z)| \leq C(q) \quad \text{if} \quad \text{Im} z \geq -a \quad (3.50)$$

and

$$|E(x, z)| + |E^d(x, z)| \leq \frac{C(q)}{|z|} \quad \text{if} \quad \text{Im} z \geq -a \text{ and } |z| \geq 1. \quad (3.51)$$

See [108, Theorem 2.6.1] and [131, Lemma 1] for proofs of the above claims.

The next proposition allows us to utilise the uniform enclosure of Theorem 3.4 (a) in the estimation of the number of eigenvalues of $H_R$. 
Proposition 3.12. Suppose that $f$ is an analytic function defined on an open neighbourhood of the closed semi-disc $D_r := \overline{B_r(0)} \cap \mathbb{C}_+$ for some $r > 0$. Let $\alpha$ and $\beta$ be any numbers in the interval $(0, 1)$ satisfying

$$\beta \left( \frac{1 - \alpha}{\alpha + \beta} \right)^2 > \frac{Y}{\eta} \quad (3.52)$$

and let $N(\alpha r)$ denote the number of zeros of $f$ in the region

$$D_{\alpha r, \eta, Y} := \{ z \in \mathbb{C} : \eta \leq \text{Im}z \leq Y, |z| \leq \alpha r \} \quad (3.53)$$

where $Y, \eta > 0$ are given parameters satisfying $\eta < Y < r$. Then,

$$N(\alpha r) \leq \frac{2}{\log \Lambda(r)} \log \left( \frac{1}{\min\{\beta, 1 - \beta\}} \sup_{z \in \partial D_r} |f(z)| \right) \quad (3.54)$$

where

$$\Lambda(r) := \frac{1 + \frac{4\beta\eta}{(\alpha + \beta)^2} \frac{1}{r}}{1 + \frac{4\eta}{(1 - \alpha)^2} \frac{1}{r}}. \quad (3.55)$$

Remark 3.13. One can always guarantee that condition (3.52) for $\alpha$ and $\beta$ is satisfied by choosing, for instance,

$$\alpha = \beta = \frac{1}{4} \frac{\eta}{2Y + \eta}. \quad (3.56)$$

Figure 3.1 Illustration for the setup of Proposition 3.12.
Proof of Proposition 3.12. Let \( \{z_j\}_{j=1}^{N(\alpha r)} \) denote the set of zeros of \( f \) in the set \( D_{\alpha r, \eta, Y} \) and consider the Blaschke product

\[
b(z) := \prod_j \frac{z - z_j}{z - z_j^*} = \prod_j b_j(z).
\]

Note that higher multiplicity zeros of \( f \) are repeated in the set \( \{z_j\} \) accordingly. Let \( z_0 := i\beta r \). The function \( f(z)b(z) \) is analytic on an open neighbourhood of \( D_r \) so by Cauchy’s formula,

\[
\frac{1}{2\pi i} \oint_{\partial D_r} \frac{f(z)b(z)}{z - z_0} dz = f(z_0)b(z_0). \tag{3.57}
\]

Observing that \( |z - z_0| \geq \min\{\beta, 1 - \beta\}r \) for all \( z \in \partial D_r \), it holds that

\[
\frac{1}{2\pi} \oint_{\partial D_r} \frac{|dz|}{|z - z_0|} \leq \frac{1}{\min\{\beta, 1 - \beta\}},
\]

which can be used to estimate the integral in (3.57) to get

\[
\prod_j \frac{|b_j(z_0)|}{\sup_{z \in \partial D_r} |b_j(z)|} \leq \frac{\sup_{z \in \partial D_r} |f(z)|}{|f(z_0)|} \frac{1}{\min\{\beta, 1 - \beta\}}. \tag{3.58}
\]

By a direct computation, we have

\[
|b_j(z)| = \sqrt{1 + \frac{4\Im z \Im z_j}{|z - z_j|^2}}.
\]

Since

\[
\Im z_0 = \beta r, \quad \Im z_j \geq \eta, \quad |z_0 - z_j| \leq (\alpha + \beta)r,
\]

giving us a lower bound for \( |b_j(z_0)| \), and since for any \( z \in \mathbb{C} \) with \( |z| = r \)

\[
\Im z \leq r, \quad \Im z_j \leq Y, \quad |z - z_j| \geq (1 - \alpha)r,
\]

giving us an upper bound for \( |b_j(z)| \), we have

\[
\frac{|b_j(z_0)|}{|b_j(z)|} \geq \Lambda(r)^{1/2} \tag{3.59}
\]

for any \( z \in \partial D_r \) with \( |z| = r \). Furthermore, if \( z \in \mathbb{R} \) then \( |b_j(z)| = 1 \) so (3.59) in fact holds for every \( z \in \partial D_r \). Combining (3.59) with (3.58) gives us

\[
\Lambda(r)^{N(\alpha r)/2} \leq \frac{1}{\min\{\beta, 1 - \beta\}} \sup_{z \in \partial D_r} \frac{|f(z)|}{|f(z_0)|}. \tag{3.60}
\]
If hypothesis (3.52) for \( \alpha \) and \( \beta \) holds then \( \Lambda(r) > 1 \) so we can take the logarithm of both sides of (3.60) and rearrange to obtain inequality (3.54).

**Theorem 3.14.** Suppose that Assumption 3.11 holds. Then there exists \( R_0 = R_0(q, \gamma) > 0 \) such that for every \( R \geq R_0 \),

\[
N(H_R) \leq C \frac{\sqrt{X} + a}{a^2} \frac{\gamma^2 R^3}{(\log R)^2}
\]  

(3.61)

where \( C = 88788 \) and \( X = X(q, \gamma) > 0 \) is the constant appearing in Theorem 3.4 (a).

**Proof.** Let \( \tilde{f}_R(z) := f_R(z - ia) \) and let \( \alpha, \beta > 0 \) satisfy equation (3.56) of Remark 3.13 with \( \eta = a \) and \( Y = \sqrt{X} + a \) where \( X = X(q, \gamma) \) is the constant appearing in Theorem 3.4. Then hypothesis (3.52) of Proposition 3.12 is satisfied. Note that with this choice of \( \beta \) we have \( \beta < 1/2 \), so,

\[
\min\{\beta, 1 - \beta\} = \beta.
\]  

(3.62)

The zeros of \( \tilde{f}_R \) in \( \{\text{Im} z > a\} \) have a bijective correspondence to eigenvalues of \( H_R \) given by

\[
(z - ia)^2 \in \sigma_d(H_R) \iff \text{Im} z > a \text{ and } \tilde{f}_R(z) = 0.
\]  

(3.63)

Assuming without loss of generality that \( X \geq \gamma \), the square root of any element of \( B_X(0) \cup \Gamma_{\gamma} \) is contained in the strip \( \{0 \leq \text{Im} w \leq \sqrt{X}\} \subset \mathbb{C} \). Then by the uniform enclosure of Theorem 3.4 (a), the zeros of \( \tilde{f}_R \) in \( \{\text{Im} z > a\} \) are contained in the strip \( \{a \leq \text{Im} z \leq \sqrt{X} + a\} \). By the triangle inequality and the magnitude bound of Theorem 3.4 (b), any zero \( z \) of \( \tilde{f}_R \) with \( \text{Im} z > a \) satisfies

\[
|z| \leq \gamma^{1/2} + a + \sqrt{|(z - ia)^2 - i\gamma|} \leq \alpha r
\]  

(3.64)

where \( r = r(R) \) is defined by

\[
\alpha r = \gamma^{1/2} + a + \frac{5\gamma R}{\log R}.
\]  

(3.65)

Hence the zeros of \( \tilde{f}_R \) in \( \{\text{Im} z > a\} \) are contained in \( D_{\alpha r, \eta, \gamma} \).

Applying Proposition 3.12, we get an estimate for the number of eigenvalues of \( H_R \),

\[
N(H_R) = |\tilde{f}_R^{-1}(\{0\}) \cap D_{\alpha r, \eta, \gamma}| \leq \frac{2}{\log \Lambda(r)} \log \left( \frac{1}{\beta} \frac{\sup_{z \in \partial D_{\nu}} |\tilde{f}_R(z)|}{|\tilde{f}_R(i\nu)|} \right),
\]  

(3.66)
where
\[ \Lambda(r) = \frac{1 + C_1/r}{1 + C_2/r} \] (3.67)
for some constants \( C_1 > C_2 > 0 \) depending only on \( X \) and \( a \). The remainder of the proof consists in estimating the right hand side of (3.66).

Let \( z_R := i\beta r(R) - ia \). By Lemma 3.7,
\[
|f_R(z_R)u(z_R)| \geq |\psi_+(0, z_R^2 - i\gamma)(z_R + \sqrt{z_R^2 - i\gamma} + \delta_2(R, z_R))| \\
- |\psi_-(0, z_R^2 - i\gamma)(z_R - \sqrt{z_R^2 - i\gamma} + \delta_1(R, z_R))| 
\] (3.68)
for large enough \( R \). By estimates (3.11) for \( E_\pm \) and \( E^d_\pm \), and the corresponding estimates (3.51) for \( E \) and \( E^d \),
\[
|u(z_R)| + |\psi_-(0, z_R^2 - i\gamma)| + |\delta_1(R, z_R)| + |\delta_2(R, z_R)| \leq C(q, \gamma) 
\] (3.69)
and
\[
|\psi_+(0, z_R^2 - i\gamma)| \geq C(q, \gamma) 
\] (3.70)
for large enough \( R \). By Lemma 3.3,
\[
\lim_{R \to \infty} |z_R + \sqrt{z_R^2 - i\gamma}| = \infty \quad \text{and} \quad \lim_{R \to \infty} |z_R - \sqrt{z_R^2 - i\gamma}| = 0. 
\] (3.71)
Combining (3.68) with (3.69), (3.70) and (3.71) gives us
\[
|\tilde{f}_R(i\beta r)| = |f_R(z_R)| \geq 1 
\] (3.72)
for large enough \( R \).

The factor involving \( \Lambda(r) \) on the right hand side of (3.66) can be estimated using the expression (3.67) for \( \Lambda \) and the inequality \( \log x \geq (x - 1)/(x + 1) \) for \( x \geq 1 \),
\[
\log \Lambda(r) \geq \frac{\Lambda(r) - 1}{\Lambda(r) + 1} = \frac{(C_1 - C_2)/r(R)}{2 + (C_1 + C_2)/r(R)} \geq \frac{C_1 - C_2}{3r(R)} 
\] (3.73)
for large enough \( R \).

The function \( \tilde{f}_R \) is estimated from above using the bound in Lemma 3.8 for \( \theta \) and \( \theta' \) and the uniform bounds (3.50) for \( E(R, \cdot) \) and \( E^d(R, \cdot) \),
\[
|\tilde{f}_R(z)| \leq C(q)(1 + R)(1 + |z|)e^{aR}e^{\sqrt{|z^2 - i\gamma|^2 - i\gamma R}} \quad (z \in \mathbb{C}_+). 
\] (3.74)
Using the expression (3.65) for \( r \), for any \( z \in \partial D_r \) we have
\[
\sqrt{|(z - ia)^2 - i\gamma|} \leqslant \gamma^{1/2} + a + |z| \leqslant O(1) + \frac{5\gamma R}{\alpha \log R} \tag{3.75}
\]
as \( R \to \infty \). Combining (3.66) with (3.72), (3.73), (3.74) and (3.75), noting that \(|z| = o(R)\) for \( z \in \partial D_R \) and \( \beta^{-1} = O(1) \), gives
\[
N(H_R) \leqslant \frac{6}{C_1 - C_2} \left( O(1) + \frac{5\gamma R}{\alpha \log R} \right) \left( O(R) + \frac{5\gamma R^2}{\alpha \log R} \right)
\]
as \( R \to \infty \) and so
\[
N(H_R) \leqslant \frac{151\gamma^2 R^3}{(C_1 - C_2)\alpha^2 (\log R)^2} \tag{3.76}
\]
for large enough \( R \).

Finally, we put the constant into a more illuminating form. By the definition (3.55) of \( \Lambda \) in Proposition 3.12,
\[
C_1 = \frac{\eta}{\alpha} \quad \text{and} \quad C_2 = \frac{4Y}{(1 - \alpha)^2}. \tag{3.77}
\]
Since \( \frac{\eta}{2Y} \leqslant \alpha \leqslant \frac{\eta}{8Y} \), we have
\[
(C_1 - C_2)\alpha^2 = \eta\alpha - \frac{4Y\alpha^2}{(1 - \alpha)^2} \geq \frac{\eta^2}{12Y} - \frac{4Y\alpha^2}{(1 - \eta/8Y)^2} \tag{3.78}
\]
and since \( 0 \leq \eta / Y \leq 1 \), we have
\[
\frac{\alpha^2}{(1 - \eta/8Y)^2} = \frac{\eta^2}{64Y^2 (1 + \eta/2Y)^2 (1 - \eta/8Y)^2} \leq \frac{\eta^2}{49Y^2} \tag{3.79}
\]
Combining (3.78) and (3.79), we have
\[
(C_1 - C_2)\alpha^2 \geq \frac{1}{588} \frac{\eta^2}{Y}. \tag{3.80}
\]
which gives estimate (3.61) when substituted into (3.76), with \( Y = \sqrt{X} + a \) and \( \eta = a \).\( \square \)
Chapter 4

Lieb–Thirring and Jensen sums

Declaration and acknowledgements:
This chapter is joint work with Leonid Golinskii and appears in a similar form in the preprint [79]. We thank S. Bögli and J.-C. Cuenin for helpful discussions and R. Frank for enlightening comments which motivated us to include Proposition 4.23.

4.1 Introduction

There is a vast literature on the spectral theory of self-adjoint Schrödinger operators, motivated by their numerous applications in various areas of mathematical physics. One of the highlights of this theory is the seminal Lieb–Thirring inequality for operators on $L^2(\mathbb{R}^d)$, $d \in \mathbb{N}$, which describes the discrete spectrum of such operators. For the case of real line $d = 1$ it reads [99]

$$
\sum_{\lambda \in \sigma_d(H)} |\lambda|^\mu \leq C(\mu) \int_{-\infty}^{\infty} [q_-(x)]^{\mu+1/2} dx, \quad \mu \geq \frac{1}{2},
$$

where $C(\mu) > 0$ depends only on $\mu$, $H$ denotes a Schrödinger operator on $\mathbb{R}$ with real-valued potential $q$ and $q_-(x) = \max(0, -q(x))$.

By comparison, the non-self-adjoint theory is in its youth. The results obtained in the last two decades have revealed new phenomena and demonstrated crucial differences between SA and NSA theories. Among the problems which have attracted attention, let us mention spectral enclosure results and bounds on the number of complex eigenvalues [1, 50, 92, 65, 71, 68, 20]. Another active area of interest is non-self-adjoint generalisations of Lieb–Thirring inequalities for Schrödinger operators [67, 53, 70, 123, 78, 66, 19], as well as for other types of operators [54, 124, 57, 58, 28]. Still, many questions remain unanswered.
The main object under consideration in the present chapter is a Schrödinger operator
\[ H = H_q := -\frac{d^2}{dx^2} + q \quad \text{on} \quad L^2(\mathbb{R}_+) \] (4.2)
endowed with a Dirichlet boundary condition at 0, where the potential \( q \in L^1(\mathbb{R}_+) \)
may be complex-valued. As is well known, the set of discrete eigenvalues \( \sigma_d(H) \) (i.e.,
eigenvalues of finite algebraic multiplicity in \( \mathbb{C}\setminus\mathbb{R}_+ \)) may be countably infinite and
may accumulate only to \( \mathbb{R}_+ \). Lieb–Thirring-type inequalities give information on the
distribution of the eigenvalues and, in particular, on the rate of accumulation to points in \( \mathbb{R}_+ \).

In this chapter, we study sums of eigenvalues of the form
\[ S_\varepsilon(H) := \sum_{\lambda \in \sigma_d(H)} \frac{\text{dist}(\lambda, \mathbb{R}_+)}{|\lambda|^{(1-\varepsilon)/2}}, \quad \varepsilon \geq 0. \] (4.3)
Here, eigenvalues of higher algebraic multiplicity are repeated in the sums accordingly.
We refer to \( S_\varepsilon(H) \) as the Lieb–Thirring sums. Note that, in the case when \( q \) is real, the
eigenvalues of \( H_q \) are all negative, so \( S_\varepsilon(H_q) \) coincides with the classical Lieb–Thirring
sum in (4.1), with \( \mu = (1 + \varepsilon)/2 \). In this chapter, we use the following shorthand
notation for the \( L^1 \) norm,
\[ \|q\|_1 := \int_0^\infty |q(x)|dx, \quad q \in L^1(\mathbb{R}_+). \] (4.4)
By [69], the spectral enclosure \( |\lambda| \leq \|q\|_1^2 \) holds for every \( \lambda \in \sigma_d(H) \). So, there is a
simple relation between the Lieb–Thirring sums with different \( \varepsilon \)
\[ S_{\varepsilon_2}(H_q) \leq \|q\|_1^{\varepsilon_2-\varepsilon_1} S_{\varepsilon_1}(H_q), \quad 0 \leq \varepsilon_1 < \varepsilon_2. \] (4.5)
We also study the sums
\[ J(H) := \sum_{\lambda \in \sigma_d(H)} \text{Im} \sqrt{\lambda}, \] (4.6)
\( \sqrt{\cdot} \) denotes the branch of the square root such that \( \text{Im} \sqrt{z} > 0 \) for all \( z \in \mathbb{C}\setminus\mathbb{R}_+ \), and
we refer to \( J(H) \) as the Jensen sums. Notably, \( J(H) \) arises naturally from Jensen’s
formula in complex analysis. It follows immediately from the inequality [53, Lemma 1]
\[ |\lambda|^{1/2} |\text{Im} \sqrt{\lambda}| \leq \text{dist}(\lambda, \mathbb{R}_+) \leq 2|\lambda|^{1/2} |\text{Im} \sqrt{\lambda}|, \] (4.7)
that \( J(H) \) is equivalent to \( S_0(H) \)

\[
J(H) \leq S_0(H) \leq 2J(H).
\] (4.8)

The aim of the chapter is two-fold. On one hand, we shall establish upper bounds for the sums \( S_\varepsilon(H), \varepsilon \geq 0 \), and \( J(H) \). While the upper bounds for the sums \( S_\varepsilon(H), \varepsilon > 0 \), (i.e., the non-critical case) hold for arbitrary integrable potentials, the upper bounds for the sums \( J(H) \) (i.e., the critical case) are only valid for sub-classes of integrable potentials. On the other hand, corresponding lower bounds shall be proven for specific potentials, demonstrating optimality of our upper bounds in various senses. Moreover, in Section 3 we shall construct an integrable potential such that the sum \( J(H) = \infty \).

**Summary of main results**

Our analysis is based on identifying the square roots of eigenvalues of the Schrödinger operator \( H \) (4.2) with the zeros of an analytic function in the upper-half of the complex plane \( \mathbb{C}_+ \). The idea of using methods of complex analysis in the theory of non-self-adjoint Schrödinger operator on the half-line goes back to the pioneering papers of Naimark [108] and Levin [96], and reaches its culmination in the famous series of papers by Pavlov [112–114], who found the threshold between finitely and infinitely many eigenvalues in the case of a complex potential.

Let us first recall the notion of a Jost function, which will be useful for describing the basic ideas of the proofs, and then proceed to give an account of our main results.

**Jost functions**

Recall that it is well known [108, Theorems 2.2.1 and 2.3.1] that for any \( z \in \mathbb{C}_+ \), the Schrödinger equation on \( \mathbb{R}_+ \)

\[
-y'' + q(x)y = z^2y, \quad q \in L^1(\mathbb{R}_+)
\] (4.9)

has a unique solution \( e_+(\cdot,z) \) with the property that \( e_+(x,\cdot) \) is analytic on \( \mathbb{C}_+ \) for all \( x \geq 0 \) and

\[
e_+(x,z) = e^{ixz}(1 + o(1)), \quad \text{as} \quad x \to \infty
\] (4.10)

uniformly on compact subsets of \( \mathbb{C}_+ \). \( e_+(\cdot,z) \) is referred to as the *Jost solution*. The *Jost function* is defined as \( e_+(z) := e_+(0,z), z \in \mathbb{C}_+ \), and has the property that

\[
\lambda = z^2 \in \sigma_d(H) \iff e_+(z) = 0.
\] (4.11)
Moreover, the algebraic multiplicity (i.e., the rank of the Riesz projection) of $z^2$ as an eigenvalue of $H$ coincides with the multiplicity of $z$ as a zero of $e_+$ (see, for instance, [74, Theorem 5.4 and Lemma 6.2]).

**Upper bound for the non-critical case**

Our first result concerns a bound from above for the Lieb-Thirring sums $S_\varepsilon(H)$ in the non-critical case $\varepsilon > 0$. It is valid for Schrödinger operators with arbitrary integrable potentials.

**Theorem 4.1** (≡ Theorem 4.5). For every $\varepsilon > 0$, there exists a constant $K(\varepsilon) > 0$ depending only on $\varepsilon$, such that for any potential $q \in L^1(\mathbb{R}_+)$, we have

$$S_\varepsilon(H_q) = \sum_{\lambda \in \sigma_d(H_q)} \frac{\text{dist}(\lambda, \mathbb{R}_+)}{|\lambda|^{(1-\varepsilon)/2}} \leq K(\varepsilon) ||q||_1^{1+\varepsilon}. \quad (4.12)$$

Given a pair $(\alpha, \beta)$ of positive parameters, we define a generalised Lieb-Thirring sum $S_{\alpha, \beta}(H_q)$ by

$$S_{\alpha, \beta}(H_q) := \sum_{\lambda \in \sigma_d(H_q)} |\lambda|^\alpha \left[ \frac{\text{dist}(\lambda, \mathbb{R}_+)}{|\lambda|} \right]^\beta = \sum_{\lambda \in \sigma_d(H_q)} \frac{\text{dist}^\beta(\lambda, \mathbb{R}_+)}{|\lambda|^{\beta-\alpha}}. \quad (4.13)$$

In terms of such sums, Theorem 4.1 takes the form

$$S_{\alpha, 1}(H_q) \leq C_\alpha ||q||_1, \quad \forall \alpha > \frac{1}{2}. \quad (4.14)$$

We study such generalised Lieb–Thirring sums in more detail in Proposition 4.23.

The proof of Theorem 4.1 is based on the application of a result of Borichev, Golinskii and Kupin [24] concerning the Blaschke-type conditions on zeros of analytic functions on the unit disk $\mathbb{D}$ satisfying appropriate growth conditions at the boundary. An analytic function on $\mathbb{D}$ is constructed from the Jost function $e_+$ using a certain conformal mapping, and the growth conditions are verified by applying classical estimates for $e_+$.

**Upper bounds for the critical case**

Let us address upper bounds for the Jensen sums $J(H)$. We proceed by embarking on a study of sub-classes of $L^1(\mathbb{R}_+)$. To begin with, we introduce a pair of positive, continuous functions $a$ and $\hat{a}$ on $\mathbb{R}_+$, such that

$$\hat{a}(x) = \frac{x}{a(x)}, \quad a(x) = \frac{x}{\hat{a}(x)}, \quad x \in \mathbb{R}_+. \quad (4.15)$$
We will refer to $a$ and $\hat{a}$ as weight functions. We require that:

- $a$ is monotonically increasing.
- $\hat{a}$ is strictly monotonically increasing, $\hat{a}(0) = 0$ and $\hat{a}(\infty) = \infty$.

Introduce the norm

$$\|q\|_a := \int_0^\infty a(x)|q(x)|dx,$$  \hspace{1cm} (4.16)

which agrees with (4.4) for $a \equiv 1$. We consider sub-classes of $L^1(\mathbb{R}_+)$ of the form

$$Q_a := \{q \in L^1(\mathbb{R}_+) : \|q\|_a < \infty\}. \hspace{1cm} (4.17)$$

In its most general form, our upper bound for the Jensen sum reads as follows.

**Theorem 4.2** (= Theorem 4.8). Let $a$ and $\hat{a}$ be a pair of weight functions as described above. Assume also that

$$\int_1^\infty \frac{dx}{xa(x)} < \infty. \hspace{1cm} (4.18)$$

Then, for each potential $q \in Q_a$ and each $\delta \in (0, 1)$, we have

$$J(H_q) \leq y\log \left(\frac{1 + \delta}{(1 - \delta)^2}\right) + \frac{4}{\pi} \|q\|_a \int_{\frac{1}{y}}^{\hat{a}(\infty)} \frac{dx}{xa(x)}, \hspace{1cm} (4.19)$$

where $y = y(\delta, a, \|q\|_a) > 0$ is uniquely determined by

$$\hat{a} \left(\frac{1}{y}\right) \|q\|_a = \log(1 + \delta). \hspace{1cm} (4.20)$$

We emphasise that this upper bound is not applicable for arbitrary potentials $q \in L^1(\mathbb{R}_+)$. Loosely speaking, the conditions $\|q\|_a < \infty$ and (4.18) may contradict each other, as far as the growth of $a$ goes. An instructive family of integrable potentials is considered in Remark 4.11, namely,

$$q(x) = \frac{i}{x\log^\alpha(x)} \chi_{[e, \infty)}(x), \hspace{1cm} \alpha > 1, \hspace{1cm} x \in \mathbb{R}_+, \hspace{1cm} (4.21)$$

where $\chi$ denotes the indicator function. For $\alpha > 2$, there exists an appropriate weight function $a$, and Theorem 4.2 is applicable to $q$. For $1 < \alpha \leq 2$, such a weight function $a$ does not exist.

We do not claim that $J(H_q) = \infty$ for the potentials $q$ in (4.21) with $1 < \alpha \leq 2$. In Theorem 4.30, we construct an example of a potential for which the Jensen sum diverges, showing that Theorem 4.2 cannot be extended to all integrable potentials.
Theorem 4.2 is applied to obtain upper bounds for \( J(H) \) valid for two important specific classes of potentials.

(A) (See Corollary 4.9) Let \( p \in (0, 1) \) and \( a(x) = 1 + x^p \). Then for each potential \( q \in Q_d \), we have

\[
J(H_q) \leq \frac{4}{\pi} \|q\|_a \log (1 + \|q\|_a) + \frac{9}{p} \|q\|_a + 2. \tag{4.22}
\]

In [123], Safronov has also obtained a bound for the Jensen sum \( J(H) \), valid for potentials \( q \in L^1(\mathbb{R}_+) \) satisfying \( \|x^p q\|_1 < \infty \) for some \( p \in (0, 1) \). Comparatively, the above result (A) offers an improved asymptotic estimate for semiclassical Schrödinger operators (see Remark 4.10).

(B) (See Corollary 4.12) Suppose the potential \( q \in L^1(\mathbb{R}_+) \) is compactly supported. Then, for every \( R > 1 \) with \( \text{supp}(q) \subset [0, R] \), we have

\[
J(H_q) \leq 7 \left( \frac{1}{R} + \|q\|_1 \left( 1 + \log(1 + \|q\|_1) + \log R \right) \right). \tag{4.23}
\]

As we will see below, this bound is optimal in a certain asymptotic sense.

The proof of Theorem 4.2 centers around establishing improved estimates for the Jost function \( e_+ \) corresponding to potentials in a given sub-class \( Q_d \). These improved estimates are obtained by combining the arguments for the classical case with the following simple principle:

\[
0 < A \leq \min(X_1, X_2) \Rightarrow A = a(A) \hat{a}(A) \leq a(X_1) \hat{a}(X_2). \tag{4.24}
\]

The bound (4.19) of Theorem 4.2 is proven by using these improved estimates for \( e_+ \) in conjunction with Jensen’s formula. The proofs of Corollaries 4.9 and 4.12 amount to appropriate choices for \( a \) and \( \delta \).

Lower bounds for dissipative barrier potentials

The optimality of the above upper bounds can be addressed by studying corresponding lower bounds for Schrödinger operators with so-called dissipative barrier potentials. Precisely, for \( \gamma, R > 0 \), we consider the Schrödinger operator

\[
L_{\gamma R} := -\frac{d^2}{dx^2} + i\gamma \chi_{[0,R]} \quad \text{on} \quad L^2(\mathbb{R}_+) \tag{4.25}
\]

endowed with a Dirichlet boundary condition at 0. The dissipative barrier potentials find applications in the numerical computation of eigenvalues, where they are con-
sidered as a perturbation of a fixed background potential \[104, 130\]. We focus on establishing our estimates for large enough \( R \). Observe that \( \|i\gamma\chi_{[0,R]}\|_1 = \gamma R \).

**Theorem 4.3** (\(= \text{Theorem } 4.21\)). Suppose that \( R \geq 600(\gamma^{3/4} + \gamma^{-3/4}) \).

(i) We have the following lower bound

\[
2J(L_{\gamma,R}) \geq S_0(L_{\gamma,R}) \geq \frac{\gamma R}{16\pi} \log R.
\] (4.26)

(ii) Let \( 0 < \varepsilon < 1 \). Under the stronger assumption on \( R \):

\[
R \geq \frac{4}{e^2 \gamma} (64\pi)^{2/\varepsilon} + 1,
\] (4.27)

we have the lower bound

\[
S_{\varepsilon}(L_{\gamma,R}) \geq \frac{1}{256\pi\varepsilon} \left( \frac{\gamma R}{\log R} \right)^{1+\varepsilon}.
\] (4.28)

The estimate (4.26) shows that

\[
\sup_{0 \neq q \in L^1(\mathbb{R}^+)} \frac{S_0(Hq)}{\|q\|_1} = +\infty.
\]

An analogous, but slightly less explicit, result for Schrödinger operators on the whole real line has appeared in \[22\] (cf. Remark 4.22). Notably, our proofs seem to use rather different methods.

The main ideas in the proof of Theorem 4.3 are as follows. Starting from the Jost function of \( L_{\gamma,R} \), we construct a countable family of equations, each of which is in the form of a fixed point equation. We are able to use the contraction mapping principle to prove that each equation has a unique solution corresponding to exactly one zero of the Jost function \( e_+ \) (or, more precisely, one zero of the analytic continuation of \( e_+ \) to \( \mathbb{C} \)).

As it turns out, each equation has a convenient form that allows us to gain quantitative information about its solution, hence about an individual zero of \( e_+ \). Estimates for the different equations can be combined to obtain lower bounds for the sums \( J(L_{\gamma,R}) \) and \( S_{\varepsilon}(L_{\gamma,R}) \) as well as other quantities, such as the number of eigenvalues (see Corollary 4.18).

Finally, note that, when applied to the Schrödinger operators \( L_{\gamma,R} \) (4.25), the upper bound (4.23) gives the optimal asymptotic estimate (see Proposition 4.24)

\[
J(L_{\gamma,R}) = O(R \log R), \quad \text{as} \quad R \to \infty.
\] (4.29)
Divergent Jensen sum

As mentioned, while Theorem 4.2 provides an upper bound for $J(H)$ for a wide range of potentials, there exist integrable potentials to which it does not apply. It is therefore natural to ask whether or not it is possible to extend this upper bound to arbitrary integrable potentials. Our final result show that this is impossible.

**Theorem 4.4** (=Theorem 4.30). There exists a potential $q \in L^1(\mathbb{R}_+)$ such that $J(H_q) = \infty$.

The proof of this result uses two crucial ingredients. The first is an idea of Bögli [17], which allows one to construct a Schrödinger operator whose eigenvalues approximate the union of the eigenvalues of a given sequence of Schrödinger operators $L_n$, $n \in \mathbb{N}$. The second is the lower bound of Theorem 4.3 for the Jensen sum $J(L_{\gamma,R})$. Indeed, the given sequence of Schrödinger operators $L_n$ in our case shall have dissipative barrier potentials. Note that the explicit condition $R \geq 600(\gamma^{3/4} + \gamma^{-3/4})$ in Theorem 4.3 plays an important role in Theorem 4.4.

**Remark.** ($\mathbb{R}_+ \text{ vs } \mathbb{R}$). Given a potential $q \in L^1(\mathbb{R}_+)$, denote by $Q$ its even extension on the whole line. By Proposition 4.26 below, there is inclusion $\sigma_d(H_q) \subset \sigma_d(H_Q)$, counting multiplicities, for the discrete spectra of Dirichlet Schrödinger operator $H_q$ on $L^2(\mathbb{R}_+)$ and Schrödinger operator $H_Q$ on $L^2(\mathbb{R})$. Hence, the inequality

$$\sum_{\lambda \in \sigma_d(H_q)} \Phi(\lambda) \leq \sum_{\lambda \in \sigma_d(H_Q)} \Phi(\lambda), \quad q \in L^1(\mathbb{R}_+), \quad (4.30)$$

holds with an arbitrary nonnegative function $\Phi$ on the complex plane. Thereby, upper bounds, such as (4.12), for $H_q$ can be derived from the corresponding results for the operator $H_Q$. As an example, the spectral enclosure [69] mentioned above is a direct consequence of the result for the whole line [1, Theorem 4].

Several inequalities of Lieb–Thirring-type for Schrödinger operators with complex potentials on $L^2(\mathbb{R})$ are known nowadays, but neither covers completely the main results of the chapter. The result of Frank and Sabin [70, Theorem 16] in dimension one is (4.12) with $\epsilon > 1$. The case $\epsilon = 1$ is a consequence of [66, Theorem 1.3]. The result of Demuth, Hansmann and Katriel [53, Corollary 3] in dimension one reads

$$\sum_{\lambda \in \sigma_d(H_Q)} \frac{\text{dist}^{p+\epsilon}(\lambda, \mathbb{R}_+)}{|\lambda|^{3+\epsilon}} \leq C(p, \epsilon) \|Q\|_{L^p(\mathbb{R})}^p, \quad p \geq \frac{3}{2}, \quad \epsilon \in (0,1).$$

Recently, Bögli [19] has extended this result considerably by including a much wider class of sums. The results of both DHK and Bögli are not applicable for arbitrary $L^1$ potentials, hence do not imply Theorem 4.1.
4.2 Classes of potentials and inequalities for sums of eigenvalues

We believe that the results for Schrödinger operators with complex potentials on \( L^2(\mathbb{R}) \), analogous to our upper bounds, can be obtained along the same line of reasoning by using similar methods. The study of this problem should be carried out elsewhere.

Outline of the chapter

In Section 1, we focus on upper bounds for the Lieb–Thirring sums with an arbitrary potential \( q \in L^1(\mathbb{R}_+) \), and for the Jensen sums with potentials \( q \in \mathcal{Q}_d \). Section 2 is devoted to the spectral analysis of Schrödinger operators with dissipative barrier potentials and to the lower bounds for the Lieb-Thirring and Jensen sums with such potentials. In Section 3 we prove Theorem 4.4.

4.2 Classes of potentials and inequalities for sums of eigenvalues

As we mentioned earlier in the introduction, a complex number \( \zeta \in \mathbb{C}_+ \) belongs to the zero set \( Z(e_+) \) of the Jost function if and only if \( \lambda = \zeta^2 \in \sigma_d(H) \), and the zero multiplicity coincides with the algebraic multiplicity of the corresponding eigenvalue. Therefore, the divisor \( Z(e_+) \) (zeros counting multiplicities) has a precise spectral interpretation. In this section, we study this divisor using various results from complex analysis and hence obtain bounds for sums of Lieb-Thirring and Jensen types. Throughout the section, we shall let

\[
\mathbb{C}_+^0 := \{ z \in \mathbb{C} : \text{Im} z \geq 0, z \neq 0 \}.
\]

4.2.1 Bounds for Lieb–Thirring sums

Recall that the Lieb–Thirring sum for a Dirchlet Schrödinger operator \( H \) is given by

\[
S_\varepsilon(H) = \sum_{\lambda \in \sigma_d(H)} \text{dist}(\lambda, \mathbb{R}_+) \left| \frac{\lambda}{1+\varepsilon} \right|, \quad 0 \leq \varepsilon < 1.
\]

Our first result gives an upper bound for \( S_\varepsilon(H) \) in the non-critical case of \( \varepsilon > 0 \) and arbitrary \( q \in L^1(\mathbb{R}_+) \).

**Theorem 4.5** (= Theorem 4.1). For every \( \varepsilon > 0 \), there exists a constant \( K(\varepsilon) > 0 \), depending only on \( \varepsilon \), such that

\[
S_\varepsilon(H_q) \leq K(\varepsilon) \| q \|_1^{1+\varepsilon}.
\]  

4.3 Classes of potentials and inequalities for sums of eigenvalues

...
Proof. A key ingredient of the proof is the following well-known inequality for the Jost function (see, e.g., [131, Lemma 1])

\[
|e_+(z) - 1| \leq \exp \left\{ \frac{\|q\|_1}{|z|} \right\} - 1, \quad z \in \mathbb{C}_+^0. \tag{4.32}
\]

Let

\[ y := \frac{\|q\|_1}{\kappa} > 0, \quad \kappa := \log \frac{3}{2}. \]

By (4.32),

\[ |e_+(iy) - 1| \leq \frac{1}{2}, \quad |e_+(iy)| \geq \frac{1}{2}. \]

Consider the function

\[ g(z) := \frac{e_+(yz)}{e_+(iy)}, \quad z \in \mathbb{C}_+, \quad g(i) = 1. \]

By the definition of \( y \), we have

\[
|g(z)| \leq 2|e_+(yz)| \leq 2 \exp \left\{ \frac{\|q\|_1}{y|z|} \right\} = 2 \exp \left\{ \frac{\kappa}{|z|} \right\},
\]

\[
\log |g(z)| \leq \log 2 + \frac{\kappa}{|z|} < \log 2 \frac{1+|z|}{|z|}.
\]

To go over to the unit disk, we introduce a new variable,

\[ w = w(z) = \frac{z - i}{z + i} : \mathbb{C}_+ \to \mathbb{D}, \quad z = z(w) = i \frac{1+w}{1-w}. \tag{4.33} \]

Write \( f(w) := g(z(w)) \). An elementary inequality

\[
\frac{2}{1+|z|} \leq |1 - w(z)| \leq \frac{2\sqrt{2}}{1+|z|}, \quad z \in \mathbb{C}_+,
\]

gives the following bound for \( f \)

\[
\log |f(w)| \leq \frac{2\sqrt{2} \log 2}{|1+w|}, \quad f(0) = 1. \tag{4.34}
\]

The Blaschke-type conditions for zeros of such analytic functions in \( \mathbb{D} \) are obtained in [24] (see [25] for some advances)

\[
\sum_{\eta \in \mathbb{Z}(f)} (1 - |\eta|)|1 + \eta|^{\varepsilon} \leq K_1(\varepsilon), \quad \forall \varepsilon > 0,
\]
where $K_1(\varepsilon) > 0$ depends only on $\varepsilon$. Going back to the upper half-plane and using another elementary inequality

$$\frac{\Im z}{1 + |z|^2} \leq 1 - |w| \leq \frac{8\Im z}{1 + |z|^2},$$

(4.35)

we come to the following relation for the divisor $Z(g)$

$$\sum_{\xi \in Z(g)} \frac{\Im \xi}{1 + |\xi|^2} \frac{|\xi|^\varepsilon}{|\xi + i|^\varepsilon} \leq K_2(\varepsilon).$$

But $\xi \in Z(g)$ is equivalent to $\zeta = y\xi \in Z(e_+)$, so

$$\left(\frac{\kappa}{\|q\|_1}\right)^{1+\varepsilon} \sum_{\zeta \in Z(e_+)} \frac{\Im \zeta}{1 + \left(\frac{\kappa|\zeta|}{\|q\|_1}\right)^2} \frac{\kappa^\varepsilon}{\|q\|_1 + i} \leq K_2(\varepsilon).$$

The aforementioned spectral enclosure result ensures that $|\zeta| \leq \|q\|_1$ for $\zeta \in Z(e_+)$. It follows that both factors in the denominator are bounded from above by some constants depending only on $\varepsilon$. We come to

$$\sum_{\zeta \in Z(e_+)} (\Im \zeta) |\zeta|^\varepsilon \leq K(\varepsilon)\|q\|_1^{1+\varepsilon},$$

(4.36)

where a positive constant $K$ depends only on $\varepsilon$.

To complete the proof, we employ the inequality (4.7), mentioned in the introduction. So, (4.31) follows.

\[\square\]

4.2.2 Classes of potentials and Jensen sums

In the rest of the section, we study the behavior of the discrete spectrum for Schrödinger operators within special classes of potentials.

Let $a$ be a monotonically increasing and locally integrable, nonnegative function on $\mathbb{R}_+$. Consider the classes of complex-valued potentials

$$Q_a := \{q \in L^1(\mathbb{R}_+) : \int_0^\infty a(x)|q(x)|dx < \infty\}.$$

(4.37)

The weight function $a$ is fixed in the sequel, and dependence of constants on $a$ is sometimes omitted.
Define a function \( \hat{a} \) on \( \mathbb{R}_+ \) by
\[
\hat{a}(x) := \frac{x}{a(x)}, \quad x \in \mathbb{R}_+,
\]
and put
\[
\omega_a(x, z) := \hat{a}\left(1 \left| \frac{1}{z} \right| \int_x^\infty a(t)|q(t)|dt\right), \quad x \in \mathbb{R}_+, \quad z \in \mathbb{C}_0^0.
\]

**Proposition 4.6.** Assume that both \( a \) and \( \hat{a} \) are monotonically increasing functions on \( \mathbb{R}_+ \). Then the Jost solution admits the bound
\[
|e^{-izx}e_+(x, z) - 1| \leq \exp(\omega_a(x, z)) - 1, \quad x \in \mathbb{R}_+, \quad z \in \mathbb{C}_0^0.
\] (4.38)

**Proof.** We follow the arguments of M.A. Naimark for the classical case \( a \equiv 1 \).

The Jost solution is known to satisfy the Schrödinger integral equation
\[
e_+(x, z) = e^{ixz} + \int_x^\infty \frac{\sin((t-x)z)}{z}q(t)e_+(t, z)dt.
\]
The latter can be resolved by the successive approximations method.

Introduce a new unknown function
\[
f(x, z) := e^{-izx}e_+(x, z) - 1,
\]
which satisfies
\[
f(x, z) = g(x, z) + \int_x^\infty k(t-x, z)q(t)f(t, z)dt,
\]
\[
k(u, z) := \frac{\sin uz}{z}e^{iz}, \quad g(x, z) := \int_x^\infty k(t-x, z)q(t)dt.
\] (4.39)

Let
\[
f_1(x, z) := g(x, z), \quad f_{n+1}(x, z) = \int_x^\infty k(t-x, z)q(t)f_n(t, z)dt, \quad n \in \mathbb{N}.
\]

In view of an elementary bound for the kernel \( k \)
\[
|k(u, z)| \leq \min\left(u, \frac{1}{|z|}\right),
\]
and monotonicity of $a$ and $\hat{a}$, we see that

$$|k(u,z)| = \hat{a}(|k(u,z)|) a(|k(u,z)|) \leq \hat{a} \left( \frac{1}{|z|} \right) a(u),$$

(cf. (4.24).

We first estimate $f_1$. By (4.40),

$$|f_1(x,z)| \leq \int_x^\infty |k(t-x,z)||q(t)|dt \leq \hat{a} \left( \frac{1}{|z|} \right) \int_x^\infty a(t-x)|q(t)|dt \leq \omega_a(x,z).$$

Assume for induction that

$$|f_j(x,z)| \leq \frac{\omega_j^a(x,z)}{j!}, \quad j = 1, 2, \ldots, n. \quad (4.41)$$

We compute

$$\frac{d}{dx} \left[ \omega_a^{n+1}(x,z) \right] = (n+1) \omega_a^n(x,z) \frac{d}{dx} \left[ \omega_a(x,z) \right]$$

$$= -(n+1) \omega_a^n(x,z) \hat{a} \left( \frac{1}{|z|} \right) a(x)|q(x)|,$$

and so

$$|f_{n+1}(x,z)| \leq \int_x^\infty |k(t-x,z)||q(t)| \frac{\omega_a^n(t,z)}{n!} dt$$

$$\leq \frac{1}{n!} \hat{a} \left( \frac{1}{|z|} \right) \int_x^\infty a(t)|q(t)| \frac{\omega_a^n(t,z)}{n!} dt$$

$$= - \frac{1}{(n+1)!} \int_x^\infty \frac{d}{dt} \left[ \omega_a^{n+1}(t,z) \right] dt = \frac{\omega_a^{n+1}(x,z)}{(n+1)!}.$$

Hence, (4.41) indeed holds for all $n \in \mathbb{N}$.

It follows that the solution $f$ to (4.39), which is known to be unique, satisfies

$$|f(x,z)| \leq \sum_{n=1}^\infty |f_n(x,z)| \leq \exp \left( \omega_a(x,z) \right) - 1$$

(the latter series converges absolutely and uniformly on the compact subsets of $(x \in \mathbb{R}_+, z \in \mathbb{C}_+)$). The bound (4.38) follows. \qed
The above result for $a(x) = x^\alpha$, $\alpha \in [0, 1]$, is due to Stepin [131, Lemma 1]. The bound for the Jost function $e_+(z) = e_+(0, z)$ is (4.38) with $x = 0$:

$$|e_+(z) - 1| \leq \exp \{ \hat{a} \left( \frac{1}{|z|} \right) \|q\|_a \} - 1, \quad \|q\|_a := \int_0^\infty a(t)|q(t)|dt. \quad (4.42)$$

The following spectral enclosure result is a simple consequence of (4.42) and the basic property of zeros of $e_+$.

**Corollary 4.7.** Under the hypothesis of Proposition 4.6, define the value

$$\rho = \rho(a, q) := \inf \left\{ t > 0 : \hat{a}(\sqrt{t}) \geq \frac{\log 2}{\|q\|_a} \right\}. \quad (4.43)$$

Then the discrete spectrum $\sigma_d(H_q)$ is contained in the closed disk

$$\sigma_d(H_q) \subset B_{\rho^{-1}}(0).$$

The case $\hat{a}(\infty) < \log 2 \|q\|_a^{-1}$ implies that $\rho = \infty$, and so the discrete spectrum is empty.

As a matter of fact, in view of [69], we have a more precise inclusion

$$\sigma_d(H_q) \subset B_r(0), \quad r := \min(\rho^{-1}, \|q\|_1^2). \quad (4.44)$$

Theorem 4.8 (= Theorem 4.2). In addition to the hypothesis of Proposition 4.6, assume that

1. $\hat{a}$ is a continuous, strictly monotonically increasing function, and $\hat{a}(0) = 0$, $\hat{a}(\infty) = \infty$,

2. $$\int_1^\infty \frac{dx}{xa(x)} < \infty.$$
4.2 Classes of potentials and inequalities for sums of eigenvalues

Then, for each potential \( q \in Q_a \), and each \( \delta \in (0,1) \), the following bound for the Jensen sum holds

\[
J(H_q) \leq y \log \frac{1+\delta}{(1-\delta)^2} + \frac{4}{\pi} \|q\|_a \int_\frac{1}{2}^\infty \frac{dx}{x a(x)},
\]

where \( y = y(\delta, a, \|q\|_a) > 0 \) is uniquely determined by

\[
\hat{a} \left( \frac{1}{y} \right) \|q\|_a = \log(1 + \delta).
\]

**Proof.** The argument is similar to that in Theorem 4.5. It follows from (4.42) and (4.46) that

\[
|e_+(iy) - 1| \leq 1 + \delta - 1 = \delta, \quad |e_+(iy)| \geq 1 - \delta,
\]

so the normalized function

\[
g(z) := \frac{e_+(yz)}{e_+(iy)}, \quad g(i) = 1,
\]

satisfies

\[
\log |g(z)| \leq \log \frac{1}{1 - \delta} + \hat{a} \left( \frac{1}{y|z|} \right) \|q\|_a, \quad z \in \mathbb{C}_+.
\]

Introduce a new variable \( w \in \mathbb{D} \), related to \( z \in \mathbb{C}_+ \) by (4.33). For \( f(w) := g(z(w)) \) one has, as above, \( f(0) = 1 \) and

\[
\log |f(w)| \leq \log \frac{1}{1 - \delta} + \hat{a} \left( \frac{1}{y} \frac{1 - w}{1 + w} \right) \|q\|_a, \quad w \in \mathbb{D}.
\]

For \( w = re^{i\theta}, |\theta| \leq \pi \), it is easy to calculate

\[
\max_{0 \leq r \leq 1} \left| \frac{1 - re^{i\theta}}{1 + re^{i\theta}} \right| = \begin{cases} 1, & |\theta| \leq \frac{\pi}{2}, \\ |\tan \frac{\theta}{2}|, & \frac{\pi}{2} < |\theta| < \pi, \end{cases}
\]

so

\[
\log |f(w)| \leq \begin{cases} \log \frac{1+\delta}{1-\delta}, & |\theta| \leq \frac{\pi}{2}, \\ \log \frac{1}{1-\delta} + \hat{a} \left( \frac{1}{y} |\tan \frac{\theta}{2}| \right) \|q\|_a, & \frac{\pi}{2} < |\theta| < \pi. \end{cases}
\]
In view of assumption \((2)\), the Jensen formula provides
\[
\sum_{\eta \in \mathbb{Z}(f)} (1 - |\eta|) \leq \sum_{\eta \in \mathbb{Z}(f)} \log \frac{1}{|\eta|} \\
\leq \frac{1}{2} \log \frac{1 + \delta}{(1 - \delta)^2} + \frac{\|q\|_a}{\pi} \int_{\pi/2}^\pi \hat{a} \left( \frac{1}{y} \left( \tan \frac{\theta}{2} \right) \right) d\theta \\
= \frac{1}{2} \log \frac{1 + \delta}{(1 - \delta)^2} + \frac{2\|q\|_a}{\pi} \int_1^\infty \frac{\hat{a}(y^{-1} t)}{1 + t^2} dt,
\]
and hence
\[
\sum_{\eta \in \mathbb{Z}(f)} (1 - |\eta|) \leq \frac{1}{2} \log \frac{1 + \delta}{(1 - \delta)^2} + \frac{2\|q\|_a}{\pi} \int_1^\infty \frac{\hat{a}(y^{-1} t)}{t^2} dt \\
\leq \frac{1}{2} \log \frac{1 + \delta}{(1 - \delta)^2} + \frac{2\|q\|_a}{\pi y} \int_1^\infty \frac{dx}{xa(x)} =: B.
\]

Going back to the function \(g\) and the upper half-plane and using \((4.35)\), we come to
\[
\sum_{\xi \in \mathbb{Z}(g)} \frac{\text{Im } \xi}{1 + |\xi|^2} \leq B.
\]
The relation between \(Z(g)\) and \(Z(e_+)\) is straightforward
\[
\xi \in \mathbb{Z}(g) \iff \xi = y\xi \in \mathbb{Z}(e_+),
\]
and, hence,
\[
\sum_{\xi \in \mathbb{Z}(e_+)} \frac{\text{Im } \xi}{1 + |\xi|^2} \leq By. \tag{4.47}
\]

As it follows from \((4.42)\),
\[
\hat{a} \left( \frac{1}{|\xi|} \right) \|q\|_a < \log 2 \Rightarrow e_+(z) \neq 0.
\]
Therefore,
\[
\hat{a} \left( \frac{1}{|\xi|} \right) \|q\|_a \geq \log 2, \quad \xi \in \mathbb{Z}(e_+),
\]
and so (see the choice of \(y (4.46)\)), by monotonicity of \(\hat{a}\),
\[
\hat{a} \left( \frac{1}{|\xi|} \right) \|q\|_a > \hat{a} \left( \frac{1}{y} \right) \|q\|_a \Rightarrow \left| \frac{\xi}{y} \right| < 1.
\]
We conclude from (4.47), that
\[ \sum_{\zeta \in \mathbb{Z}(e_+)} \text{Im } \zeta \leq 2By, \]
and (4.45) follows. The proof is complete. \( \square \)

As a first application of the above result, we study Schrödinger operators \( H_q \) with potentials \( q \) satisfying \( \| (1 + x^p)q \|_1 < \infty \) for some \( p \in (0, 1) \). Taking \( a(x) := x^p \) and any fixed \( \delta \in (0, 1) \) (e.g., \( \delta = 1/2 \)) in Theorem 4.8 easily yields the inequality
\[ J(H_q) \leq C(p) \left( \int_0^\infty x^p |q(x)| dx \right)^{\frac{1}{1-p}}, \quad p \in (0, 1). \]
The following corollary of Theorem 4.8 offers a refinement of this bound.

**Corollary 4.9.** Let \( p \in (0, 1) \) and \( a(x) = 1 + x^p \). Then for each potential \( q \in Q_a \), the following inequality holds
\[ J(H_q) \leq \frac{4}{\pi} \|q\|_a \log (1 + \|q\|_a) + \frac{9}{p} \|q\|_a + 2. \] (4.48)

**Proof.** Put
\[ \delta := \exp \left( \min \left( \frac{1}{2} \|q\|_a, \kappa \right) \right) - 1 \in (0, \frac{1}{2}], \quad \kappa = \log \frac{3}{2}. \]
Then, by (4.46),
\[ A_0 := \frac{\log(1 + \delta)}{\|q\|_a} = \hat{a} \left( \frac{1}{y} \right) \leq \frac{1}{2} \quad \text{and} \quad \log \frac{1 + \delta}{(1 - \delta)^2} \leq \log 6. \]

Since \( \hat{a} \) is monotonically increasing, with \( \hat{a}(1) = \frac{1}{2} \), we must have \( y \geq 1 \). In particular, this implies that
\[ \frac{y^{-1}}{1 + y^{-1}} \geq \frac{y^{-1}}{1 + y^p} = \hat{a}(y^{-1}) = A_0, \quad \frac{1}{y} \geq \frac{A_0}{1 - A_0}, \]
and so
\[ 1 \leq y \leq \frac{1 - A_0}{A_0} \leq \frac{1}{A_0}. \] (4.49)
If \( \|q\|_a \geq 2\kappa \), then \( \delta = \frac{1}{2} \), so \( y \leq 3 \|q\|_a \). On the other hand, if \( \|q\|_a < 2\kappa \), then \( A_0 = \frac{1}{2} \), so \( y = 1 \) (\( \hat{a} \) is strictly monotonically increasing). We conclude that
\[ y \leq 3 \|q\|_a + 1. \] (4.50)
The right hand side of (4.45) is the sum of two terms. We bound the first one as
\[ A_1 := y \log \frac{1 + \delta}{(1 - \delta)^2} \leq \log 6 (3\|q\|_a + 1) < 6\|q\|_a + 2. \]

The second (integral) term reads
\[ A_2 := \frac{4}{\pi} \|q\|_a \int_{1/y}^{\infty} \frac{dx}{x(1 + x^p)}. \]

The integral may be computed, and bounded above, as
\[ \int_{1/y}^{\infty} \frac{dx}{x(1 + x^p)} = \frac{1}{p} \log \left( 1 + \frac{1}{y^p} \right) + \log y \leq \frac{1}{py^p} + \log y. \]

Using the upper bound (4.50) and the lower bound (4.49) for \( y \), we obtain
\[ A_2 \leq \frac{4}{\pi} \|q\|_a \left[ \log (1 + \|q\|_a) + \log 3 + \frac{1}{p} \right] \leq \frac{4}{\pi} \|q\|_a \log (1 + \|q\|_a) + \frac{3}{p} \|q\|_a. \]

The bound (4.48) follows by combining the bounds for \( A_1 \) and \( A_2 \).

**Remark 4.10.** In [123], Safronov also studies Schrödinger operators \( H_q \) on \( \mathbb{R}_+ \) with potentials \( q \) satisfying \( \|(1 + x^p)q\|_1 < \infty \) for some \( p \in (0, 1) \), and obtains the estimate
\[ J(H_q) \leq C(p) \left( \int_0^{\infty} x^p |q(x)| dx \left( \int_0^{\infty} |q(x)| dx \right)^p + \int_0^{\infty} |q(x)| dx \right). \] (4.51)

Consider the following Dirichlet Schrödinger operators on \( \mathbb{R}_+ \),
\[ H_h = -\frac{d^2}{dx^2} + q(xh), \quad h > 0, \]
where \( q \in L^1(\mathbb{R}_+) \) is fixed. A rescaling shows that \( h \to 0 \) is equivalent to a semiclassical limit. It can be seen that Corollary 4.9 gives
\[ J(H_h) = O(h^{-(1+p)} \log(\frac{1}{h})) \quad \text{as} \quad h \to 0, \]
while the estimate (4.51) gives
\[ J(H_h) = O(h^{-(1+2p)}) \quad \text{as} \quad h \to 0, \]
4.2 Classes of potentials and inequalities for sums of eigenvalues

hence our result offers an improved asymptotic estimate for $H_h$.

The next example is more delicate. It presents an integrable potential $q$ that is not covered by Theorem 4.8. More precisely, $q \notin Q_a$ for any weight function $a$ satisfying the assumptions of Theorem 4.8.

**Example 4.11.** Take $\alpha > 1$ and put

$$q(x) := \begin{cases} \frac{i}{\log^\alpha x}, & x \geq e, \\ 0, & 0 < x < e, \end{cases}$$

Then, $q \in L^1(\mathbb{R}_+)$. We distinguish two cases.

1. Assume that $\alpha > 2$. Choose $\beta$ from $1 < \beta < \alpha - 1$ and denote

$$a(x) := \begin{cases} \log^\beta x, & x \geq e^\beta, \\ \beta^\beta, & 0 < x < e^\beta, \end{cases}$$

so $a$ is a positive, monotonically increasing and continuous function on $\mathbb{R}_+$. Then,

$$\hat{a}(x) = \begin{cases} \frac{x}{\log^\beta x}, & x \geq e^\beta, \\ \beta^{-\beta} x, & 0 < x < e^\beta. \end{cases}$$

Since $\beta > 1$, both assumptions of Theorem 4.8 are met. Clearly, $\|q\|_a < \infty$, so the Jensen sum $J(H_q)$ is finite for this potential.

2. Let now $1 < \alpha \leq 2$. We claim that there is no such weight function $a$.

Assume on the contrary, that there are $a$ and $\hat{a}$, which satisfy the assumptions of Theorem 4.8, and $\|q\|_a < \infty$. Then, for $t \geq e$,

$$\infty > \int_t^\infty \frac{a(x)}{x \log^\alpha x} \, dx \geq a(t) \int_t^\infty \frac{dx}{x \log^\alpha x} = \frac{1}{\alpha - 1} \frac{a(t)}{(\log t)^{\alpha - 1}},$$

or

$$a(t) \leq C_1 (\log t)^{\alpha - 1}, \quad t \geq e.$$

But $\alpha - 1 \leq 1$, and so

$$\int_1^\infty \frac{dt}{ta(t)} = \infty.$$

A contradiction completes the proof.

Part 2 of the above example by no means claims that $J(H_q) = \infty$ for those potentials.

As a final consequence of Theorem 4.8, we study the Jensen sums for Schrödinger operators with compactly supported potentials.
Corollary 4.12. For any potential $q \in L^1(\mathbb{R}_+)$ with supp$(q) \subset [0,R]$, $R > 1$, the following inequality holds
\[
J(H_q) \leq 7 \left[ \frac{1}{R} + \|q\|_1 \left( 1 + \log(1 + \|q\|_1) + \log R \right) \right].
\] (4.53)

Proof. We choose the weight functions
\[
a(x) = \begin{cases} 1, & 0 < x \leq R, \\ \frac{\log x}{\log R}^2, & x \geq R, \end{cases} \quad \hat{a}(x) = \begin{cases} x, & 0 < x \leq R, \\ x \left( \frac{\log R}{\log x} \right)^2, & x \geq R. \end{cases}
\]
Since supp$(q) \subset [0,R]$, we have $\|q\|_a = \|q\|_1$.

Put
\[
\delta := \exp \left( \min(\|q\|_1 R, \kappa) \right) - 1 \in \left( 0, \frac{1}{2} \right], \quad \kappa = \log \frac{3}{2}.
\]
Clearly,
\[
\log(1 + \delta) = \min(\|q\|_1 R, \kappa) \leq \|q\|_1 R, \quad \frac{\log(1 + \delta)}{\|q\|_1} \leq R,
\]
and so the quantity $y$ defined in (4.46) is given by
\[
y = \frac{\|q\|_1}{\log(1 + \delta)}.
\]

The right hand side of (4.45) is the sum of two terms, $A = A_1 + A_2$. The first one is
\[
A_1 := y \log \frac{1 + \delta}{(1 - \delta)^2} = \|q\|_1 + y \log \frac{1}{(1 - \delta)^2} \leq \|q\|_1 \left\{ 1 + \frac{\log 4}{\log(1 + \delta)} \right\}
\]
\[
= \|q\|_1 \left\{ 1 + \frac{\log 4}{\min(\|q\|_1 R, \kappa)} \right\}.
\]

Hence,
\[
A_1 \leq \begin{cases} \|q\|_1 \left( 1 + \frac{\log 4}{\kappa} \right) < 5\|q\|_1, & \|q\|_1 R \geq \kappa, \\ \|q\|_1 + \frac{\log 4}{R} = \|q\|_1 R + \log 4 < \frac{\log 6}{R}, & \|q\|_1 R < \kappa. \end{cases}
\]

To estimate the second (integral) term $A_2$, note that $y^{-1} \leq R$, and so $A_2 = A_{21} + A_{22}$ with
\[
A_{21} := \frac{4}{\pi} \|q\|_1 \int_{\frac{1}{2}}^R \frac{dt}{t} = \frac{4}{\pi} \|q\|_1 \log \frac{\|q\|_1 R}{\log(1 + \delta)},
\]
\[
A_{22} := \frac{4}{\pi} \|q\|_1 \log^2 R \int_R^\infty \frac{dt}{t \log^2 t} = \frac{4}{\pi} \|q\|_1 \log R.
\]
Hence,
\[
A_2 \leq \frac{4}{\pi} \|q\|_1 \log R + \frac{4}{\pi} \|q\|_1 \log \frac{\|q\|_1 R}{\min(\|q\|_1 R, \kappa)},
\]
or
\[
A_2 \leq \begin{cases} 
\frac{4}{\pi} \|q\|_1 \left( \log R + \log(\|q\|_1 R) + \log \frac{1}{\kappa} \right), & \|q\|_1 R \geq \kappa, \\
\frac{4}{\pi} \|q\|_1 \log R, & \|q\|_1 R < \kappa.
\end{cases}
\]

A combination of the above bounds (with appropriate calculation of the constants) leads to (4.53), as claimed. \qed

**Remark 4.13.** The celebrated Blaschke condition for zeros of analytic functions on the upper half-plane reads (see [73, Section II.2, (2.3)])
\[
\sum_{z \in \mathcal{Z}(f)} \frac{\text{Im} z}{1 + |z|^2} < \infty.
\] (4.54)

It holds, for instance, for functions of bounded type (ratios of bounded analytic functions). In view of the spectral enclosure $|z| \leq \|q\|_1$, the bound $J(H_q) < \infty$ is equivalent to the Blaschke condition for zeros of the Jost function.

### 4.3 Dissipative barrier potentials

As in the introduction (see (4.25)), let $L_{\gamma,R}$ denote a Dirichlet Schrödinger operator on $\mathbb{R}_+$ with the potential
\[
q_{db} := i\gamma \chi_{[0,R]}, \quad \gamma, R > 0.
\] (4.55)

We fix $\gamma$ throughout this section and shall be interested in large $R$. The aim of the section is to prove the bounds for the Lieb-Thirring and Jensen sums of the eigenvalues of $L_{\gamma,R}$ for large enough $R$.

#### 4.3.1 Eigenvalues of Schrödinger operators with dissipative barrier potentials

The value $z^2 \in \sigma_d(L_{\gamma,R})$ if the equation
\[
-yy'' + i\gamma \chi_{[0,R]}(x)y = z^2 y
\] (4.56)
has a solution \( y \in L^2(\mathbb{R}_+) \) with \( y(0) = 0 \). An integration by parts with the normalized eigenfunction gives

\[
z^2 = i \int_0^\infty |y'(t)|^2 \, dt + i \gamma \int_0^\infty |y(t)|^2 \, dt \in \Gamma_+,
\]

\( \Gamma_+ := \{ \zeta \in \mathbb{C} : \text{Re} \zeta > 0, 0 < \text{Im} \zeta < \gamma \} \). (4.57)

It shall be convenient for us to work with two different branches \( \text{sq}_\pm \) of the square-root function. \( \text{sq}_\pm \) have branch-cuts along \( \mathbb{R}_{\pm} \), respectively, and the corresponding argument functions \( \text{arg}_\pm \) satisfy

\[
\text{arg}_+ (\zeta) \in [0, 2\pi), \quad \text{arg}_- (\zeta) \in [-\pi, \pi), \quad \zeta \in \mathbb{C}; \quad \text{sq}_+ (\zeta) = \sqrt{\zeta} e^{\frac{i}{2} \text{arg}_+(\zeta)}.
\]

Since the solutions of the equation (4.56) are obviously computable, we may characterise the eigenvalues of \( L_{\gamma,R} \) as the zeros of an explicit analytic function. Let

\[
\varphi_R(z) := (z - \text{sq}_+(z^2 - i\gamma)) e^{iR\text{sq}_+(z^2 - i\gamma)} - (z + \text{sq}_+(z^2 - i\gamma)) e^{-iR\text{sq}_+(z^2 - i\gamma)}.
\]

**Lemma 4.14.** For any \( R > 0 \) and any \( z \in \mathbb{C}_+ \) with \( z^2 \neq i\gamma \),

\[
z^2 \in \sigma_d (L_{\gamma,R}) \iff \varphi_R(z) = 0.
\]

**Proof.** Let \( R > 0 \) and \( z \in \mathbb{C}_+ \) such that \( z^2 \neq i\gamma \). Recall that \( e_+(\cdot, z) \) denotes the Jost solution. Since \( e_+(\cdot, z) \) spans the space of solutions of (4.56) in \( L^2(\mathbb{R}_+) \), we have

\[
z^2 \in \sigma_d (L_{\gamma,R}) \iff e_+(0, z) = 0.
\]

It suffices to show that \( e_+(0, z) = 0 \) if and only if \( \varphi_R(z) = 0 \). Since \( z \neq 0 \) and \( z^2 \neq i\gamma \), \( e_+ \) must satisfy

\[
e_+ (x, z) = \begin{cases} 
    c_1 (z) e^{ix \text{sq}_+(z^2 - i\gamma)} + c_2 (z) e^{-ix \text{sq}_+(z^2 - i\gamma)}, & 0 < x < R \\
    e^{ix}, & x \geq R,
\end{cases}
\]

for some \( c_j(z) \in \mathbb{C}, \, j = 1, 2 \). \( c_1 \) and \( c_2 \) are determined by imposing the continuity of \( e_+(\cdot, z) \) and \( \frac{d}{dx} e_+(\cdot, z) \) at the point \( R \),

\[
c_1(z) = \frac{\text{sq}_+(z^2 - i\gamma) + z}{2 \text{sq}_+(z^2 - i\gamma)} e^{-iR \left( \text{sq}_+(z^2 - i\gamma) - z \right)}, \\
c_2(z) = \frac{\text{sq}_+(z^2 - i\gamma) - z}{2 \text{sq}_+(z^2 - i\gamma)} e^{iR \left( \text{sq}_+(z^2 - i\gamma) + z \right)}.
\]
and so the expression for the Jost function $e_+(0, z)$ is

$$e^{-iRz}e_+(0, z) = \frac{(z + \text{sq}_+(z^2 - i\gamma))e^{-i\text{sq}_+(z^2 - i\gamma)} - (z - \text{sq}_+(z^2 - i\gamma))e^{i\text{sq}_+(z^2 - i\gamma)}}{2\text{sq}_+(z^2 - i\gamma)}$$

$$= \cos(R\text{sq}_+(z^2 - i\gamma)) - izR\sin(R\text{sq}_+(z^2 - i\gamma)).$$

Note that it is clear from this expression that $e_+$ is an entire function.

Finally, $z^2 \neq i\gamma$, so $e_+(0, z) = 0$ if and only if

$$\varphi_R(z) = -2\text{sq}_+(z^2 - i\gamma)e^{-iRz}e_+(0, z) = 0.$$

The proof is complete.

Note that, $\varphi_R(z_0) = 0$ for $z_0^2 = i\gamma$, but $z_0^2 \notin \sigma_d(L_{\gamma, R})$.

Our strategy is to derive a countable family of equations, each of which has a unique solution corresponding to exactly one zero of $\varphi_R$. Introduce a new variable $w$ by

$$w := \text{sq}_+(z^2 - i\gamma).$$

For $\text{Re} \ z > 0$, we have $z = \text{sq}_-(z^2)$ and so

$$z = \text{sq}_-(w^2 + i\gamma).$$

Consider the family of equations

$$w = G_{j, R}(w) := \frac{-B_j(w) + iA(w)}{2R}, \quad j \in \mathbb{N},$$

where

$$A(w) := \log \left| \frac{\text{sq}_-(w^2 + i\gamma) - w}{\text{sq}_-(w^2 + i\gamma) + w} \right|$$

and

$$B_j(w) := \text{arg}\left( \frac{\text{sq}_-(w^2 + i\gamma) - w}{\text{sq}_-(w^2 + i\gamma) + w} \right) + 2\pi j, \quad j \in \mathbb{N}.$$

Clearly,

$$2\pi \left( j - \frac{1}{2} \right) \leq B_j(w) < 2\pi \left( j + \frac{1}{2} \right), \quad j \in \mathbb{N}. $$

(4.60)
Lemma 4.15. Let $R > 0$. If $w \in \mathbb{C}_+$ solves equation (4.59), and $w^2 + i\gamma \in \mathbb{C}_+$, then $w^2 + i\gamma \in \sigma_d(L_{\gamma,R})$.

Proof. The equation (4.59) can be written as

$$w = G_{j,R}(w) = \frac{i}{2R} \left( \log - \left( \frac{\text{sq}_-(w^2 + i\gamma) - w}{\text{sq}_-(w^2 + i\gamma) + w} \right) + 2\pi i j \right)$$

where $\log$ denote the branch of the logarithm corresponding to $\arg$. Rearranging this equation, it holds that

$$(\text{sq}_-(w^2 + i\gamma) - w) e^{iRw} - (\text{sq}_-(w^2 + i\gamma) + w) e^{-iRw} = 0,$$

which is equivalent to $\varphi_R(z) = 0$, where $z$ is defined by (4.58). Finally, $w \neq 0$ implies $z^2 \neq i\gamma$, and the hypothesis $w^2 + i\gamma \in \mathbb{C}_+$ ensures that $z \in \mathbb{C}_+$ so, by Lemma 4.14, we have $z^2 = w^2 + i\gamma \in \sigma_d(L_{\gamma,R})$. \qed

From this point on, we shall restrict our attention to solutions of (4.59) in the angle

$$F_\infty = \{ w \in \mathbb{C} : \text{Re } w \leq 0 \leq \text{Im } w, \ |\text{Re } w| \geq 2|\text{Im } w| \}$$

$$= \{ re^{i\theta} : \pi - \arctan \frac{1}{2} \leq \theta \leq \pi, \ r \geq 0 \}$$

and its subsets

$$F_j := \{ w \in F_\infty : B_j(w) \geq 2|A(w)| \}, \quad j \in \mathbb{N}.$$
Since $B_{j+1}(w) = B_j(w) + 2\pi$, the family $\{F_j\}_{j \geq 1}$ is nested

$$F_j \subset F_{j+1}, \quad \bigcup_{j=1}^{\infty} F_j = F_\infty.$$ 

As $B_j(w) \geq \pi$ for all $w \in F_\infty$, and $A(0) = 0$, the set $F_j$ is nonempty for all $j \in \mathbb{N}$.

The next result establishes existence and uniqueness of solutions in the regions $F_j$ for each equation (4.59) and large enough $R$. Precisely, we assume that

$$R \geq C_0 \left( \gamma^{3/4} + \gamma^{-3/4} \right), \quad C_0 = 600. \quad (4.64)$$

**Proposition 4.16.** For all $R$ satisfying (4.64) and all $j \in \mathbb{N}$, the equation (4.59) has a unique solution in $F_\infty$ which lies in $F_j$. For different equations the solutions are different.

**Proof.** A key ingredient of the proof is the contraction mapping principle (see, e.g., [118, Theorem V.18]) on the complete metric space $(F_j, |\cdot|)$ with the usual absolute value on $\mathbb{C}$ as a distance.

Fix $j \in \mathbb{N}$. Suppose we can show that for $R$ satisfying (4.64),

(a) $G_{j,R} : F_j \to F_j$,

(b) $G_{j,R}$ is a strict contraction mapping.

Then, the map $G_{j,R} : F_j \to F_j$ has a unique fixed point, and so the equation $w = G_{j,R}(w)$ has a unique solution in $F_j$. Moreover, there are no solutions for the latter equation outside $F_j$. Indeed, any solution $w \in F_\infty$ satisfies

$$w = G_{j,R}(w) = \frac{-B_j(w) + iA(w)}{2R} \Rightarrow B_j(w) \geq 2|A(w)|$$

so $w \in F_j$. So, it suffices to prove the statements (a) and (b) above.

Put

$$w = u + iv, \quad z = \text{sq}_-(w^2 + i\gamma) = x + iy.$$ 

Let us show first that for each $w \in F_\infty$,

$$x = \Re \text{sq}_-(w^2 + i\gamma) \geq 0, \quad |y| = |\Im \text{sq}_-(w^2 + i\gamma)| \leq x = \Re \text{sq}_-(w^2 + i\gamma). \quad (4.65)$$

Indeed, the first inequality follows from the definition of $\text{sq}_-$. As for the second one, since $\Re (z^2) = \Re (w^2)$ and $|u| \geq 2v$, we have

$$u^2 - v^2 = x^2 - y^2, \quad x^2 = y^2 + u^2 - v^2 \geq y^2 + 3v^2 \Rightarrow |y| \leq x,$$
as claimed.

Step 1. To prove the statement (a), we show first that the following inequalities hold

1. \( \text{Re} \, G_{j,R}(w) < 0 \leq \text{Im} \, G_{j,R}(w), \ w \in F_\infty, \)

2. \( |\text{Re} \, G_{j,R}(w)| \geq 2 |\text{Im} \, G_{j,R}(w), \ w \in F_j. \)

In view of the definition of \( B_j(w) = -2R \text{Re} \, G_{j,R}(w), \) and the bounds (4.60) for \( B_j, \) the left inequality in (1) is obvious. To prove the right one, it suffices to show that \( A(w) \geq 0 \) for all \( w \in F_\infty. \) We write

\[
|z \pm w|^2 = |z|^2 + |w|^2 \pm 2 \text{Re} (\bar{w}z) = |z|^2 + |w|^2 \pm 2(ux + vy),
\]

and so

\[
|z - w|^2 - |z + w|^2 = -4(ux + vy).
\]

As we know, \( |u| \geq 2v \) for \( w \in F_\infty, \) and also \( x \geq |y|, \) by (4.65). Hence,

\[
|vy| \leq \left| \frac{|u|x}{2} \right| \leq |ux|, \quad ux + vy \leq ux + |vy| \leq ux + |ux| = 0,
\]

which implies

\[
|z - w|^2 - |z + w|^2 = -4(ux + vy) \geq 0, \quad A(w) = \log \left| \frac{z - w}{z + w} \right| \geq 0,
\]

and (1) follows. (2) is just the definition of \( F_j. \) So, \( G_{j,R} : F_j \to F_\infty. \)

Next, we want to check that for \( R \) satisfying (4.64),

\[
B_j(G_{j,R}(w)) \geq 2|A(G_{j,R}(w))|, \quad w \in F_j, \quad (4.66)
\]

or, in other words, \( G_{j,R}(w) \in F_j. \) It is shown above that, for \( w \in F_j, \) we have \( G_{j,R}(w) \in F_\infty \) and \( |A(G_{j,R}(w))| = A(G_{j,R}(w)) \geq 0. \) Then,

\[
A(G_{j,R}(w)) = \log \frac{\text{sq}_- (G_{j,R}^2(w) + i\gamma) - G_{j,R}(w)}{\gamma} \leq \log \frac{2(4|G_{j,R}(w)|^2 + \gamma)}{\gamma} = \log \left( \frac{8|G_{j,R}(w)|^2}{\gamma} + 2 \right).
\]

For \( w \in F_j \) one has \( 2|A(w)| \leq B_j(w), \) and so, by (4.60),

\[
|G_{j,R}(w)|^2 = \frac{A^2(w) + B_j^2(w)}{4R^2} \leq \frac{5B_j^2(w)}{16R^2} \leq \frac{5\pi^2}{4R^2} \left( j + \frac{1}{2} \right)^2.
\]
4.3 Dissipative barrier potentials

Hence,

\[ A(G_{j,R}(w)) \leq \log \left( 2 + \frac{10\pi^2 (j + \frac{1}{2})^2}{\gamma R^2} \right). \tag{4.67} \]

Clearly, \( 10\pi^2 < \gamma R^2 \) for \( R \) satisfying (4.64), so we come to

\[ A(G_{j,R}(w)) \leq \log \left( 2 + \left( j + \frac{1}{2} \right)^2 \right) < \log \left( 2 \left( j + \frac{1}{2} \right)^2 \right), \quad j \in \mathbb{N}. \tag{4.68} \]

Elementary calculus shows that

\[ \log 2 + 2 \log \left( j + \frac{1}{2} \right) < \pi \left( j - \frac{1}{2} \right), \quad j \in \mathbb{N}, \]

and so \( 2A(G_{j,R}(w)) \leq B_j(G_{j,R}(w)) \), which completes the proof of (4.66). The statement (a) is verified.

Step 2. We shall proceed with the statement (b). Let \( h \) denote the function

\[ h(w) := \frac{\text{sq}_-(w^2 + i\gamma) - w}{\text{sq}_-(w^2 + i\gamma) + w} = \frac{1}{i\gamma} \left( \text{sq}_-(w^2 + i\gamma) - w \right)^2. \tag{4.69} \]

In view of (4.65) and \( u = \text{Re} \, w \leq 0 \), it is easy to see that for each \( w \in F_{\infty} \),

\[ \text{sq}_-(w^2 + i\gamma) - w \in G := \{ \zeta \in \mathbb{C} : \text{Re} \, \zeta \geq 0, \ |\text{Im} \, \zeta| \leq \text{Re} \, \zeta \}, \]

and so \( h : F_{\infty} \rightarrow \overline{\mathbb{C}}_- \).

We conclude that the branch \( \log_- \) of the logarithm (corresponding to \( \arg_- \)) is continuously differentiable on \( h(F_{\infty}) \). By the expression for \( G_{j,R} \) in (4.61), \( G_{j,R} \) is continuously differentiable on \( F_{\infty} \). A direct computation yields

\[ \frac{d}{dw} G_{j,R}(w) = \frac{-i}{Rs\, \text{sq}_-(w^2 + i\gamma)}. \]

It is easy to show (see the definition of \( F_{\infty} \) (4.63)) that

\[ \min_{w \in F_{\infty}} |w^2 + i\gamma| = C\gamma, \quad C = \cos \left( 2 \arctan \frac{1}{2} \right) > \frac{1}{2}, \]

and so

\[ \left| \frac{d}{dw} G_{j,R}(w) \right| < 1, \quad w \in F_{\infty}, \]

as long as \( R \) satisfies (4.64). Hence, \( G_{j,R} : F_j \rightarrow F_j \) is a strict contraction mapping for such \( R \), completing the proof. \( \square \)
4.3.2 The number of eigenvalues and Lieb–Thirring sums for $L_{\gamma,R}$

Now that existence of solutions for the family of equations (4.59) has been established, we may prove lower bounds for Lieb–Thirring sums. Throughout the remainder of the section, we assume that $j \in \mathbb{N}$ and $R$ satisfies (4.64), and we let $w_j = w_j(\gamma,R) \in F_j$ denote the unique solution to the equation $w = G_{j,R}(w)$ in $F_j$.

As it turns out, one has to impose some restriction on the values $j$ to guarantee that $w_j$ corresponds to an eigenvalue. Precisely, assume that

$$1 \leq j \leq M_R := \left\lfloor \frac{1}{32\pi \log R} \gamma R^2 \right\rfloor.$$  

(4.70)

Lemma 4.17. For $R$ satisfying (4.64) and $j$ satisfying (4.70), the inequalities

$$-\frac{\gamma}{2} \leq \text{Im} w_j^2 \leq 0$$  

(4.71)

hold, so $z_j^2 = w_j^2 + i\gamma \in \mathbb{C}_+$ and $z_j^2 \in \sigma_d(L_{\gamma,R})$.

Proof. Firstly, we claim that for all $\gamma > 0$ and $R$ satisfying (4.64), we have

$$\Phi_\gamma(R) := \frac{\gamma R^2}{\log R} > \frac{C_0^2}{2\log C_0}.$$  

(4.72)

Since $R \geq 2C_0 > \sqrt{e}$, the function $\Phi_\gamma(R)$ is monotonically increasing and for each $\gamma > 0$

$$\Phi_\gamma(R) \geq f(\gamma) := C_0^2 \frac{\gamma^3/4 + \gamma^{-3/4}}{\log C_0 + \log \left(\gamma^{3/4} + \gamma^{-3/4}\right)} = C_0^2 \frac{\gamma^3 + 2\gamma^{3/2} + 1}{\sqrt{\gamma} \log C_0 + \sqrt{\gamma} \log \left(\gamma^{3/2} + 1\right)} - \frac{3}{4} \sqrt{\gamma} \log \gamma.$$  

Since $f(\gamma) \leq f(\gamma^{-1})$, $0 < \gamma \leq 1$, and $C_0 > e^2$, we see that

$$\min_{\gamma > 0} f(\gamma) = \min_{0 < \gamma \leq 1} f(\gamma) \geq \frac{C_0^2}{\log C_0 + \log 2 + \frac{3}{2e}} > \frac{C_0^2}{\log C_0 + 2} > \frac{C_0^2}{2\log C_0},$$

proving (4.72).

Next, we have

$$M_R > \frac{\Phi_\gamma(R)}{32\pi} - 1 > \frac{1}{32\pi} \frac{C_0^2}{2\log C_0} - 1 \geq 1,$$  

(4.73)
as long as
\[ \frac{C_0^2}{2 \log C_0} > 64 \pi, \]
which certainly true for the value \( C_0 \) in (4.64). By (4.73),
\[ \frac{\Phi_\gamma(R)}{32 \pi} > 2, \quad \frac{\Phi_\gamma(R)}{96 \pi} > \frac{2}{3} > \frac{1}{2}. \]
We assume that \( 1 \leq j \leq M_R \), so
\[ j + \frac{1}{2} \leq \frac{\Phi_\gamma(R)}{32 \pi} + \frac{1}{2} < \frac{\Phi_\gamma(R)}{24 \pi} = \frac{1}{24 \pi} \log R. \tag{4.74} \]

Since \( A(w_j) \geq 0, B_j(w_j) > 0 \), we have
\[
w_j^2 = G_{j,R}(w_j) = \frac{B_j^2(w_j) - A^2(w_j) - 2B_j(w_j)A(w_j)}{4R^2}, \tag{4.75}
\]
\[ \text{Im} w_j^2 = -\frac{B_j(w_j)A(w_j)}{2R^2} \leq 0. \]

To prove the lower bound in (4.71), we apply (4.68) and (4.74)
\[ A(w_j) \leq \log 2 + 2 \log \left( j + \frac{1}{2} \right) < 2 \log \gamma + 4 \log R, \]
and hence
\[ B_j(w_j)A(w_j) \leq 4 \pi \left( j + \frac{1}{2} \right) \left( \log \gamma + 2 \log R \right). \]
But \( R > \gamma^{3/4}, \log R > \frac{3}{4} \log \gamma \), and so, by (4.74),
\[ \log \gamma + 2 \log R < \frac{10}{3} \log R, \quad B_j(w_j)A(w_j) \leq \frac{1}{6} \frac{\gamma R^2}{\log R} \cdot \frac{10}{3} \log R < \gamma R^2. \]
The lower bound in (4.71) follows. The remaining claims follow from an application of Lemma 4.15. The proof is complete.

The result of Lemma 4.17 immediately implies a lower bound for the number \( N(L_{\gamma,R}) \) of eigenvalues of \( L_{\gamma,R} \), counting algebraic multiplicities.

**Corollary 4.18.** For \( R \) satisfying (4.64), we have the lower bound
\[ N(L_{\gamma,R}) \geq \left\lfloor \frac{1}{32 \pi \log R} \gamma R^2 \right\rfloor. \]

The next result amplifies the above corollary and will be used in our study of the sums \( S_{\alpha,\beta}(H_q) \) below. An analogous result for Schrödinger operators on the real line
has previously been obtained by Cuenin in [44, Theorem 4], by a different method. Let \( N(L_{\gamma, R}; \Omega) \) denote the number of eigenvalues of \( L_{\gamma, R} \) in a given region \( \Omega \subset \mathbb{C} \), counting algebraic multiplicities.

**Proposition 4.19.** There exist constants \( R_0, C_1 > 0 \), depending only on \( \gamma \), such that for the regions

\[
\Sigma_R := \left\{ \lambda \in \mathbb{C} : \frac{\gamma}{2} \leq \text{Im} (\lambda) \leq \gamma, \frac{C^{-1} R^2}{\log^2 R} \leq |\lambda| \leq \frac{C_1 R^2}{\log^2 R} \right\}
\]  

and all \( R \geq R_0 \), we have

\[
N(L_{\gamma, R}; \Sigma_R) \geq \frac{1}{128 \pi \log R}.
\]  

**Proof.** In this proof, we shall say that a statement holds for large enough \( R \) if there exists \( R_0 = R_0(\gamma) > 0 \) such that the statement holds for all \( R \geq R_0 \). Furthermore, \( C = C(\gamma) > 0 \) will denote a constant that may change from line to line.

Consider the unique solution \( w_j := w_j(\gamma, R) \) of the equation \( \lambda_j = G_{j, R}(w) \) in \( F_j \), which exists for large enough \( R \), with

\[
\left[ \frac{1}{64 \pi \log R} \right] \leq j \leq \left[ \frac{1}{32 \pi \log R} \right].
\]  

By Lemma 4.17, \( \lambda_j := w_j^2 + i \gamma \) is an eigenvalue of \( L_{\gamma, R} \) with \( \frac{\gamma}{2} \leq \text{Im} (\lambda_j) \leq \gamma. \)

By (4.67), we have

\[
|A(w_j)| = |A(G_{j, R}(w_j))| \leq \log \left( 2 + \frac{10 \pi^2 (j + \frac{1}{2})^2}{\gamma R^2} \right) \leq CR
\]  

for large enough \( R \). Using the inequality \( B_j(w_j) \geq 2 \pi (j - \frac{1}{2}) \) and the lower bound in (4.78), we have

\[
|\lambda_j| \geq |w_j|^2 - \gamma = \frac{|B_j(w_j)|^2 + |A(w_j)|^2}{4R^2} - \gamma \geq \frac{CR^2}{\log^2 R}
\]  

for large enough \( R \). On the other hand, using the inequality \( B_j(w_j) \leq 2 \pi (j + \frac{1}{2}) \) and the upper bound in (4.78), we have

\[
|\lambda_j| \leq \frac{|B_j(w_j)|^2 + |A(w_j)|^2}{4R^2} + \gamma \leq \frac{CR^2}{\log^2 R}
\]
for large enough $R$. It follows that $\lambda_j \in \Sigma_R$ for some constant $C_1 = C_1(\gamma) > 0$ and all large enough $R$. Finally, we have

$$N(L_{\gamma,R}; \Sigma_R) \gtrsim \left[ \frac{1}{32\pi \log R} \right] - \left[ \frac{1}{64\pi \log R} \right] \gtrsim \frac{\gamma R^2}{128\pi \log R}$$

for large enough $R$, completing the proof. □

**Remark 4.20.** An upper bound for the number of eigenvalues for Schrödinger operators with potentials of the form $q_R = q + i\gamma \chi_{[0,R]}$, where $q$ is compactly supported, is obtained in [129, Theorem 8]

$$N(H_{q_R}) \leq \frac{11}{\log 2} \frac{\gamma R^2}{\log R} \quad (4.79)$$

for large enough $R$. Our particular case corresponds to $q \equiv 0$ and demonstrates that (4.79) is optimal.

The result of Theorem 4.5 states that for each $\varepsilon > 0$ there exists a constant $K(\varepsilon) > 0$, independent from $q$, so that

$$S_\varepsilon(H_q) \leq K(\varepsilon) \|q\|_1^{1+\varepsilon}$$

for any integrable potential $q$. Our goal here is to obtain corresponding lower bounds for the operators $L_{\gamma,R}$ with potentials $q_{db}$ (4.55) and, thereby, to demonstrate the optimal character of this upper bound with respect to $\varepsilon$. Precisely, we will show that the value $S_0(L_{\gamma,R})$ tends to infinity fast enough as $R \to \infty$.

**Theorem 4.21** (= Theorem 4.3). Suppose that $R$ satisfies (4.64).

(i) We have the lower bound

$$S_\varepsilon(L_{\gamma,R}) \gtrsim \frac{q_{db}}{16\pi} \log R = \gamma R \log R \quad (4.80)$$

(ii) Let $0 < \varepsilon < 1$. Under the stronger assumption on $R$

$$R \geq \frac{4}{e^2 \gamma} (64\pi)^{2/\varepsilon} + 1, \quad (4.81)$$

we have the lower bound

$$S_\varepsilon(L_{\gamma,R}) \gtrsim \frac{1}{256\pi \varepsilon} \frac{(\gamma R)^{1+\varepsilon}}{\log^{\varepsilon} R} \quad (4.82)$$
Proof. (i). The bound from below for $S_0(L_{\gamma,R})$ arises when we take a subset of the eigenvalues, precisely, $\lambda_j = z_j^2 = w_j^2 + i\gamma$, with $j$ from (4.70). So, for $\varepsilon = 0$ we have, in view of Lemma 4.17,

$$S_0(L_{\gamma,R}) \geq \sum_{j=1}^{M_R} \text{Im}(w_j^2 + i\gamma) \geq \frac{\gamma}{2} \sum_{j=1}^{M_R} \frac{1}{\sqrt{\gamma} + |w_j|}. \quad (4.83)$$

But, owing to (4.60),

$$|w_j|^2 = |G_{j,R}(w_j)|^2 = \frac{|A(w_j)|^2 + |B_j(w_j)|^2}{4R^2} \leq \frac{5|B_j(w_j)|^2}{16R^2} \leq \frac{5\pi^2}{4R^2} \left( j + \frac{1}{2} \right),$$

and so

$$S_0(L_{\gamma,R}) \geq \frac{\gamma}{2} \sum_{j=1}^{M_R} \frac{1}{\sqrt{\gamma} + \frac{2\pi}{\gamma}(j + 1)}.$$ An elementary inequality

$$\sum_{j=1}^{N} \frac{1}{a+b(j+1)} > \int_{\frac{a}{2}}^{N+1} \frac{dx}{a+bx} = \frac{1}{b} \log \frac{a+b(N+1)}{a+2b}$$

with $a = \sqrt{\gamma}$, $b = 2\pi R^{-1}$, $N = M_R$, gives

$$S_0(L_{\gamma,R}) \geq \frac{\gamma R}{4\pi} \log \frac{\sqrt{\gamma} + 2\pi R^{-1}(M_R + 1)}{\sqrt{\gamma} + \frac{2\pi}{\gamma}(j + 1)} \geq \frac{\gamma R}{4\pi} \log \frac{1 + \frac{\sqrt{\gamma} R}{16\log R}}{1 + \frac{4\pi}{\sqrt{\gamma} R}}. \quad (4.84)$$

Let us check that for $R$ satisfying (4.64), one has

$$\frac{1 + \frac{\sqrt{\gamma} R}{16\log R}}{1 + \frac{4\pi}{\sqrt{\gamma} R}} > R^{1/4}, \quad \frac{\sqrt{\gamma} R}{16\log R} + 1 > R^{1/4} + \frac{4\pi}{\sqrt{\gamma} R^{3/4}}.$$ Indeed,

$$\frac{\sqrt{\gamma} R^{3/4}}{16\log R} = \frac{\gamma^{1/2}R^{2/3}}{16} \frac{R^{1/12}}{\log R} > C_0^{2/3} \frac{e}{16} > 1$$

as long as

$$C_0 > \left( \frac{192}{e} \right)^{3/2},$$

which is true for $C_0$ in (4.64) (at this point the value $C_0 = 600$ comes about). Next,

$$\frac{4\pi}{\sqrt{\gamma} R^{3/4}} = \frac{4\pi}{\gamma^{1/2}R^{2/3}R^{1/12}} < \frac{4\pi}{C_0^{2/3}} < 1.$$
as long as $C_0 > (4\pi)^{3/2}$. The bound (4.80) follows directly from (4.84).

(ii). We have, as above in (i),

\[
S_\varepsilon(L_\gamma R) \geq \frac{\gamma^{1+\varepsilon} R}{2} \sum_{j=1}^{M_R} \frac{1}{\gamma^{1-\varepsilon} + |w_j|^{1-\varepsilon}} \geq \frac{\gamma^{1+\varepsilon} R}{2} \sum_{j=1}^{M_R} \frac{1}{1 + \left(\frac{2\pi}{\sqrt{\gamma R}}(j+1)\right)^{1-\varepsilon}},
\]  

(4.85)

and so

\[
S_\varepsilon(L_\gamma R) \geq \frac{\gamma^{1+\varepsilon} R}{4\pi^2} \int_{\beta_1}^{\beta_2} \frac{dy}{1 + y^{1-\varepsilon}}, \quad \beta_1 := \frac{4\pi}{\sqrt{\gamma R}}, \quad \beta_2 := \frac{2\pi(M_R + 1)}{\sqrt{\gamma R}}.
\]

An elementary inequality $1 + y^{1-\varepsilon} \leq 2^\varepsilon (1 + y)^{1-\varepsilon}$ leads to the bound

\[
S_\varepsilon(L_\gamma R) \geq \frac{\gamma^{1+\varepsilon} R}{4\pi^2} \int_{\beta_1}^{\beta_2+1} \frac{dy}{t^{1-\varepsilon}} = \frac{\gamma^{1+\varepsilon} R}{4\pi^2\varepsilon^2} \left\{ (1 + \beta_2)^\varepsilon - (1 + \beta_1)^\varepsilon \right\}
\]

\[
= I_1 - I_2.
\]

We apply once again $(1 + \beta_2)^\varepsilon \geq 2^\varepsilon - 1(1 + \beta_2^\varepsilon)$ to estimate the first term

\[
I_1 \geq \frac{\gamma^{1+\varepsilon} R}{8\pi\varepsilon} (1 + \beta_2^\varepsilon) \geq \frac{\gamma^{1+\varepsilon} R}{8\pi\varepsilon} \left( \frac{2\pi(M_R+1)}{\sqrt{\gamma R}} \right)^\varepsilon > \frac{(\gamma R)^{1+\varepsilon}}{128\pi\varepsilon^2} \frac{1}{\log^\varepsilon R}.
\]  

(4.86)

Concerning the second term, note that (4.81) implies $\sqrt{\gamma R} > 8$, and so

\[(1 + \beta_1)^\varepsilon = \left(1 + \frac{4\pi}{\sqrt{\gamma R}}\right)^\varepsilon < 1 + \frac{\pi}{2} < \pi.
\]

Then

\[
I_2 \leq \frac{\gamma^{1+\varepsilon} R}{4\varepsilon^2 2^\varepsilon} = \frac{(\gamma R)^{1+\varepsilon}}{4\varepsilon^2 \varepsilon} \frac{1}{(\sqrt{\gamma R})^\varepsilon} < \frac{(\gamma R)^{1+\varepsilon}}{4\varepsilon} \frac{1}{(\sqrt{\gamma R})^\varepsilon}.
\]

But, under assumption (4.81),

\[
\sqrt{\gamma R} = \sqrt{\gamma R^{1/2}} \frac{R^{1/2}}{\log R} \geq \frac{\sqrt{\gamma e}}{2} R^{1/2} \geq (64\pi)^{1/\varepsilon},
\]

so

\[
\left(\frac{\log R}{\sqrt{\gamma R}}\right)^\varepsilon \leq \frac{1}{64\pi}, \quad \frac{1}{(\sqrt{\gamma R})^\varepsilon} \leq \frac{1}{64\pi \log^\varepsilon R}.
\]

Hence,

\[
I_2 \leq \frac{(\gamma R)^{1+\varepsilon}}{256\pi\varepsilon \log^\varepsilon R}.
\]

Comparing the latter with (4.86), we come to (4.82). The proof is complete.
Remark 4.22. The same methods lead to lower bounds for more general sums, which were considered in [22]. Let \( p \geq 1 \). A slight modification of the proof of Theorem 4.21 (i) yields
\[
\sum_{\lambda \in \sigma_d(L, R)} \frac{\text{dist}^p(\lambda, \mathbb{R}_+)}{|\lambda|^{1/2}} \geq \frac{\gamma^p R \log R}{8\pi \cdot 2^p},
\] (4.87)
provided \( R \) satisfies (4.64). Indeed, the only place in the proof of Theorem 4.21 (i) that needs to be modified is (4.83), and there we use the inequality
\[
\text{Im} (w_j^2 + i\gamma)^p \geq (\gamma/2)^p.
\]
Furthermore, by the spectral enclosure [69] mentioned in the introduction, we have
\[
|\lambda|^{s-1/2} \leq \|q_{db}\|_4^{2s-1} = (\gamma R)^{2s-1}, \quad \lambda \in \sigma_d(L, R), \quad s \geq \frac{1}{2},
\]
so it follows from (4.87) that
\[
\sum_{\lambda \in \sigma_d(L, R)} \frac{\text{dist}^p(\lambda, \mathbb{R}_+)}{|\lambda|^s} \geq \frac{1}{8\pi \cdot 2^p} \frac{\gamma^p R \log R}{(\gamma R)^{2s-1}}.
\] (4.88)

Now take \( R = n \) and \( \gamma = n^{-1} \) for \( n \in \mathbb{N} \). Then, \( R \) satisfies (4.64), and so (4.88) holds, for large enough \( n \). Noting that \( \|q_{db}\|_{LP(R)}^p = \gamma^p R \) and \( \gamma R = 1 \), and taking the limit \( n \to \infty \), we conclude that
\[
\sup_{0 \neq q \in LP(R^+) \cap L^1(R^+)} \frac{1}{\|q\|_{LP(R^+)}^p} \sum_{\lambda \in \sigma_d(H_q)} \frac{\text{dist}^p(\lambda, \mathbb{R}_+)}{|\lambda|^s} = \infty.
\] (4.89)
In view of Proposition 4.26 below, the statement (4.88) holds analogously for Schrödinger operators on \( L^2(\mathbb{R}) \) with symmetric potentials \( i\gamma \chi_{[-R, R]} \), hence (4.89) holds for Schrödinger operators on \( L^2(\mathbb{R}) \), which implies [22, Theorem 9].

Recall that the generalised Lieb–Thirring sum \( S_{\alpha, \beta}(H_q) \) is defined by (4.13). The problem we are interested in now is the range of positive parameters \( (\alpha, \beta) \) for which
\[
\mathcal{J}_{\alpha, \beta} := \sup_{0 \neq q \in L^1(\mathbb{R})} \frac{S_{\alpha, \beta}(H_q)}{\|q\|_1} < \infty.
\]
The results are illustrated in Figure 4.2.

Proposition 4.23. We have
\[
\mathcal{J}_{\alpha, \beta} < \infty, \quad \text{for } \alpha > \frac{1}{2}, \beta \geq 1,
\] (4.90)
and

\[\mathcal{J}_{\alpha, \beta} = \infty, \quad \text{for } \alpha > 0, \ 0 < \beta < 1, \ \text{and} \ 0 < \alpha \leq \frac{1}{2}, \ \beta = 1. \quad (4.91)\]

**Proof.** Theorem 4.5 implies that we have \(\mathcal{J}_{\alpha, 1} < \infty\) for \(\alpha > \frac{1}{2}\). Furthermore, by \(\text{dist}(\lambda, \mathbb{R}^+) \leq |\lambda|\), the function \(f(\beta) = S_{\alpha, \beta}(H_q)\) is monotone decreasing for fixed \(\alpha\), from which (4.90) follows.

By Proposition 4.19, for \(\alpha > 0\) and \(0 < \beta < 1\), we have

\[
S_{\alpha, \beta}^{2\alpha}(H_q) \geq N(L_{\gamma, R}; \Sigma_R) \inf_{\lambda \in \Sigma_R} \left( \frac{\text{dist}(\lambda, \mathbb{R}^+)}{|\lambda|} \right)^{\beta} |\lambda|^\alpha \\
\geq \frac{1}{128\pi \log R} \left( \frac{\gamma}{2} \right)^{\beta} \left( \frac{\min\{C_1, C_1^{-1}\} R^2}{\log^2 R} \right)^{\alpha - \beta} \\
= C \frac{R^{2(1-\beta)}}{(\log R)^{1+2\alpha-2\beta}} (\gamma R)^{2\alpha}
\]

for some constant \(C = C(\gamma) > 0\) and all large enough \(R\). The first statement in (4.91) follows by considering the limit \(R \to \infty\).

By (4.88) with \(p = \beta = 1\) and \(s = 1 - \alpha \geq \frac{1}{2}\), we have

\[
S_{\alpha, \beta}^{2\alpha}(L_{\gamma, R}) = \sum_{\lambda \in \sigma_d(L_{\gamma, R})} \frac{\text{dist}(\lambda, \mathbb{R}^+)}{|\lambda|^{1-\alpha}} \geq \frac{1}{16\pi} (\gamma R)^{2\alpha} \log R
\]
for large enough $R$. The second statement in (4.91) follows by again considering the limit $R \to \infty$.

We are in a position now to obtain a two-sided bound for the Jensen sums $J(L_{\gamma,R})$. Recall that $\|q_{db}\|_1 = \gamma R$.

**Proposition 4.24.** For all $R$ satisfying (4.64), the following two-sided inequality holds

$$\frac{1}{32\pi} \leq \frac{J(L_{\gamma,R})}{\gamma R \log R} \leq 42. \quad (4.92)$$

**Proof.** The lower bound is a direct consequence of (4.80) and (4.8). To prove the upper bound, we apply Corollary 4.12, so

$$J(L_{\gamma,R}) \leq 7 \left[ \frac{1}{R} + \gamma R + \gamma R \log R + \gamma R \log(1 + \gamma R) \right].$$

Note that (4.64) implies $R > e$ and $R^2 > \gamma + \gamma^{-1} + 1$. Hence,

$$\frac{1}{R} < \gamma R \log R, \quad \gamma R < \gamma R \log R, \quad \log(1 + \gamma R) < 3 \log R,$$

and inequality (4.92) follows. \qed

## 4.4 An integrable potential with divergent Jensen sum

The aim of this section is to construct a potential $q_\infty \in L^1(\mathbb{R}_+)$ such that $J(H_{q_\infty}) = \infty$. We shall begin, in Sections 4.4.1 and 4.4.2, by collecting some well-known facts about Schrödinger operators on both the half-line and the full real line. We shall then proceed to prove two spectral approximation lemmas in Section 4.4.3. These will give us information on the eigenvalues of Schrödinger operators on the half-line, for potentials consisting of a sum of compactly supported functions whose supports are separated from one another by large enough distances. The consideration of Schrödinger operators on the full real line is required in order to formulate one of these lemmas. With these tools at hand, the potential $q_\infty$ is constructed in Section 4.4.4.

### 4.4.1 Case of the half-line

Consider the following differential equation on the positive half-line $\mathbb{R}_+$

$$h[y] := -y'' + q(x)y = z^2y, \quad q \in L^1(\mathbb{R}_+), \quad z \in \mathbb{C}_+, \quad \text{ (4.93)}$$
where the potential $q$ may be complex-valued. There exists a unique pair of solutions $e_{\pm}(x, z; q)$ of (4.93), such that $e_{\pm}(x, z; q)$ are analytic on the upper half-plane $\mathbb{C}_+$, and

\begin{align}
e_+(x, z; q) & = e^{ixz}(1 + o(1)), \quad e'_+(x, z; q) = ize^{ixz}(1 + o(1)), \\
e_-(x, z; q) & = e^{-ixz}(1 + o(1)), \quad e'_-(x, z; q) = -ize^{-ixz}(1 + o(1)),
\end{align}

(4.94)
as $x \to +\infty$, uniformly on compact subsets of $\mathbb{C}_+$ (see, e.g., [108, Sections 2.2 and 2.3]). The Wronskian satisfies

\[ W(z, q) = W(e_+, e_-) = -2iz. \tag{4.95} \]

Recall that $H = H_q$ denotes the Dirchlet Schrödinger operator on $L^2(\mathbb{R}_+)$. 

### 4.4.2 Case of the real line

Consider the following differential equation on the real line $\mathbb{R}$

\[ \hat{h}[y] := -y'' + q(x)y = z^2y, \quad q \in L^1(\mathbb{R}), \quad z \in \mathbb{C}_+, \tag{4.96} \]

where the potential $q$ may be complex-valued.

The result below is likely to be well known. We provide the proof for the sake of completeness.

**Proposition 4.25.** There exists a unique pair of solutions $e_{\pm}(\cdot, z; q)$ of (4.96), known as the Jost solutions, such that $e_{\pm}(x, \cdot; q)$ are analytic on the upper half-plane $\mathbb{C}_+$,

\begin{align}
e_+(x, z; q) & = e^{ixz}(1 + o(1)), \quad e'_+(x, z; q) = ize^{ixz}(1 + o(1)), \\
e_-(x, z; q) & = e^{-ixz}(1 + o(1)), \quad e'_-(x, z; q) = -ize^{-ixz}(1 + o(1))
\end{align}

(4.97)
as $x \to +\infty$, and

\begin{align}
e_-(x, z; q) & = e^{ixz}(1 + o(1)), \quad e'_-(x, z; q) = -ize^{ixz}(1 + o(1)), \\
e_+(x, z; q) & = e^{-ixz}(1 + o(1))
\end{align}

(4.98)
as $x \to -\infty$, uniformly on compact subsets of $\mathbb{C}_+$.

$\lambda = z^2$ is the eigenvalue of the corresponding Schrödinger operator $\mathcal{H}_q$ on $L^2(\mathbb{R})$ if and only if $e_+$ and $e_-$ are proportional, that is, the Wronskian

\[ W(z, q) := e_+(0, z; q)e'_-(0, z; q) - e_-(0, z; q)e'_+(0, z; q) = 0. \]

The algebraic multiplicity $\nu(\lambda, \mathcal{H}_q)$ of the eigenvalue $\lambda = z^2$ equals the multiplicity of the corresponding zero of $W(\cdot, q)$. 

Proof. The first statement, regarding the existence and analytic properties of the Jost solutions, may be seen by extending appropriate Jost solutions on the half-line. Indeed, let \(s(x,z)\) and \(c(x,z)\) denote the solutions of (4.96) such that
\[s(0,z) = c'(0,z) = 0, \quad s'(0,z) = c(0,z) = 1.\]
We define
\[
\begin{align*}
e_+(x,z; q) &= c(x,z)e_+(0,z; q_+) + s(x,z)e'_+(0,z; q_+), \\
e_-(x,z; q) &= c(x,z)e_+(0,z; q_-) - s(x,z)e'_+(0,z; q_-),
\end{align*}
\]
where \(q_\pm\) are potentials on the half-line such that
\[q\pm(x) := q(\pm x), \quad x \in \mathbb{R}_+.\]
Notice that the functions \(e_\pm(\pm x,z; q), x \in \mathbb{R}_+\), solve the Schrödinger equations (4.93) with \(q = q_\pm\). By computing the boundary conditions of \(e_\pm(\pm x,z; q)\) at \(x = 0\), we see that
\[e_+(x,z; q) = e_+(x,z; q_+), \quad x \in \mathbb{R}_+,\]
\[e_-(x,z; q) = e_+(-x,z; q_-), \quad x \in \mathbb{R}_-.
\]
The asymptotic relations (4.97) and (4.98) follow. The analyticity statement follows from the fact that \(s(x, \cdot)\) and \(c(x, \cdot)\) are entire functions (see, for instance, [135, Lemma 5.7]) as well as the analyticity of \(e_+(0, \cdot; q_\pm)\) and \(e'_+(0, \cdot; q_\pm)\) on \(\mathbb{C}_+\).

Next, we prove the second statement, characterising the eigenvalues of \(\mathcal{H}_q\). If the Jost solutions \(e_\pm\) are proportional, the eigenfunction exists, and so \(z^2\) is the eigenvalue. Conversely, assume that \(e_+\) and \(e_-\) are linearly independent. The limit case on each half-line (cf. (4.94)) means that \(e_\pm \notin L^2(\mathbb{R}_+)\). Hence, all solutions of (4.96) from \(L^2(\mathbb{R}_+)\) are of the form \(e_\pm e_\pm\). If \(z^2 \in \sigma_d(\mathcal{H}_q)\), there is a solution \(e \in L^2(\mathbb{R})\) of (4.96) with
\[
e(x,z; q) = \begin{cases} e_+(x,z; q), & x \in \mathbb{R}_+; \\
e_-(x,z; q), & x \in \mathbb{R}_-;
\end{cases}
\]
and so \(e_+\) and \(e_-\) are proportional. A contradiction completes the proof.

The final statement follows from [93, Theorem 28].

In what follows, we shall suppress indication of \(z\) dependence where appropriate.
4.4 An integrable potential with divergent Jensen sum

Compactly supported potentials

Assume that $q$ is compactly supported, $\text{supp } q \subset [-a,a], a > 0$. Then

$$e^{-i z x}, \quad e^{-i z x}, \quad x \leq -a. \quad (4.99)$$

Also, there exist $A_{\pm}(z)$ such that

$$e_{\pm}(x, q) = A_{\pm}(z)e^{izx} + A_{\pm}(z)e^{-izx},$$

$$e'_{\pm}(x, q) = iz\left(A_{\pm}(z)e^{izx} - A_{\pm}(z)e^{-izx}\right), \quad x \leq -a. \quad (4.100)$$

We can easily calculate the Wronskian. For $x \leq -a$,

$$W(e_{\pm}, e_{\mp}) = \left(\begin{array}{c} A_{\pm}(z)e^{izx} + A_{\pm}(z)e^{-izx} \\ -iz\left(A_{\pm}(z)e^{izx} - A_{\pm}(z)e^{-izx}\right)e^{-izx} \end{array}\right) = -2izA_{\pm}(z)$$

and so

$$W(z, q) = W(e_{\pm}, e_{\mp}) = -2izA_{\pm}(z). \quad (4.101)$$

Note that equations analogous to (4.99), (4.100) and (4.101) also hold for the opposite half-line $x \geq a$.

Shifted potentials

Next, consider a shifted equation

$$h_X[y] := -y'' + q(x - X)y = z^2 y, \quad X > 0. \quad (4.102)$$

All its solutions are shifts of the corresponding solutions of (4.96). In particular, the Jost solutions satisfy

$$e_{\pm}(x, q(\cdot - X)) = e^{\pm i z X} e_{\pm}(x - X, q). \quad (4.103)$$

Symmetrisation of potentials

The following result will allow us to apply the lower bounds of Section 4.3 to even extensions of dissipative barrier potentials. We mentioned it in the introduction, see (4.30).
Proposition 4.26. Given a potential $q \in L^1(\mathbb{R}^+_+)$, let $q_e$ be its even extension on the line

$$q_e(-x) = q_e(x), \quad x \in \mathbb{R}; \quad q_e|_{\mathbb{R}^+_+} = q.$$ 

Then $\sigma_d(H_q) \subset \sigma_d(H_{q_e})$, and moreover, for each $\lambda \in \sigma_d(H_q)$,

$$\nu(\lambda, H_q) \leq \nu(\lambda, H_{q_e}). \quad (4.104)$$

Proof. It is clear from the definition, that

$$e_-(x, z; q_e) = e_+(-x, z; q_e), \quad e'_-(x, z; q_e) = -e'_+(-x, z; q_e), \quad x \in \mathbb{R}.$$ 

Hence, $W(z, q_e) = -2e_+(0, z; q_e) e'_+(0, z; q_e)$. But $q_e|_{\mathbb{R}^+_+} = q$, so

$$e_+(x, z; q_e) = e_+(x, z; q), \quad x \in \mathbb{R}^+_+; \quad W(z, q_e) = -2e_+(0, z; q) e'_+(0, z; q).$$

The result now follows from Proposition 4.25.

4.4.3 Auxiliary spectral approximation results

Large shifts

The following lemma and its corollary are crucial for the proof of Theorem 4.30. A more general, but slightly less precise, version of this result has been proven in [17, Lemma 4] by invoking the abstract notion of limiting essential spectrum (cf. [18]). In contrast to that result, it is important for us to account for algebraic multiplicities, and our proof only relies on basic ODE theory and complex analysis.

Lemma 4.27. Let $q \in L^1(\mathbb{R}^+_+)$ and $q \in L^1(\mathbb{R})$ be potentials with compact supports. For any $X > 0$, denote

$$q(x, X) := q(x) + q(x - X), \quad x \in \mathbb{R}^+_+.$$ 

Then $q(\cdot, X) \in L^1(\mathbb{R}^+_+)$ for all $X > 0$, and

$$\lim_{X \to \infty} e_+(0, z; q(\cdot, X)) = -\frac{e_+(0, z; q) W(z, q)}{2iz} = e_+(0, z; q) \frac{W(z, q)}{W(z, q)} \quad (4.105)$$

uniformly on compact subsets of $\mathbb{C}^+_+$.

Proof. Assume that

$$\text{supp } q \subset [0, b], \quad \text{supp } q \subset [-a, a], \quad a, b > 0,$$
so that \(\text{supp} q(-X) \subset [X-a, X+a]\). Assume also that \(X\) is so large that
\[
b < \frac{X}{2} := Y < X - a.
\]
Then \(\text{supp} q(-X) \subset \mathbb{R}_+\), and the supports of \(q\) and \(q(-X)\) are disjoint. For the Jost solution, we have
\[
e_+(x, q(-X)) = \begin{cases} 
  c_+ e_+(x, q) + c_- e_-(x, q), & 0 \leq x \leq Y \\
  e_+(x, q(-X)) = e^{iX} e_+(x - X, q), & x > Y,
\end{cases}
\]
for some \(c_\pm = c_\pm (X, z) \in \mathbb{C}\). The adjustment conditions at \(Y\) yield
\[
c_+ e_+(Y, q) + c_- e_-(Y, q) = e^{iX} e_+(Y, q), \\
c_+ e'_+(Y, q) + c_- e'_-(Y, q) = e^{iX} e'_+(Y, q),
\]
or, in matrix form,
\[
\begin{bmatrix} 
  e_+(Y, q) & e_-(Y, q) \\
  e'_+(Y, q) & e'_-(Y, q)
\end{bmatrix}
\begin{bmatrix} 
  c_+ \\
  c_-
\end{bmatrix}
= e^{iX}
\begin{bmatrix} 
  e_+(Y, q) \\
  e'_+(Y, q)
\end{bmatrix}.
\]
A matrix inversion yields
\[
\begin{bmatrix} 
  c_+ \\
  c_-
\end{bmatrix}
= \frac{e^{iX}}{W(z, q)}
\begin{bmatrix} 
  e'_-(Y, q) & -e_-(Y, q) \\
  -e'_+(Y, q) & e_+(Y, q)
\end{bmatrix}
\begin{bmatrix} 
  e_+(Y, q) \\
  e'_+(Y, q)
\end{bmatrix}.
\]
We can now calculate the Jost function from the upper relation in (4.106), taking into account (4.94) and (4.95)
\[
e_+(0, q(-X)) = c_+ e_+(0, q) + c_- e_-(0, q)
= -\frac{e^{iY}}{2iz}
\begin{bmatrix} 
  e_+(0, q) & e_-(0, q)
\end{bmatrix}
\begin{bmatrix} 
  -iz + o(1) & -1 + o(1) \\
  e^{iX}(-iz + o(1)) & e^{iX}(1 + o(1))
\end{bmatrix}
\begin{bmatrix} 
  e_+(Y, q) \\
  e'_+(Y, q)
\end{bmatrix}
= -\frac{e^{iY}}{2iz}
\begin{bmatrix} 
  e_+(0, q) & e_-(0, q)
\end{bmatrix}
\begin{bmatrix} 
  f_+(X, q) \\
  f'_-(X, q)
\end{bmatrix},
\]
where
\[
f_+(X, q) := (-iz + o(1)) e_+(Y, q) + (-1 + o(1)) e'_+(Y, q), \\
f_-(X, q) := e^{iX} \{(-iz + o(1)) e_+(Y, q) + (1 + o(1)) e'_+(Y, q)\}, \ Y = \frac{X}{2}.
\]
Since $Y > a$, then, by (4.100),
\[
e^{izY} f_+(X, q) = (-iz + o(1)) (A_+ + A_- e^{izX}) + (-iz + o(1)) (A_+ - A_- e^{izX})
\]
\[
= -2iz A_+ + o(1), \quad X \to \infty,
\]
uniformly on compact subsets of $\mathbb{C}_+$. It is clear from (4.100), that
\[
e^{izY} f_-(X, q) = o(1), \quad X \to \infty,
\]
also uniformly on compact subsets of $\mathbb{C}_+$. The relation (4.101) completes the proof.

Before we move on, let us clarify what we shall mean by a collection of eigenvalues. When we say that there exists a collection of $N \in \mathbb{N}$ eigenvalues $\lambda_1, \ldots, \lambda_N$ of an operator $T$, we mean that:

1. $\lambda_j$ is an eigenvalue of $T$ for each $j \in \{1, \ldots, N\}$, and
2. if $\lambda$ is repeated $\nu$ times in the collection $\lambda_1, \ldots, \lambda_N$, then $\lambda$ is an eigenvalue of $T$ with algebraic multiplicity at least $\nu$.

An integer-valued function $\nu(\cdot, T)$ is said to be an algebraic multiplicity with respect to a linear operator $T$, if $\nu(\lambda, T)$ equals the algebraic multiplicity of $\lambda$ in case when $\lambda \in \sigma_d(T)$, and $\nu(\lambda, T) = 0$ otherwise.

**Corollary 4.28.** Let the potentials $q$ and $q$ be defined as above. Given $\lambda \in \mathbb{C} \setminus \mathbb{R}_+$, put
\[
\nu = \nu(\lambda) := \nu(\lambda, H_q) + \nu(\lambda, \mathcal{H}_q).
\]
Then $\lambda \in \sigma_d(H_q) \cup \sigma_d(\mathcal{H}_q)$, if and only if there exists a collection of $\nu$ eigenvalues $\lambda_X^{(1)}, \ldots, \lambda_X^{(\nu)}$ of $H_{q(\cdot, X)}$, $X > 0$ large enough, such that
\[
\lim_{X \to \infty} \lambda_X^{(j)} = \lambda, \quad j = 1, 2, \ldots, \nu.
\]

**Proof.** By Proposition 4.25 (and similar property of the Jost function $e_+(0, \cdot, q)$), $\lambda = z^2 \in \sigma_d(H_q) \cup \sigma_d(\mathcal{H}_q)$ if and only if $z \in \mathbb{C}_+$ is a root of the right-hand side (4.105) with multiplicity equal to $\nu(\lambda)$ (4.107). The rest is a direct consequence of Lemma 4.27 and Hurwitz's theorem.

In particular, note that if $\nu(\mu, H_q) = \nu(\mu, \mathcal{H}_q) = 0$, then $\mu$ is separated from the discrete spectra $\sigma_d(H_{q(\cdot, X)})$ for all large enough $X$. 

\[\Box\]
Truncation

Given a potential \( q \in L^1(\mathbb{R}_+) \), we define its truncation at the level \( X > 0 \) as

\[
q_X(x) := \begin{cases} 
q(x), & 0 \leq x \leq X; \\
0, & x > X.
\end{cases}
\]  
(4.108)

Let \((X_n)_{n \in \mathbb{N}}\) be a sequence of positive numbers such that \( \lim_{n \to \infty} X_n = \infty \). Put

\[
q_n := q_{X_n}, \quad H_n := H_{q_n}.
\]

Lemma 4.29. In the above notation, the limit relation

\[
\lim_{X \to \infty} e^+_+(0, z; q_X) = e^+_+(0, z; q)
\]  
(4.109)

holds uniformly on compact subsets of \( \mathbb{C}_+ \). In particular, \( \lambda \in \mathbb{C} \setminus \mathbb{R}_+ \) is an eigenvalue of \( H = H_q \) of algebraic multiplicity \( \nu \) if and only if there exists a collection of eigenvalues \( \lambda_n^{(1)}, ..., \lambda_n^{(\nu)} \) of \( H_n \) such that

\[
\lim_{n \to \infty} \lambda_n^{(j)} = \lambda, \quad j = 1, 2, \ldots, \nu.
\]

Proof. The argument is similar to one above. We have

\[
e^+_+(x, q_X) = \begin{cases} 
c_+ e^+_+(x, q) + c_- e^-_-(x, q), & 0 \leq x < X; \\
ce^{izx}, & x \geq X,
\end{cases}
\]

\( c_\pm = c_\pm(X, z) \). The adjustment conditions at \( X \) yield

\[
c_+ e^+_+(X, q) + c_- e^-_-(X, q) = e^{izX},
\]
\[
c_+ e^+_+(X, q) + c_- e^-_-(X, q) = iz e^{izX},
\]
or in matrix form

\[
\begin{bmatrix}
e^+_+(X, q) & e^-_-(X, q) \n\end{bmatrix} \begin{bmatrix}
c_+ \\
c_-
\end{bmatrix} = e^{izX} \begin{bmatrix}1 \\
iz\end{bmatrix}
\]

The matrix inversion gives

\[
\begin{bmatrix}
c_+ \\
c_-
\end{bmatrix} = -\frac{e^{izX}}{2iz} \begin{bmatrix}
e^+_+(X, q) & -e^-_-(X, q) \\
-e^+_+(X, q) & e^-_-(X, q)
\end{bmatrix} \begin{bmatrix}1 \\
iz\end{bmatrix},
\]
and so
\[
c_+(X, z) = -\frac{e^{ix}}{2iz} \left[ e'_-(X, q) - iz e_-(X, q) \right],
\]
\[
c_-(X, z) = -\frac{e^{ix}}{2iz} \left[ -e'_+(X, q) + iz e_+(X, q) \right].
\]

Finally,
\[
e_+(0, q_X) = -\frac{e^{ix}}{2iz} \left\{ \left[ e'_-(X, q) - iz e_-(X, q) \right] e_+(0, q) + \left[ -e'_+(X, q) + iz e_+(X, q) \right] e_-(0, q) \right\},
\]
and (4.109) follows from the asymptotic relations (4.94).

The second statement is clear thanks to Hurwitz’s theorem. \(\square\)

### 4.4.4 Main result

We are in a position now to prove the main result of the section.

**Theorem 4.30.** There exists a potential \(q_\infty \in L^1(\mathbb{R}_+)\) with infinite Jensen sum.

**Proof.** Let \((\gamma_n)_{n \in \mathbb{N}}, (R_n)_{n \in \mathbb{N}}, (X_n)_{n \in \mathbb{N}} \subset \mathbb{R}_+,\) to be further specified. Define a sequence of Schrödinger operators on the line
\[
\mathcal{L}^\infty y := -y'' + \ell_n y, \quad \ell_n(x) := i\gamma_n \chi_{[-R_n, R_n]}(x) \in L^1(\mathbb{R}), \quad n \in \mathbb{N}. \tag{4.110}
\]

Let \((N_n)_{n \in \mathbb{N}_0}\) be defined such that \(N_0 = 0\) and, for \(n \geq 1, N_n - N_{n-1}\) equals the number of eigenvalues of \(\mathcal{L}_n\), counting algebraic multiplicity. We place all the eigenvalues \(\{\lambda_j\}_{j \in \mathbb{N}}\) of all operators \(\mathcal{L}_n\) in a single sequence in such a way that
\[
\{\lambda_{N_{n-1}+1}, \ldots, \lambda_{N_n}\} = \sigma_d(\mathcal{L}_n), \quad n \in \mathbb{N}.
\]

Define consecutively a sequence of potentials
\[
q_n(x) := q_{n-1}(x) + i\gamma_n \chi_{[X_n, X_n + 2R_n]}(x) = q_{n-1}(x) + \ell_n(x - X_n - R_n), \quad n \in \mathbb{N},
\]
\(q_0 \equiv 0,\) or, in other words,
\[
q_n(x) = \sum_{k=1}^n i\gamma_k \chi_{[X_k, X_k + 2R_k]}(x). \tag{4.111}
\]

We assume that \(X_{k+1} > X_k + 2R_k,\) so the intervals \([X_k, X_k + 2R_k], k \in \mathbb{N},\) are disjoint.
Let $M_n$ denote the cardinality of the discrete spectrum $\sigma_d(H_{q_n})$, counting algebraic multiplicity

$$\sigma_d(H_{q_n}) = \{\lambda_{j,n}\}_{j=1}^{M_n}.$$ 

In view of Corollary 4.28, we see that for large enough $X_n$,

$$M_{n-1} + N_n - N_{n-1} \leq M_n, \quad N_n - N_{n-1} \leq M_n - M_{n-1},$$

and, as $M_0 = N_0 = 0$, it follows $N_n \leq M_n$ for all $n \in \mathbb{N}$.

By Corollary 4.28, for each $n \in \mathbb{N}$, we can set $X_n$ large enough such that the collection of eigenvalues $\lambda_{j,n}$, $j = 1, \ldots, N_n$, of $H_{q_n}$ (note that $N_n \leq M_n$) satisfy

$$|\lambda_{j,n} - \lambda_j| + |\text{Im} \sqrt{\lambda_{j,n}} - \text{Im} \sqrt{\lambda_j}| \leq \frac{3}{(\pi n)^2} \text{Im} \sqrt{\lambda_j}, \quad j = N_{n-1} + 1, \ldots, N_n, \quad n \in \mathbb{N},$$

and

$$|\lambda_{j,n} - \lambda_{j,n-1}| + |\text{Im} \sqrt{\lambda_{j,n}} - \text{Im} \sqrt{\lambda_{j,n-1}}| \leq \frac{3}{(\pi n)^2} \text{Im} \sqrt{\lambda_j}, \quad j = 1, \ldots, N_{n-1}, \quad n = 2, 3, \ldots.$$ (4.112)

(4.113)

For each fixed $j \in \mathbb{N}$, $\lambda_{j,n}$ exists for all $n \geq m$, where $m \in \mathbb{N}$ is such that $\lambda_j \in \sigma_d(L_m)$. The sequence $(\lambda_{j,n})_{n \geq m}$ is Cauchy, so there exists

$$\mu_j := \lim_{n \to \infty} \lambda_{j,n}.$$ 

Next, putting $\lambda_{j,m-1} := \lambda_j$, we have for any $k \geq m + 1$

$$\sum_{n=m}^{k} \left( \text{Im} \sqrt{\lambda_{j,n}} - \text{Im} \sqrt{\lambda_{j,n-1}} \right) = \text{Im} \sqrt{\lambda_{j,k}} - \text{Im} \sqrt{\lambda_j},$$

so

$$|\text{Im} \sqrt{\lambda_{j,k}} - \text{Im} \sqrt{\lambda_j}| \leq \sum_{n=m}^{k} |\text{Im} \sqrt{\lambda_{j,n}} - \text{Im} \sqrt{\lambda_{j,n-1}}|$$

$$= \text{Im} \sqrt{\lambda_{j,m}} - \text{Im} \sqrt{\lambda_j} + \sum_{n=m+1}^{k} |\text{Im} \sqrt{\lambda_{j,n}} - \text{Im} \sqrt{\lambda_{j,n-1}}|$$

$$\leq \frac{3 \text{Im} \sqrt{\lambda_j}}{\pi^2} \sum_{n=1}^{\infty} \frac{1}{n^2} = \frac{1}{2} \text{Im} \sqrt{\lambda_j},$$
whence it follows, as $k \to \infty$, that
\[
\text{Im} \sqrt{\mu_j} \geq \frac{1}{2} \text{Im} \sqrt{\lambda_j}, \quad j \in \mathbb{N},
\]  
(4.114)

and in particular, $\mu_j \in \mathbb{C} \setminus \mathbb{R}_+$. Set
\[
\gamma_n = \frac{1}{(n \log^2(n+2))^4} < 1,
\]
\[
R_n = 1200 \gamma_n^{-3/4} = 1200 (n \log^2(n+2))^3, \quad n \in \mathbb{N},
\]
(4.115)

Define a potential on $\mathbb{R}_+$
\[
q_\infty := \sum_{n=1}^{\infty} i \gamma_n \chi_{[X_n, X_n+2R_n]}.
\]
(4.116)

Then,
\[
\|q_\infty\|_1 = 2 \sum_{n=1}^{\infty} \gamma_n R_n = 2400 \sum_{n=1}^{\infty} \frac{1}{n \log^2(n+2)} < \infty,
\]
so $q_\infty \in L^1(\mathbb{R}_+)$. The partial sums (4.111) can be viewed as truncations of $q_\infty$ at the level $X_n + 2R_n$. Lemma 4.29 implies that for each $j \in \mathbb{N}$, $\mu_j$ is an eigenvalue of $H_{q_\infty}$ with algebraic multiplicity greater than or equal to the number of times it appears in the sequence $(\mu_k)_{k \in \mathbb{N}}$. It follows that
\[
J(H_{q_\infty}) \geq \sum_{j=1}^{\infty} \text{Im} \sqrt{\mu_j} \geq \frac{1}{2} \sum_{j=1}^{\infty} \text{Im} \sqrt{\lambda_j} = \frac{1}{2} \sum_{n=1}^{\infty} J(L_n).
\]

Recall that $L_n := L_{\gamma_n, R_n}$ is defined in (4.25) as the Schrödinger operator on $L^2(\mathbb{R}_+)$ with potential $i \gamma_n \chi_{[0, R_n]}$. By Proposition 4.26, any eigenvalue of $L_n$ is also an eigenvalue of $L_{(L_n)}$ with algebraic multiplicity greater than or equal to the number of times it appears in the sequence $(\mu_k)_{k \in \mathbb{N}}$. (4.104) holds. Hence, employing the left inequality in Proposition 4.24, we have
\[
J(L_n) \geq J(L_n) \geq \frac{1}{32 \pi} \gamma_n R_n \log R_n, \quad R_n \geq 600 (\gamma_n^{3/4} + \gamma_n^{-3/4}).
\]
(4.117)

The latter inequality is true for all $n \in \mathbb{N}$ due to the choice of $R_n$ (4.115) and $\gamma_n < 1$. Consequently,
\[
J(H_{q_\infty}) \geq \frac{1}{64 \pi} \sum_{n=1}^{\infty} \gamma_n R_n \log R_n = \frac{600}{32 \pi} \sum_{n=1}^{\infty} \frac{\log R_n}{n \log^2(n+2)}.
\]
(4.118)
Since $\log R_n \sim 3 \log n$ as $n \to \infty$, the sum on the right hand side of (4.118) diverges. We conclude that the Jensen sum $J(H_{q_n}) = \infty$, completing the proof.
Chapter 5

Spectral approximation for the Laplacian on rough domains

Declaration and acknowledgements:
This chapter is joint work with Frank Rösler and appears in a similar form in the preprint [121]. We thank Victor Burenkov for his helpful comments on the Poincaré-type inequality.

5.1 Introduction

The purpose of this chapter is to investigate numerical methods for computing Dirichlet eigenvalues of bounded domains with extremely rough, possibly fractal, boundaries and to develop analytical tools for dealing with such problems. Following [14], we utilise the framework of Solvability Complexity Indices (SCI) [83] and consider sequences of arithmetic algorithms \((\Gamma_n)_{n \in \mathbb{N}}\) intended to approximate the spectrum \(\sigma(-\Delta_\mathcal{O})\) of the Dirichlet Laplacian as \(n \to \infty\) on any domain \(\mathcal{O} \subset \mathbb{R}^2\) in a specified primary set \(\Omega \subset 2^{\mathbb{R}^2}\) (recall \(2^A = \text{power set of set } A\)). The sole input to each arithmetic algorithm \(\Gamma_n\) is the information of whether or not a chosen finite number of points lie in the domain \(\mathcal{O}\) and the output is a closed subset of \(\mathbb{C}\) which should approximate \(\sigma(-\Delta_\mathcal{O})\) in an appropriate metric. Each \(\Gamma_n\) obtains its output from the input via a finite number of arithmetic operations, in a consistent way - the rigorous formulation will be given in Sections 5.2.3 and 5.2.4.

The question we ask is: what is the “largest” primary set \(\Omega\) of bounded domains we can identify such that there exists a single sequence of arithmetic algorithms computing the Dirichlet eigenvalues of any domain in \(\Omega\)?

Our first finding shows that there is no hope of constructing a single sequence of arithmetic algorithms capable of computing the Dirichlet eigenvalues of every bounded domain (cf. Proposition 5.14). The problem of proving the existence of sequences of
arithmetic algorithms that do converge is approached via explicit construction. We shall introduce an approximation \( O_n \) for a domain \( O \) which we refer to as a "pixelated domain" for \( O \) (cf. Definition 5.16). Each pixelated domain \( O_n \) is constructed solely from the information of which points in the grid \( \left( \frac{1}{n} \mathbb{Z} \right)^2 \) lie in \( O \). Utilising computable error bounds for the finite element method and matrix computations, we construct a sequence of arithmetic algorithms intended to compute the spectrum of the Dirichlet Laplacian. These arithmetic algorithms are then shown to converge on any domain for which the corresponding pixelated domains converge in the Mosco sense (cf. Definition 5.1).

The problem is thus reduced to the study of Mosco convergence, which we approach in a general way. This notion ensures convergence of Dirichlet eigenvalues and of solutions to the Poisson equation. In Section 5.4.3, we prove that if the Hausdorff convergence condition

\[
d_H(O, O_n) + d_H(\partial O, \partial O_n) \to 0 \quad \text{as} \quad n \to \infty,
\]

holds and a collection of mild geometric conditions (such as topological regularity of \( O \)) are satisfied, then \( O_n \) converges to \( O \) in the Mosco sense (cf. Theorem 5.3). This result, which is valid for arbitrary sequences of domains, is applied to pixelated domains thus concluding the identification of a large primary set \( \Omega_1 \) of bounded domains for which there exists a corresponding sequence of arithmetic algorithms (cf. Theorem 5.15). These arithmetic algorithms describe a simple numerical method that is guaranteed to converge on a very wide class of rough domains.

An intermediate step in the proof of our Mosco convergence result is the reduction of Mosco convergence \( O_n \xrightarrow{M} O \) to the establishment of a uniform Poincaré-type inequality of the form

\[
\exists C, \alpha, r_0 > 0: \forall r < r_0 : \forall u \in H^1_0(O): \quad \|u\|_{L^2(\partial rO)} \leq C \|\nabla u\|_{L^2(\partial \alpha rO)}
\]

(5.2)

where

\[
\partial' O := \{ x \in O : \text{dist}(x, \partial O) < r \},
\]

as well as an analogous sequence of inequalities verified uniformly over the sequence \( O_n \) (cf. Proposition 5.30). A Poincaré-type inequality of the form (5.2), for a single domain \( O \), is proved in Section 5.3 via a geometric method involving the construction of a bundle of paths from every point in \( \partial' O \) to \( \partial O \) (cf. Theorem 5.6). The corresponding inequalities for the sequence of domains \( O_n \) are established by combining Theorem 5.6 with a characterisation of the geometry of \( \partial O_n \) for large \( n \) (cf. Proposition 5.38).
5.1 Introduction

**Organisation of the chapter**

In Section 5.2, we state our main results and provide preliminaries. In Section 5.3, we prove an explicit Poincaré-type inequality. Section 5.4 is dedicated to proving Mosco convergence results as well as a geometric convergence result for pixelated domains. In Section 5.5, we apply our analytical results to the theory of Solvability Complexity Indices. In Section 5.6, we illustrate our results with a numerical investigation for the Dirichlet Laplacian on a filled Julia set.

**Notation and conventions**

We shall adopt the following notation, which is not necessarily standard and which will be used frequently throughout the chapter.

- For any $r > 0$ and any set $A \subseteq \mathbb{R}^d$, the $r$-collar neighbourhood $\partial^r A$ is defined (as above) by
  \[ \partial^r A := \{ x \in A : \text{dist}(x, \partial A) < r \}. \]  \hfill (5.3)

- For any set $A \subseteq \mathbb{R}^d$, we let $\#_c(A) \in \mathbb{N}_0 \cup \{\infty\}$ denote the number of connected components of $A$.

- For any $r > 0$ and any set $A \subseteq \mathbb{R}^d$, we define the set $\text{dil}_r(A)$ by
  \[ \text{dil}_r(A) := \{ x \in \mathbb{R}^d : \text{dist}(x, A) < r \}. \]  \hfill (5.4)

- $\sigma(\partial)$ shall denote the spectrum of the Dirichlet Laplacian $-\Delta_{\partial}$ on $L^2(\partial)$.

We shall also use the following notation.

- For every $A \subseteq \mathbb{R}^d$, $\mu_{\text{leb}}(A)$ denotes the $d$-dimensional Lebesgue outer measure.

- As usual, for any open set $U \subseteq \mathbb{R}^d$,
  \[ H^1(U) := \{ u \in L^2(U) : \| \nabla u \|_{L^2(U)} < \infty \}, \]
  \[ \| \cdot \|_{H^1(U)} := (\| \cdot \|_{L^2(U)}^2 + \| \nabla \cdot \|_{L^2(U)}^2)^{1/2} \]  \hfill (5.5)
  and $H^1_0(U)$ is defined as the closure of $C^\infty_c(U)$ in $H^1(U)$.

- For any non-empty, bounded sets $A, B \subseteq \mathbb{R}^d$, the Hausdorff distance between $A$ and $B$ is defined by
  \[ d_H(A, B) := \max \left\{ \sup_{x \in A} \text{dist}(x, B), \sup_{x \in B} \text{dist}(x, A) \right\}. \]  \hfill (5.6)
We define \( d_H(\emptyset, A) = \infty \) for any non-empty bounded open set \( A \subset \mathbb{R}^d \) and \( d_H(\emptyset, \emptyset) = 0 \).

- We let \( B_r(x) \subset \mathbb{R}^d \) denote an open ball of radius \( r > 0 \) about \( x \in \mathbb{R}^d \).
- The diameter of a set \( A \subset \mathbb{R}^d \) is denoted by

\[
\text{diam}(A) := \sup_{x \in A} \sup_{y \in A} |x - y| \in [0, \infty) \cup \{\infty\}. \tag{5.7}
\]

### 5.2 Preliminaries and overview of results

This section is devoted to providing preliminaries, stating our main results and reviewing some closely related literature. In Sections 5.2.1 and 5.2.2 we present our analytical results on Mosco convergence and Poincaré-type inequalities respectively. An introduction to the theory of Solvability Complexity Indices is given in Section 5.2.3 and we state our results on the computational complexity of the eigenvalue problem in Section 5.2.4.

#### 5.2.1 Mosco Convergence

The question of whether a given approximation for a domain gives a reliable spectral approximation for the Dirichlet Laplacian leads us to study Mosco convergence. We shall give the definition for \( H_0^1 \) Sobolev spaces on Euclidean domains (as in [47, Defn. 1.1]) but the notion can be more generally formulated for convex subsets of Banach spaces [106].

**Definition 5.1.** The sequence of open sets \( \mathcal{O}_n \subseteq \mathbb{R}^d, n \in \mathbb{N} \), converges to an open set \( \mathcal{O} \subseteq \mathbb{R}^d \) in the Mosco sense, denoted by \( \mathcal{O}_n \overset{M}{\to} \mathcal{O} \) as \( n \to \infty \), if:

1. Any weak limit point \( u \) of a sequence \( u_n \in H_0^1(\mathcal{O}_n), n \in \mathbb{N} \), satisfies \( u \in H_0^1(\mathcal{O}) \).
2. For every \( u \in H_0^1(\mathcal{O}) \) there exists \( u_n \in H_0^1(\mathcal{O}_n) \) such that \( u_n \to u \) as \( n \to \infty \) in \( H^1(\mathbb{R}^d) \).

Note that a function \( u \in H_0^1(\mathcal{O}) \) may be realised as a function in \( H_0^1(\mathbb{R}^d) \) via extension by zero.

For an arbitrary open set \( \mathcal{O} \subset \mathbb{R}^d \), one may realise the Dirichlet Laplacian \( -\Delta_{\mathcal{O}} \) as a positive, self-adjoint operator on \( L^2(\mathcal{O}) \) [61, Th. VI.1.4]. In the case that \( \mathcal{O} \) is bounded, the Dirichlet Laplacian has compact resolvent, hence, purely discrete spectrum.
Provided the open sets $\mathcal{O} \subset \mathbb{R}^d$ and $\mathcal{O}_n \subset \mathbb{R}^d$, $n \in \mathbb{N}$, are bounded, Mosco convergence $\mathcal{O}_n \xrightarrow{M} \mathcal{O}$ as $n \to \infty$ implies that $-\Delta_{\mathcal{O}_n}$ converges to $-\Delta_{\mathcal{O}}$ in the norm-resolvent sense as $n \to \infty$ [47, Th. 3.3 and 3.5]. In turn, norm-resolvent convergence implies spectral convergence [118, Th. VIII.23].

**Lemma 5.2.** If $\mathcal{O} \subset \mathbb{R}^d$ and $\mathcal{O}_n \subset \mathbb{R}^d$, $n \in \mathbb{N}$, are open and bounded, and $\mathcal{O}_n \xrightarrow{M} \mathcal{O}$ as $n \to \infty$, then for every bounded $S \subset \mathbb{C}$,

$$d_H(\sigma(\mathcal{O}_n) \cap S, \sigma(\mathcal{O}) \cap S) \to 0 \quad \text{as} \quad n \to \infty.$$  

An open set $\mathcal{O} \subset \mathbb{R}^d$ is said to be regular if

$$\mathcal{O} = \text{int}(\overline{\mathcal{O}}).$$  

(5.8)

For a bounded open set $\mathcal{O} \subset \mathbb{R}^d$, the quantity $Q(\partial \mathcal{O}) > 0$ is defined by

$$Q(\partial \mathcal{O}) := \inf\{\text{diam}(\Gamma) : \Gamma \subseteq \partial \mathcal{O} \text{ path-connected component of } \partial \mathcal{O}\}. \quad (5.9)$$

Recall that $\#_c$ denotes the number of connected components. Recall that a set $A \subset \mathbb{R}^d$ is locally connected if for every $x \in A$, there exists an open neighbourhood $U \subset \mathbb{R}^d$ of $x$ such that $U \cap A$ is connected. In Section 5.4.3, we shall prove the following result, which provides geometric hypotheses ensuring Mosco convergence for domains in $\mathbb{R}^2$.

**Theorem 5.3.** Suppose that $\mathcal{O} \subset \mathbb{R}^2$ is a bounded, connected, regular open set such that $\mu_{\text{leb}}(\partial \mathcal{O}) = 0$, $Q(\partial \mathcal{O}) > 0$ and $\#_c(\text{int}(\mathcal{O}^c)) = \#_c(\mathcal{O}^c) < \infty$. Suppose that $\mathcal{O}_n \subset \mathbb{R}^2$, $n \in \mathbb{N}$, is a collection of bounded, open sets such that $\partial \mathcal{O}_n$ is locally connected for all $n \in \mathbb{N}$ and such that

$$d_H(\mathcal{O}_n) + d_H(\partial \mathcal{O}_n, \partial \mathcal{O}) \to 0 \quad \text{as} \quad n \to \infty. \quad (5.10)$$

Then, $\mathcal{O}_n$ converges to $\mathcal{O}$ in the Mosco sense as $n \to \infty$.

The condition $Q(\partial \mathcal{O}) > 0$ in the above theorem can be replaced by the condition that each connected component of $\partial \mathcal{O}$ is path-connected (cf. Remark 5.40). In turn, the latter condition satisfied if $\partial \mathcal{O}$ is locally connected [105, §16]. A sufficient condition for the hypothesis $\mu_{\text{leb}}(\partial \mathcal{O}) = 0$ is $\text{dim}_H(\partial \mathcal{O}) < 2$ where $\text{dim}_H$ denotes the Hausdorff dimension [64]. The condition $\#_c(\text{int}(\mathcal{O})^c) = \#_c(\mathcal{O}^c) < \infty$ intuitively states that $\mathcal{O}$ has a finite number of holes, which neither touch each other nor the outer boundary component of the domain.
Examples

The following classes of domains satisfy the hypotheses of Theorem 5.3. The first example includes the classical Koch snowflake domain. One could also modify this example to allow for domains with holes.

Example 5.4 (Interior of a Jordan curve). Let \( C \subset \mathbb{R}^2 \) be any Jordan curve with \( \mu_{\text{leb}}(C) = 0 \). By the Jordan curve theorem, \( \mathbb{R}^2 \setminus C \) is a disjoint union of two open, connected sets - a bounded interior \( \Theta \) and an unbounded exterior \( S_{\text{ext}} \). Then, \( \Theta \) satisfies the hypotheses of Theorem 5.3.

Proof. It is known that \( \partial \Theta = C \), hence it holds that \( \mu_{\text{leb}}(\partial \Theta) = 0 \) and \( Q(\partial \Theta) > 0 \). It is also known that \( \partial(S_{\text{ext}}) = C \), hence any open set \( U \subset \mathbb{R}^2 \) satisfies either \( U \subset \Theta \) or \( U \cap S_{\text{ext}} \neq \emptyset \). From this it follows that \( \text{int}(\Theta) = \Theta \), that is, \( \Theta \) is regular. Similarly, we have that \( \text{int}(\Theta^c) = S_{\text{ext}} \) so \( \#_c(\text{int}(\Theta^c)) = \#_c(\Theta^c) = 1 \).

The second example is a concrete special case of the above class of domains and is the object study in a numerical investigation in Section 5.6. We naturally identify \( \mathbb{C} \cong \mathbb{R}^2 \).

Example 5.5 (Filled Julia sets with connected interior). Let \( f_c(z) := z^2 + c \), where \( c \in \mathbb{C} \) satisfies \( |c| < \frac{1}{4} \). Consider the filled Julia set

\[
K(f_c) := \{ z \in \mathbb{C} : (f_c^{\circ n}(z))_{n \in \mathbb{N}} \text{ bounded} \}
\]

where \( f^{\circ n}(z) := \underbrace{f \circ \cdots \circ f}(z) \). The domain \( \Theta = \text{int}(K(f_c)) \) satisfies the hypotheses of Theorem 5.3.

Proof. Firstly, \( K(f_c) \) is compact and \( \partial \Theta = \partial K(f_c) = J(f_c) \), where \( J(f_c) \) is the so-called Julia set for \( f_c \) [105, Lem. 17.1]. The Julia set can be thought of as the set of \( z \in \mathbb{C} \) for which the dynamics of \( f^{\circ n}(z) \) is chaotic. Since \( |c| < \frac{1}{4} \), it is known that \( J(f_c) \) is a Jordan curve [64, Th. 14.16]. By Example 5.4, it suffices that \( \mu_{\text{leb}}(J(f_c)) = 0 \).

One may show that \( B_{1/4}(0) \subset K(f_c) \) [64, Ex. 14.3], hence, \( |f_c'(z)| > 0 \) for every \( z \in J(f_c) \), that is, there are no critical points on the Julia set. It turns out that this is enough to ensure that the Lebesgue measure of the Julia set vanishes (cf. [31, pg. 2] and references therein).

On the other hand, consider the Mandelbrot set

\[
M := \{ c \in \mathbb{C} : (f_c^{\circ n}(0))_{n \in \mathbb{N}} \text{ bounded} \}.
\]
Then, the domains \( O = \text{int}(M) \) and \( O = B_X(0) \setminus M \) (where \( X > \text{diam}(M) \)) do not satisfy the hypotheses of Theorem 5.3, since \( \# \text{int}(M) = \infty \). The questions of whether \( \mu_{eb}(\partial M) = 0 \) and \( \partial M \) is path connected are major open problems, the latter being implied by the famous MLC conjecture (MLC = Mandelbrot set locally connected) [56].

**Comparison to known results**

Let us now discuss some related results in the literature. Firstly, it is known that nested approximations converge in the Mosco sense, that is, for \( O \subseteq \mathbb{R}^d \) and \( O_n \subseteq \mathbb{R}^d, n \in \mathbb{N} \), open we have [48, Prop. 5.4.1]

\[
\forall n \in \mathbb{N} : O_n \subseteq O_{n+1} \subseteq O \quad \text{and} \quad O = \bigcup_{n=1}^{\infty} O_n \quad \Rightarrow \quad O_n \xrightarrow{M} O \quad \text{as} \quad n \to \infty.
\]

For non-nested approximations, such as those we consider in our study of the computational eigenvalue problem, Mosco convergence is more difficult to prove.

An open set \( O \subset \mathbb{R}^d \) is said to be **stable** if [48, Defn. 5.4.1]

\[
H^1_0(O) = H^1_0(\overline{O}) := \{ u|_O : u \in H^1(\mathbb{R}^d), u = 0 \text{ a.e. on } O \}.
\]

This notion allows for the application of powerful spectral and Mosco convergence results [117, 47, 46]. In particular, if a sequence of bounded domains \( O_n \subset \mathbb{R}^d \) converges to a bounded, stable domain \( O \subset \mathbb{R}^d \) in the sense that there exists “inner” and “outer” domains \( O'_n \subset \mathbb{R}^d, n \in \mathbb{N} \), and \( O'^+_n \subset \mathbb{R}^d, n \in \mathbb{N} \), such that for all \( n \in \mathbb{N} \),

\[
O'_n \subseteq O_n \subseteq O'^+_n,
\]

\[
O'_n \subseteq O'_{n+1} \subseteq O, \quad \bigcup_{k=1}^{\infty} O'_k = O
\]

and

\[
O \subseteq O'^+_n \subseteq O'^+_n, \quad \bigcap_{k=1}^{\infty} O'^+_k \subseteq \overline{O},
\]

then \( O_n \xrightarrow{M} O \) as \( n \to \infty \).

Stability may be characterised in terms of stability of the Dirichlet problems [5] and in terms of capacities [47][2, Ch. 11]. A sufficient geometric condition that ensures that a domain is stable is that it is bounded and the boundary is locally the

\[1\]

Indeed, we have \( O'_n \xrightarrow{M} O \) by [48, Prop. 5.4.1] and \( O'^+_n \xrightarrow{M} O \) by [48, Prop 5.4.4]. Then, by the “sandwich” lemma [36, Lemma 2.3], it follows that \( O_n \xrightarrow{M} O \).
image of a continuous map [5, Prop. 2.2]. Another sufficient condition, which allows for certain domains with fractal boundaries has been proven in [33] and is discussed below.

Spectral convergence results, with convergence rates, have also been obtained for the Laplacian on Reifenberg-flat domains [95] and for more general non-negative, elliptic, self-adjoint operators [49, 32]. As far as we are aware these results are not applicable to non-nested approximations of domains with fractal boundary.

Recently, domains with fractal boundaries have also been studied. In [33, Corollary 4.13], the authors proved that E-thick domains \( \mathcal{O} \) with \( \mu_{\text{leb}}(\partial \mathcal{O}) = 0 \) are stable. Furthermore, in [85, Theorem 8], the authors proved a related type of Mosco convergence result for quadratic functionals on \((\varepsilon, \infty)\)-domains. Note that there exist domains satisfying the hypotheses of Theorem 5.3 that are neither E-thick, nor \((\varepsilon, \infty)\)-domains, for instance, domains with reentrant cusps like the interior of a standard cardioid (see [136, Figure 3.3 and Remark 3.7] for an illustration and discussion of such cusps). Also, for \( \mathcal{O} \) to be an \((\varepsilon, \infty)\)-domain, it is necessary and sufficient that \( \partial \mathcal{O} \) is a quasi-circle, that is, the corresponding map \( \iota: S^1 \to \mathbb{R}^2 \) (such that \( \iota(S^1) = \partial \mathcal{O} \)) is the restriction of a quasi-conformal map [87, Theorem C].

### 5.2.2 An explicit Poincaré-type Inequality

A key ingredient for the proof of Theorem 5.3 is a Poincaré-type inequality for collar neighbourhoods of the boundary of a domain. Theorem 5.6 provides a bound with an explicit constant which is independent of the particular domain \( \mathcal{O} \). As far as the authors are aware, this is the first Poincaré-type inequality of its form to be reported. The proof is given in Section 5.3.4. Recall that \( Q(\partial \mathcal{O}) \) is defined by (5.9).

**Theorem 5.6.** Let \( \mathcal{O} \subseteq \mathbb{R}^2 \) be any open set. If \( Q(\partial \mathcal{O}) > 0 \) and \( r > 0 \) satisfies \( 4\sqrt{2}r < Q(\partial \mathcal{O}) \), then

\[
\|u\|_{L^2(\partial \mathcal{O})} \leq 5r \|\nabla u\|_{L^2(\partial^2 \sqrt{2} \mathcal{O})}
\]  

for all \( u \in H^1_0(\mathcal{O}) \).

**Comparison to known results**

Precise bounds have recently been obtained in terms of Hardy inequalities (see [8, 9, 88, 27, 137] and the references therein). These are bounds on the \( L^p \) norm of \( u/\eta \) in terms of \( \nabla u \), where \( u \in W^{1,p}_0(\mathcal{O}) \) and \( \eta(x) = \text{dist}(x, \partial \mathcal{O}) \). Classically, the domain \( \mathcal{O} \) is assumed to be of class \( C^1 \), but relaxations are possible (see [8, 137] for an overview). Hardy-type inequalities have also been studied in connection with questions of spectral convergence [49].
We mention the following result from [88][137, Th. 3.4.8].

If \(d \geq 2\) and \(\mathcal{O} \subset \mathbb{R}^d\) is open, connected, such that \(\mathbb{R}^d \setminus \mathcal{O}\) is connected and unbounded, then there exists \(C > 0\) such that for all \(u \in W_0^{1,d}(\mathcal{O})\)

\[
\left\| \frac{u}{\eta} \right\|_{L^d(\mathcal{O})} \leq C \left\| \nabla u \right\|_{L^d(\mathcal{O})}.
\] (5.14)

The connectedness assumption on \(\mathbb{R}^d \setminus \mathcal{O}\) can be replaced by the weaker, technical condition of so-called uniform \(m\)-fatness (cf. [88, Th. 4.1]) Applying inequality (5.14) to the case \(d = 2\) immediately yields the bound \(\|u\|_{L^2(\partial r \mathcal{O})} \leq Cr\|\nabla u\|_{L^2(\mathcal{O})}\) for a \(r\)-collar neighbourhood of \(\partial \mathcal{O}\). Note that this statement is weaker than Theorem 5.6 in two ways: first, the constant \(C\) is neither explicit, nor independent of \(\mathcal{O}\) and second, the \(L^2\)-norm of \(\nabla u\) is over the entire domain \(\mathcal{O}\), rather than a neighbourhood of \(\partial \mathcal{O}\). These differences are key for application to our proof of Theorem 5.3.

5.2.3 Computational problems and arithmetic algorithms

The theory of the Solvability Complexity Index (SCI) hierarchy was developed in [11, 83, 12]. Broadly speaking, it studies the question Given a class \(\Omega\) of computational problems, can the solutions always be computed by an algorithm? In order to give a rigorous formulation of this question, it is necessary to introduce precise definitions of the terms “computational problem” and “algorithm” (the reader may think of a Turing machine for the time being). We will give a brief review of the central elements of the theory here and refer to [11] for further details.

**Definition 5.7** (Computational problem). A computational problem is a quadruple \((\Omega, \Lambda, \mathcal{M}, \Xi)\), where

\(\text{(A)}\) \(\Omega\) is a set, called the primary set,

\(\text{(B)}\) \(\Lambda\) is a set of complex-valued functions on \(\Omega\), called the evaluation set,

\(\text{(C)}\) \(\mathcal{M}\) is a metric space,

\(\text{(D)}\) \(\Xi : \Omega \rightarrow \mathcal{M}\) is a map, called the problem function.

Intuitively, elements of the primary set \(\Omega\) are the objects giving rise to the computational problems, the evaluation set \(\Lambda\) represents the information available to an algorithm, the metric space \(\mathcal{M}\) is the output of an algorithm and the problem function \(\Xi\) represents the true solutions of the computational problems.
Example 5.8. An instructive example of a computational problem in the sense of Definition 5.7 is given by the following data. Let $\Omega = B(\ell^2(\mathbb{N}))$, the bounded operators on the space of square summable sequences, $\Lambda = \{ A \mapsto \langle Ae_i, e_j \rangle_{\ell^2} : i, j \in \mathbb{N} \}$ the set of matrix elements in the canonical basis, $\mathcal{M} = \{ \text{comp}(\mathbb{C}), d_H \}$ the compact subsets of $\mathbb{C}$, together with the Hausdorff distance $d_H$, and finally $\Xi(A) = \sigma(A)$, the spectrum of an operator. In words, this computational problem reads “Compute the spectrum of a bounded operator on $\ell^2(\mathbb{N})$ using its matrix entries as an input.”

Now we are in position to define the notion of an arithmetic algorithm. The definition here differs slightly from the one in [11, Definition 6.3] as it is convenient for us to explicitly indicate the evaluation set $\Lambda$.

Definition 5.9 (Arithmetic algorithm). Let $(\Omega, \Lambda, \mathcal{M}, \Xi)$ be a computational problem. An arithmetic algorithm with input $\Lambda$ is a map $\Gamma : \Omega \to \mathcal{M}$ such that for each $T \in \Omega$ there exists a finite subset $\Lambda_\Gamma(T) \subset \Lambda$ such that

(i) the action of $\Gamma$ on $T$ depends only on $\{ f(T) \}_{f \in \Lambda_\Gamma(T)}$,

(ii) (consistency) for every $S \in \Omega$ with $f(T) = f(S)$ for all $f \in \Lambda_\Gamma(T)$ one has $\Lambda_\Gamma(S) = \Lambda_\Gamma(T)$,

(iii) the action of $\Gamma$ on $T$ consists of performing only finitely many arithmetic operations$^2$ on $\{ f(T) \}_{f \in \Lambda_\Gamma(T)}$.

Arithmetic algorithms give a notion of computability. We shall deem a computational problem $(\Omega, \Lambda, \mathcal{M}, \Xi)$ to be computable if

$$\exists \text{ arithmetic algorithms } \left\{ \Gamma_n : \Omega \to \mathcal{M}, n \in \mathbb{N} \right\} \text{ with input } \Lambda \text{ s.t. } \lim_{n \to \infty} d_{\mathcal{M}}(\Gamma_n(T), \Xi(T)) = 0 \forall T \in \Omega,$$

(5.15)

where $d_{\mathcal{M}}$ denote the metric for the metric space $\mathcal{M}$.

Example 5.10 (Example 5.8 continued). The solvability of the computational problem defined in Example 5.8 is thus equivalent to the existence of a sequence of arithmetic algorithms $(\Gamma_n)_{n \in \mathbb{N}}$, where $\Gamma_n : B(\ell^2(\mathbb{N})) \to \text{comp}(\mathbb{C})$ such that (i)-(iii) of Definition 5.9 are satisfied and $d_H(\Gamma_n(A), \sigma(A)) \to 0$ as $n \to \infty$ for all $A \in B(\ell^2(\mathbb{N}))$. In particular, for each fixed $n \in \mathbb{N}$, the image $\Gamma_n(A)$ must be computable from finitely many matrix elements of $A$ in finitely many arithmetic operations.

$^2$Recall that the arithmetic operations are $+, -, \times, \div$, as well as exponentiation and complex conjugation. Arithmetic comparisons are also allowed, that is, given $a, b \in \mathbb{R}$ we may test whether $a < b$, $b > a$ or $a = b$. A more precise (but less transparent) definition may also be given in terms of BSS machines [15][12, Definition 6.6].
In [83], Hansen showed that it is possible to compute \( \sigma(A) \) for \( A \in \mathcal{B}(\ell^2(\mathbb{N})) \) as above. However, rather than having algorithms \( \Gamma_n \) with a single index \( n \in \mathbb{N} \), three indices were required, satisfying \( \sigma(A) = \lim_{n_3 \to \infty} \lim_{n_2 \to \infty} \lim_{n_1 \to \infty} \Gamma_{n_1,n_2,n_3}(A) \). The algorithms \( \Gamma_{n_1,n_2,n_3} \) are given explicitly, and can be implemented numerically. In [11] it was proved that this is optimal: this computation cannot be performed with fewer than 3 limits, and hence we say that this problem has an SCI value of 3.

We formalise the foregoing example with the following definitions:

**Definition 5.11 (Tower of arithmetic algorithms).** Let \((\Omega, \Lambda, \mathcal{M}, \Xi)\) be a computational problem. A tower of algorithms of height \( k \) for \( \Xi \) is a family

\[
\{ \Gamma_{n_1,n_2,...,n_k} : \Omega \to \mathcal{M} | n_j \in \mathbb{N}, j = 1,...,k \}
\]

of arithmetic algorithms such that for all \( T \in \Omega \)

\[
\Xi(T) = \lim_{n_k \to \infty} \cdots \lim_{n_1 \to \infty} \Gamma_{n_1,n_2,...,n_k}(T).
\]

**Definition 5.12 (SCI).** A computational problem \((\Omega, \Lambda, \mathcal{M}, \Xi)\) is said to have a Solvability Complexity Index (SCI) of \( k \) if \( k \) is the smallest integer for which there exists a tower of algorithms of height \( k \) for \( \Xi \). If a computational problem has solvability complexity index \( k \), we write

\[
\text{SCI}(\Omega, \Lambda, \mathcal{M}, \Xi) = k.
\]

With this new terminology, condition (5.15) is equivalent to \( \text{SCI}(\Omega, \Lambda, \mathcal{M}, \Xi) = 1 \).

Definition 5.12 naturally places computational problems into a hierarchy: the higher the SCI of a problem, the more limits are needed to solve it, thus the higher its computational complexity.

A refinement of the SCI hierarchy (as described above) has been proposed in [11] based on whether \( \Gamma_n \) approximates \( \Xi \) from above or from below (in an appropriate sense) and whether explicit error control is possible. We shall not dive any deeper into these refinements here and refer the interested reader to [11, Def. 6.11].

Several kinds of computational (spectral and other) problems have been classified in the SCI hierarchy in recent years, not just in the abstract bounded setting of Example 5.8, but also in more applied PDE problems. Recent results include classification of abstract spectral problems [11, 40], spectral problems for PDE on \( \mathbb{R}^d \) [11, 41, 42, 120], resonance problems for potential scattering [13] and obstacle scattering [14]. The computability of spectral problems on domains in \( \mathbb{R}^d \) and its relation to boundary regularity has not yet been studied as far as the authors are aware.
### 5.2.4 Computational eigenvalue problem for the Laplacian

Now we describe our contribution to the SCI hierarchy.

**Statement of SCI results**

We shall consider the following computational problem.

(A) The primary set $\Omega$ is a subset of the set of domains

$$\Omega_0 := \{ \emptyset \subset \mathbb{R}^2 : \emptyset \text{ open, bounded and connected} \}.$$  

(B) The evaluation set is

$$\Lambda_0 := \{ \emptyset \mapsto \chi_{\emptyset}(x) : x \in \mathbb{R}^2 \}$$

where $\chi$ is the characteristic function.

(C) The metric space is $\mathcal{M} := (\text{cl}(\mathbb{C}), d_{\text{AW}})$, where $\text{cl}(\mathbb{C})$ denotes the set of closed, nonempty subsets of $\mathbb{C}$ and $d_{\text{AW}}$ denotes the Attouch-Wets metric. Note that the spectrum of the Dirichlet Laplacian on a bounded domain is always closed and nonempty by classical results. Recall that the Attouch-Wets metric is defined by

$$d_{\text{AW}}(A, B) := \sum_{j=1}^{\infty} 2^{-j} \min \left\{ 1, \sup_{|x| \leq j} |\text{dist}(x, A) - \text{dist}(x, B)| \right\}$$

for any subsets $\emptyset \neq A, B \subseteq \mathbb{C}$ (cf. [10, Ch. 3]). Note that for bounded sets $A, B \subseteq \mathbb{C}$, $d_{\text{AW}}$ is equivalent to the Haussdorff distance $d_{H}$ [10, Th. 3.2.3].

(D) The problem function $\Xi_{\sigma} : \Omega \to \mathcal{M}$ is defined by $\Xi_{\sigma}(\emptyset) := \sigma(\emptyset)$, where recall that $\sigma(\emptyset)$ denotes the spectrum of the Dirichlet Laplacian $-\Delta_{\emptyset}$ on $L^2(\emptyset)$.

**Remark 5.13.** In addition to $\Lambda_0$ we shall always assume that the $n^{th}$ arithmetic algorithm $\Gamma_n(\emptyset)$ has access to the information that it is the $n^{th}$ in the sequence, i.e., the map $\emptyset \mapsto n$ is also in the evaluation set. For notational brevity, we do not explicitly indicate this.

The following result follows immediately from Proposition 5.48. The proof is based on the construction of a certain counter-example which “fools” a sequence of arithmetic algorithms aiming to compute the spectrum on an arbitrary domain in $\Omega_0$.  

5.2 Preliminaries and overview of results

**Proposition 5.14.** There does not exist a sequence of arithmetic algorithms \( \Gamma_n : \Omega_0 \to \text{cl}(\mathbb{C}) \) with input \( \Lambda_0 \) which satisfy

\[
d_{AW}(\Gamma_n(\mathcal{O}), \sigma(\mathcal{O})) \to 0 \quad \text{as} \quad n \to \infty \quad \text{for all} \quad \mathcal{O} \in \Omega_0.
\]

That is,

\[
\text{SCI}(\Omega_0, \Lambda_0, \mathcal{M}, \Xi_\sigma) \geq 2.
\]

Our final result is an explicit construction of a sequence of arithmetic algorithms, describing a simple numerical method for the computation of eigenvalues of the Dirichlet Laplacian on a large class of bounded domains. Recall that \( Q(\partial \mathcal{O}) \) is defined by (5.9) and \( \#_c \) is the number of connected components.

**Theorem 5.15.** Let

\[
\Omega_1 := \left\{ \mathcal{O} \in \Omega_0 : \mathcal{O} = \text{int}(\overline{\mathcal{O}}), \mu_{\text{leb}}(\partial \mathcal{O}) = 0, Q(\partial \mathcal{O}) > 0, \text{ and } \#_c(\text{int}(\mathcal{O}^c)) = \#_c(\mathcal{O}^c) < \infty \right\}. \tag{5.16}
\]

There exists a sequence of arithmetic algorithms \( \Gamma_n : \Omega_1 \to \text{cl}(\mathbb{C}) \) with input \( \Lambda_0 \) such that

\[
d_{AW}(\Gamma_n(\mathcal{O}), \sigma(\mathcal{O})) \to 0 \quad \text{as} \quad n \to \infty \quad \text{for all} \quad \mathcal{O} \in \Omega_1,
\]

that is,

\[
\text{SCI}(\Omega_1, \Lambda_0, \mathcal{M}, \Xi_\sigma) = 1.
\]

Note that any domain described in Example 5.4 or 5.5 lies in \( \Omega_1 \).

The arithmetic algorithms in the above theorem are based on the following approximation for a Euclidean domain.

**Definition 5.16.** For any open set \( \mathcal{O} \subseteq \mathbb{R}^d \), the pixelated domains for \( \mathcal{O} \) are the open sets \( \mathcal{O}_n \subseteq \mathbb{R}^d, n \in \mathbb{N} \), defined by

\[
\mathcal{O}_n := \text{int}\left( \bigcup_{j \in \mathbb{Z}^d} (j + [-\frac{1}{2n}, \frac{1}{2n}]^d) \right),
\]
Spectral approximation for the Laplacian on rough domains

\[ L_n := \left\{ j \in \mathbb{Z}_n^d : j \in \Omega \right\} \quad \text{and} \quad \mathbb{Z}_n^d := (n^{-1}\mathbb{Z})^d. \]

The basic idea behind the construction of the algorithm is to combine pixelation approximations of the domain with computable error bounds for the finite-element method and matrix eigenvalue problem. The algorithm of Theorem 5.15 can be summarised as:

**Step 1** Approximate \( \Omega \) by a corresponding pixelated domain \( \Omega_n \).

**Step 2** Approximate the eigenvalues of \( \Omega_n \) to an error \( \frac{1}{n} \) (in the Attouch-Wets metric) by the eigenvalues of a matrix pencil, using computable error bounds for the finite element method on a uniform triangulation of \( \Omega_n \).

**Step 3** Compute the eigenvalues of the matrix pencil to an error \( \frac{1}{n} \) (in the Attouch-Wets metric) using the Jacobi method combined with a-posteriori error bounds for the associated matrix pencils.

The computable error bounds for the finite element method that we employ are those of Liu and Oishi [100], but similar bounds have also been obtained in [34, 35]. The matrix pencil a-posteriori estimates we utilise are due to Oishi [111].

In Proposition 5.46, this algorithm is shown to converge on any bounded domains for which the pixelation approximations converge in the Mosco sense, that is, for any domain in

\[ \Omega_M := \left\{ \Omega \subset \mathbb{R}^2 : \Omega \text{ open, bounded and } \Omega_n \xrightarrow{M} \Omega \text{ where } \Omega_n \text{ pixelated domains for } \Omega \right\}. \]

In Proposition 5.42, we show that if \( \Omega_n \) are the pixelated domains for a bounded, open set \( \Omega \subset \mathbb{R}^d \) satisfying \( \bar{\Omega} = \text{int}(\Omega) \) and \( \mu_{\text{leb}}(\partial \Omega) = 0 \), then

\[ d_H(\Omega_n, \bar{\Omega}) + d_H(\partial \Omega_n, \partial \bar{\Omega}) \to 0 \quad \text{as} \quad n \to \infty. \]

Theorem 5.15 therefore follows by an application of our Mosco convergence result Theorem 5.3.

**Remark 5.17.** We believe that use of computable error bounds in Step 2 may not be strictly necessary. As mentioned, Mosco convergence can also be defined for more general Hilbert spaces. In particular, we can makes sense of statements like \( V_0(\Omega_n) \xrightarrow{M} H^1(\bar{\Omega}) \) as \( n \to \infty \), where \( V_0(\Omega_n) \) is a P1 finite element space corresponding to a triangulation of \( \Omega_n \). Such techniques have application to finding conditions under which finite element error may be linked with geometric approximation error [36].
5.3 An explicit Poincaré-type inequality

This section is devoted to the proof of the Poincaré-type inequality Theorem 5.6 on the collar neighbourhood $\partial^r \mathcal{O}$ of a domain $\mathcal{O} \subset \mathbb{R}^2$. Our approach is inspired by the simple proof of the Poincaré inequality in the textbook of Adams and the Fournier [3, Theorem 6.30]. The method consists in expressing the value of a function in $H_0^1(\mathcal{O})$ at a given point $x \in \partial^r \mathcal{O}$ as an integral over a path from $x$ to the boundary $\partial \mathcal{O}$. We shall explicitly construct these paths. This must be done in a way such that the bundle of paths corresponding to the different points in $\partial^r \mathcal{O}$ do not “concentrate” too much at any given point on the boundary. This is made possible by the assumption $Q(\partial \mathcal{O}) > 0$ (cf. (5.9)). In fact, this assumption is necessary, as the following example shows.

**Example 5.18.** Let $1 > \varepsilon > 0$ and consider the domain $\mathcal{O} := B_1(0) \setminus B_\varepsilon(0) \subset \mathbb{R}^2$ (hence $Q(\partial \mathcal{O}) = 2\varepsilon$). In polar coordinates, define the function $f_\varepsilon(r) = \frac{\log(\varepsilon) - \log(r)}{\log(\varepsilon)}$.

An explicit calculation shows

$$
\|f_\varepsilon\|_{L^2(\mathcal{O})}^2 = 2\pi \left( \frac{1}{2} + \frac{1}{2\log(\varepsilon)} + \frac{1 - \varepsilon^2}{4\log^2(\varepsilon)} \right)
$$

$$
\|\nabla f_\varepsilon\|_{L^2(\mathcal{O})}^2 = -\frac{2\pi}{\log(\varepsilon)}
$$

And thus

$$
\frac{\|f_\varepsilon\|_{L^2(\mathcal{O})}^2}{\|\nabla f_\varepsilon\|_{L^2(\mathcal{O})}^2} \geq C|\log(\varepsilon)|
$$

as $\varepsilon \to 0$. Since $f_\varepsilon(x) \to 1$ as $x \to \partial B_1(0)$, $f$ can be extended to a $H^1_0$ function on any domain that contains $\overline{B_1(0)} \setminus B_\varepsilon(0)$. This example shows that no uniform Poincaré inequality can hold on domains with arbitrarily small holes. Similar statements can be proved in higher dimensions (cf. [117, Lemma 4.5]).

Throughout the section, let $\mathcal{O} \subset \mathbb{R}^2$ be an arbitrary open set and fix the value $r > 0$, corresponding to the size of the collar neighbourhood $\partial^r \mathcal{O}$.

5.3.1 Some geometric notions

The construction of the bundle of paths shall be assisted by the introduction of a grid of boxes covering $\mathbb{R}^2$. We choose the boxes to have edge of length $r > 0$ - exactly the size of the collar neighbourhood $\partial^r \mathcal{O}$. We shall introduce, for the purpose of the proof, various notions such as cell-paths, g-cells and lg-cells. Cell-paths can be thought of a higher level structure within which the bundles of paths shall be constructed. Then,
g-cells and lg-cells (good cells and long good cells) are cells which \( \partial \Theta \) intersects in a way such that a bundle of paths can be terminated at that cell.

**Definition 5.19.** (a) A **cell** is a closed box \( j + [0,r]^2 \) for some \( j \in (r \mathbb{Z})^2 \).

(b) An **edge** of a cell is one of the 4 connected, closed straight line segments whose union comprises the boundary of the cell.

**Definition 5.20.** A **g-cell** is a cell \( c_0 \) such that two distinct, parallel edges \( e_1 \) and \( e_2 \) of \( c_0 \) are connected by a path-connected segment of \( \partial \Theta \) in \( c_0 \), that is,

\[
\exists \Gamma \subseteq \partial \Theta \cap c_0 : \Gamma \text{ path-connected}, \Gamma \cap e_1 \neq \emptyset \text{ and } \Gamma \cap e_2 \neq \emptyset.
\]

The two edges of \( c_0 \) other than \( e_1 \) and \( e_2 \) are called the **normal edges**.

**Definition 5.21.** (a) A **long-cell** is a set of two cells \( \{c_1, c_2\} \) such that \( c_1 \) and \( c_2 \) share a common edge.

(b) An **edge** of a long-cell \( \{c_1, c_2\} \) is one of the 4 connected, closed straight line segments whose union comprises the boundary of the set \( c_1 \cup c_2 \).

(c) A **short-edge** of the long-cell is an edge of the long cell which is also the edge of a cell.

(d) A **long-edge** of a long-cell is an edge of the long-cell which is not a short-edge.

**Definition 5.22.** An **lg-cell** is a long cell \( \{c_1, c_2\} \) for which there exist distinct long-edges \( e_1 \) and \( e_2 \) connected by a path-connected segment of \( \partial \Theta \) in \( c_0 \), that is,

\[
\exists \Gamma \subseteq \partial \Theta \cap (c_1 \cup c_2) : \Gamma \text{ path-connected}, \Gamma \cap e_1 \neq \emptyset \text{ and } \Gamma \cap e_2 \neq \emptyset.
\]

The **normal edges** of a lg-cell refers to its short edges. We shall often say that an lg-cell \( \{c_1, c_2\} \) is contained in a set \( A \) to mean that \( c_1 \cup c_2 \subseteq A \).

**Definition 5.23.** A **cell path** from a cell \( c_0 \) to a g-cell \( c_n \) (or to an lg-cell \( \{c_n, c_{n+1}\} \)) is a sequence of cells \( (c_1, \ldots, c_{n-1}) \) such that

1. if \( n \geq 2 \), then \( c_j \) shares a common edge with \( c_{j-1} \) for each \( j \in \{1, \ldots, n-1\} \),

2. if \( n \geq 1 \), then there exists an edge of \( c_{n-1} \) which is also a normal edge of the g-cell \( c_n \) (or of the lg-cell \( \{c_n, c_{n+1}\} \) resp.) and

3. \( (c_0, \ldots, c_n) \) (or \( (c_0, \ldots, c_{n+1}) \) resp.) consists of distinct elements.
5.3 An explicit Poincaré-type inequality

Figure 5.2 Illustration for Definitions 5.20 and 5.22.

Here, we allow the possibility that \( n = 1 \), corresponding to the case that there exists an edge of \( c_0 \) which is also a normal edge of the g-cell \( c_n \) (or of the lg-cell \( \{c_n, c_{n+1}\} \) resp.) and we allow the possibility that \( n = 0 \), corresponding to the case that \( c_0 \) is itself a g-cell (or in an lg-cell resp.). In both of these cases, the cell-path is empty.

**Definition 5.24.** (a) The *1-cell neighbourhood* \( D_1[c_0] \) of a cell \( c_0 \) is the union of all cells sharing an edge or a corner with \( c_0 \), that is,

\[
D_1[c_0] = \bigcup \{c : c \text{ is a cell and } c \cap c_0 \neq \emptyset\}.
\]

(b) The *2-cell neighbourhood* \( D_2[c_0] \) of a cell \( c_0 \) is the union of all cells sharing an edge or a corner with \( D_1[c_0] \), that is,

\[
D_2[c_0] = \bigcup \{c : c \text{ is a cell and } c \cap D_1[c_0] \neq \emptyset\}.
\]

**Definition 5.25.** (a) A *filled cell* is a cell \( c \) such that \( c \cap \partial \mathcal{O} \neq \emptyset \).

(b) A *covering cell* is a cell \( c \) which shares an edge or a corner with a filled cell \( c_f \), i.e. \( c \cap c_f \neq \emptyset \).

### 5.3.2 Poincaré-type inequality for cell-paths

Given a cell \( c_0 \) and a cell-path from \( c_0 \) to either a g-cell or an lg-cell, one may express the value of a function \( u \in C_0^\infty(c_0) \) any point in \( c_0 \) as a line integral over a path within the cell path from that point to the boundary (cf. equation (5.19)). With this representation for \( u \), one may proceed in a way similar to the proof of [3, Theorem 6.30] to obtain a Poincaré-type inequality for \( c_0 \). Note that, throughout the chapter, we shall always regard functions in \( H_0^1(\mathcal{O}) \) as being defined on the whole of \( \mathbb{R}^2 \) via extension by zero.
Lemma 5.26. Let \( c_0 \) be a cell and let \( (c_1, \ldots, c_{n+1}) \) be a cell path from \( c_0 \) to a g-cell \( c_n \) or an lg-cell \( \{c_n, c_{n+1}\} \). Then, for any \( u \in H_0^1(\mathcal{C}) \),

\[
\|u\|^2_{L^2(c_0)} \leq r^2 \sum_{j=0}^{n+1} \|\nabla u\|^2_{L^2(c_j)}.
\] (5.17)

In (5.17), \( c_{n+1} \) is considered to be the empty set in the case of a cell path to a g-cell.

Proof. Assume without loss of generality that \( c_0 = [0, r]^2 \). In the case of a cell path to an lg-cell, assume without loss of generality that \( c_n \) shares an edge with \( c_{n-1} \). We first deal with the case that \( n \geq 1 \), so that \( c_0 \neq c_n \) (or \( c_0 \notin \{c_n, c_{n+1}\} \) in the case of a cell-path to an lg-cell). The easier case \( n = 0 \) will be treated separately.

For each \( j \in \{0, \ldots, n-1\} \), let \( e_j \) denote the unique edge shared by \( c_j \) and \( c_{j+1} \) (note that \( c_j \neq c_{j+1} \) by the definition of a cell path). Assume without loss of generality that \( e_0 = [0, r] \times \{0\} \). Let us parameterise each of the edges \( e_j \) by \((e_j(s))_{s \in [0, r]} \) such that the path \( s \mapsto e_j(s) \) has unit speed. It suffices to specify the point \( e_j(0) \) or the point \( e_j(r) \) in order to define the entire parameterisation \((e_j(s))_{s \in [0, r]} \).

1. Define \((e_0(s))_{s \in [0, r]} \) by \( e_0(0) = (0, 0) \), so that \( e_0(s) = (s, 0) \). If \( n = 1 \), then we are done. If \( n \geq 2 \), then the parameterisations are defined recursively as follows. Note that for each \( j \in \{1, \ldots, n-1\} \), we have \( c_{j-1} \neq c_{j+1} \) by the definition of a cell-path and so \( e_j \neq e_{j-1} \).

2. For \( j \in \{1, \ldots, n-1\} \), if \( e_{j-1} \) is parallel to \( e_j \), then we call \( e_j \) a straight tile. In this case, define \((e_j(s))_{s \in [0, r]} \) by the condition that \( e_j(0) \) is connected by an edge of \( c_j \) to \( e_{j-1}(0) \), so that \( e_j(r) \) is connected by an edge of \( c_j \) to \( e_{j-1}(r) \).

3. For \( j \in \{1, \ldots, n-1\} \), if \( e_{j-1} \) is perpendicular to \( e_j \), then we call \( e_j \) a corner tile. If \( e_j \) and \( e_{j-1} \) share the point \( e_{j-1}(0) \), then \( e_j \) is said to be positively oriented. In this case, define \((e_j(s))_{s \in [0, r]} \) by the condition that \( e_j(0) = e_{j-1}(0) \). On the other hand, if \( e_j \) and \( e_{j-1} \) share the point \( e_{j-1}(r) \), then \( e_j \) is said to be negatively oriented. In this case, define \((e_j(s))_{s \in [0, r]} \) by the condition that \( e_j(r) = e_{j-1}(r) \).

Next, we construct a family of isometries \((t_j : \mathbb{R}^2 \to \mathbb{R}^2)_{j \in \{1, \ldots, n\}} \) each of which maps \([0, r]^2 \) to the cell \( c_j \). The purpose of this is to simplify the later construction of paths within each cell. Recall that any composition of translations, rotations and reflections in the plane is an isometry. This, along with the fact that \( e_j \neq e_{j-1} \) for all \( j \in \{1, \ldots, n-1\} \), is what guarantees the existence of isometries satisfying the below conditions.

1. For \( j \in \{1, \ldots, n-1\} \), if \( e_j \) is a straight tile, then choose \( t_j \) such that \( t_j(s, 0) = e_j(s) \) and \( t_j(s, r) = e_{j-1}(s) \).
5.3 An explicit Poincaré-type inequality

2. For $j \in \{1, \ldots, n-1\}$, if $c_j$ is a positively oriented corner tile, then choose $\iota_j$ so that $\iota_j(r-s,0) = e_j(s)$ and $\iota_j(r,s) = e_{j-1}(s)$.

3. For $j \in \{1, \ldots, n-1\}$, if $c_j$ is a negatively oriented corner tile, then choose $\iota_j$ so that $\iota_j(s,0) = e_j(s)$ and $\iota_j(r,r-s) = e_{j-1}(s)$.

4. Choose $\iota_n$ so that $\iota_n(s,r) = e_{n-1}(s)$ and $\iota_n([0,r]^2) = c_n$. In the case of a cell-path to an lg-cell, this implies that $\iota_n([0,r] \times [-r,0]) = c_{n+1}$.

By the density of $C_\infty_c(\mathcal{O})$ in $H_0^1(\mathcal{O})$, it suffices to show that (5.17) holds for all $u \in C_\infty_c(\mathcal{O})$. Hence, let $u \in C_\infty_c(\mathcal{O})$.

By Definitions 5.20 and 5.22 for a g-cell and an lg-cell respectively, there exists a function $w : [0,r] \to [-r,r]$ such that $u \circ \iota_n(s,w(s)) = 0$ for all $s \in [0,r]$. Note that in the case of a cell-path to a g-cell, $w$ only takes values in $[0,r]$.

Firstly, for any $s \in [0,r]$,

$$u(e_{n-1}(s)) = u \circ \iota_n(s,r) = \int_r^r \frac{\partial}{\partial t} u \circ \iota_n(s,t) dt = : I_g(s).$$
Let \( j \in \{1, \ldots, n-1\} \). If \( c_j \) is a straight tile, then for any \( s \in [0,r) \),
\[
u(e_{j-1}(s)) - \nu(e_j(s)) = u \circ t_j(s,r) - u \circ t_j(s,0) = \int_0^r \frac{\partial}{\partial t} u \circ t_j(s,t) \, dt =: I_j(s).
\]

If \( c_j \) is an corner tile, then let
\[
I_j(s) := \int_0^s \frac{\partial}{\partial t} u \circ t_j(r-s,t) \, dt + \int_{r-s}^r \frac{\partial}{\partial t} u \circ t_j(t,s) \, dt.
\]

If \( c_j \) is a positively oriented corner tile, then for any \( s \in [0,r) \),
\[
u(e_{j-1}(s)) - \nu(e_j(s)) = u \circ t_j(r,s) - u \circ t_j(r-s,0) = \bar{I}_j(s) =: I_j(s).
\]

If \( c_j \) is a negatively oriented corner tile, then for any \( s \in [0,r) \),
\[
u(e_{j-1}(s)) - \nu(e_j(s)) = u \circ t_j(r-r-s) - u \circ t_j(s,0) = \bar{I}_j(r-s) =: I_j(s).
\]

We can now express the value of \( u \) at any point in \( c_0 = [0,r]^2 \) as sum of line integrals. For any \( x,y \in [0,r] \),
\[
u(x,y) = \nu(e_0(x)) + \int_0^r \frac{\partial}{\partial t} u(x,t) \, dt = \nu_x(x) + \sum_{j=1}^{n-1} I_j(x) + \int_0^r \frac{\partial}{\partial t} u(x,t) \, dt \tag{5.18}
\]

hence
\[
\|u\|^2_{L^2(c_0)} = \int_0^r \int_0^r |\nu(x,y)|^2 \, dx \, dy \leq r \left[ \int_0^r |\nu_x(x)|^2 \, dx + \sum_{j=1}^{n-1} \int_0^r |I_j(x)|^2 \, dx + \int_0^r \left( \int_0^r \left| \frac{\partial}{\partial t} u(x,t) \right| \, dt \right)^2 \, dx \right]. \tag{5.19}
\]

Focusing on the final term in the square brackets of (5.19) and applying Cauchy-Schwarz,
\[
\int_0^r \left( \int_0^r \left| \frac{\partial}{\partial t} u(x,t) \right| \, dt \right)^2 \, dx \leq r \int_0^r \int_0^r \left| \frac{\partial}{\partial t} u(x,t) \right|^2 \, dx \, dr \leq r \|\nabla u\|^2_{L^2(c_0)}. \tag{5.20}
\]

To estimate the remaining terms, we need to use the fact that
\[
\left| \frac{\partial}{\partial t} u \circ t_j(x,t) \right| \leq |\nabla u(t_j(x,t))| \left| \frac{\partial}{\partial t} t_j(x,t) \right| \leq |\nabla u(t_j(x,t))|,
\]
where the final inequality holds since \(t_j\) is an isometry, and similarly,

\[
|\frac{\partial}{\partial t} u \circ t_j(t,y)| \leq |\nabla u(t_j(t,y))|.
\]

Focusing on the middle terms in the square brackets of (5.19), let \(j \in \{1, \ldots, n-1\}\). If \(c_j\) is a straight tile, then

\[
\int_0^r |I_j(x)|^2 dx \leq \int_0^r \left( \int_0^x |\nabla u(t_j(x,t))| dt \right)^2 dx \leq r \int_0^r \int_0^r |\nabla u(t_j(x,t))|^2 dx dt
\]

\[
= r \|\nabla u\|_{L^2(c_j)}^2.
\]

If \(c_j\) is an corner tile, then

\[
\int_0^r |I_j(x)|^2 dx \leq \int_0^r \left( \int_0^x |\nabla u(t_j(r-x,t))| dt \right)^2 dx + \int_0^r \left( \int_{r-x}^r |\nabla u(t_j(t,x))| dt \right)^2 dx
\]

\[
\leq r \left( \int_0^r \int_0^x |\nabla u(t_j(r-x,t))|^2 dx dt + \int_0^r \int_{r-x}^r |\nabla u(t_j(t,x))|^2 dx dt \right)
\]

\[
= r \|\nabla u\|_{L^2(c_j)}^2.
\]

Hence, if \(c_j\) is a positively oriented corner tile, then

\[
\int_0^r |I_j(x)|^2 dx = \int_0^r |I_j(x)|^2 dx \leq r \|\nabla u\|_{L^2(c_j)}^2
\]

and, similarly, if \(c_j\) is a negatively oriented corner tile, then

\[
\int_0^r |I_j(x)|^2 dx = \int_0^r |I_j(r-x)|^2 dx = \int_0^r |I_j(x)|^2 dx \leq r \|\nabla u\|_{L^2(c_j)}^2.
\]

Finally, letting \(h = 0\) in the case of cell-path to a g-cell and \(h = -r\) in the case of a cell-path to an lg-cell, we have

\[
\int_0^r |I_g(x)|^2 dx \leq \int_0^r \left( \int_{w(x)}^r |\nabla u(t_n(x,t))| dt \right)^2 dx
\]

\[
\leq \int_0^r \left( \int_0^r |\nabla u(t_n(x,t))| dt \right)^2 dx + \int_0^r \left( \int_h^r |\nabla u(t_n(x,t))| dt \right)^2 dx
\]

\[
\leq r \left( \|\nabla u\|_{L^2(c_1)}^2 + \|\nabla u\|_{L^2(c_n+1)}^2 \right).
\]

where \(c_{n+1}\) is considered to the empty set in the case of a cell-path to a g-cell. The proof for the case \(n \geq 1\) is completed by substituting estimates (5.20)-(5.24) into (5.19).
The case $n = 0$ is similar. Assume that $c_0 = [0, r]^2$ and in the lg-cell case, that $c_1 = [0, r] \times [-r, 0]$. Then there exists a function $w : [0, r] \rightarrow [-r, r]$ such that

$$u(x, y) = \int_{w(x)}^y \frac{\partial}{\partial t} u(x, t) \, dt \quad ((x, y) \in c_0)$$

and the proof proceeds as before. \qed

### 5.3.3 Construction of the cell-paths

Next, we need to construct cell paths from any covering cell to a g-cell or an lg-cell. The first step is to show that there is a g-cell or an lg-cell in the 1-cell neighbourhood of a filled cell, provided the path-connected components of $\partial \mathcal{O}$ all have large enough diameter. We shall need the fact that

$$\text{diam}(A) \leq 2 \inf_{x \in A} \sup_{y \in A} |x - y|. \quad (5.25)$$

for any bounded set $A \subset \mathbb{R}^d$.

![Figure 5.5 Example sketches for some of the cases (A), (B), (C) in the proof of Lemma 5.27](image)

**Lemma 5.27.** If $Q(\partial \mathcal{O}) > 4\sqrt{2}r$, then for any filled cell $c_0$ there exists a g-cell or an lg-cell contained in $D_1[c_0]$.

**Proof.** Let $c_0$ be a filled cell. There exists a path-connected component $\Gamma \subseteq \partial \mathcal{O}$ such that $\Gamma \cap c_0 \neq \emptyset$. Let $x \in \Gamma \cap c_0$. Using (5.25) and the hypothesis on $Q(\partial \mathcal{O})$,

$$2\sqrt{2}r < \frac{1}{2}Q(\partial \mathcal{O}) \leq \frac{1}{2} \text{diam}(\Gamma) \leq \sup_{y \in \Gamma} |x - y|$$
so there exists $y \in \Gamma$ with $|x - y| > 2\sqrt{2}r$. In particular, $y \in \Gamma$ lies outside of $D_1[c_0]$. Since $\Gamma$ is path-connected, there exists a continuous path in $\Gamma$ from $y$ to $x$. Restricting this path, we deduce there exist a continuous path $\gamma : [0, 1] \to D_1[c_0]$ such that

\[
\gamma(t) \in \begin{cases} 
\partial D_1[c_0] & \text{if } t = 0 \\
\text{int} D_1[c_0] \setminus c_0 & \text{if } t \in (0, 1) \\
\partial c_0 & \text{if } t = 1
\end{cases} \quad \text{and} \quad \forall t \in [0, 1] \colon \gamma(t) \in \Gamma.
\]

Let us fix some notions that will allow us to prove the lemma. Firstly, an edge $e$ is a \textit{zeroth edge} if $\gamma(0) \in e$ and $e \subset \partial D_1[c_0]$. Since we defined an edge to be closed, there may be up to two zeroth edges.

Let $t_1 := \inf \{ t > 0 : \exists \text{ edge } e \text{ such that } \gamma(t) \in e \} \in [0, 1]$.

A \textit{first edge} is defined as any edge $e$ such that $\gamma(t_1) \in e$ and $e$ is not a zeroth edge. If $t_1 \in (0, 1)$, then the first edge is unique since $\gamma(t)$ can belong to at most one edge for $t \in (0, 1)$. If $t_1 = 1$, then there may be up to four first edges (indeed, this is the case if $\gamma(1)$ lies in a corner of $c_0$). If $t_1 = 0$, then the first edge is again unique. This is because $\gamma(0)$ must lie in $\partial D_1[c_0]$ and hence can only lie in at most one edge which isn’t entirely contained in $\partial D_1[c_0]$ (indeed, an edge containing $\gamma(0)$ which is contained in $\partial D_1[c_0]$ must be a zeroth edge).

If $t_1 < 1$, then there exists a unique first edge $e_1$ so we can make the following definitions. Let

\[
t_2 := \inf \{ t > 0 : \exists \text{ edge } e \text{ such that } \gamma(t) \in e \text{ and } e \neq e_1 \} \in (t_1, 1).
\]

Here, $t_2$ exists and satisfies $t_2 \leq 1$ since $\gamma(1)$ lies in at least one edge which is contained in $\partial c_0$, hence, which is not the first edge $e_1$. Also, $t_2$ satisfies $t_2 > t_1$ since the only edge that $\gamma(t)$ can intersect for $t \in (0, t_1]$ is the first edge $e_1$. A \textit{second edge} is defined as any edge $e$ such that $\gamma(t_2) \in e$ and $e \neq e_1$. Note that a second edge cannot be a zeroth edge since $t_1 > 0$. Finally, let

\[
\tilde{t}_1 := \sup \{ t \leq t_2 : \gamma(t) \in e_1 \}.
\]

If $t_1 = 1$, then $t_2$, the second edges and $\tilde{t}_1$ are not defined.

Let us now proceed onto the main part of the proof, in which we repeatedly use the continuity of the path $\gamma$. 
Suppose that \( t_1 \in (0, 1) \). Then, there exists a unique first edge \( e_1 \) and a unique cell \( c_1 \) containing \( \gamma([0, t_1]) \) (indeed, note that \( \gamma([0, t_1]) \) must be contained in the interior of a cell). \( c_1 \) must contain \( e_1 \) - let \( c_2 \) be the other cell containing \( e_1 \).

(A1) If there exists a zeroth edge contained in \( c_1 \) which is parallel to \( e_1 \), then \( c_1 \) is a g-cell.

(A2) Suppose there exists a second edge \( e \) which is contained in a cell \( c \in \{c_1, c_2\} \) and which is parallel to \( e_1 \). By the definition of a second edge, \( e \neq e_1 \). \( \gamma([\tilde{t}_1, t_2]) \) is contained in \( c \) and connects the distinct parallel edges \( e \) and \( e_1 \) of \( c \), therefore, \( c \) is a g-cell.

(A3) In the only other case, there exists a zeroth edge \( e_0 \) contained in the cell \( c_1 \) and a second edge \( e_2 \) contained in a cell \( c \in \{c_1, c_2\} \) such that both \( e_0 \) and \( e_2 \) are perpendicular to the edge \( e_1 \). It follows that \( e_0 \) and \( e_2 \) are distinct, parallel edges. Furthermore, the edges \( e_0 \) and \( e_2 \) are contained in distinct long edges of the long-cell \( \{c_1, c_2\} \), hence the long edges of \( \{c_1, c_2\} \) are connected by \( \gamma([0, t_2]) \). Since \( \gamma([0, t_2]) \) is contained in \( c_1 \cup c_2 \), \( \{c_1, c_2\} \) is an lg-cell.

We conclude that if \( t_1 \in (0, 1) \), then there is a g-cell or an lg-cell contained in \( D_1[c_0] \).

(B) Suppose that \( t_1 = 1 \). Then, \( \gamma([0, 1]) \) is contained entirely in one cell since \( \gamma(t) \) does not lie in any edge for every \( t \in (0, 1) \).

(B1) Suppose \( \gamma(1) \) is in the interior of an edge \( e \) belonging to \( c_0 \). Then the unique cell \( c \neq c_0 \) containing \( e \) also contains a zeroth edge parallel to \( e \), as well as \( \gamma([0, 1]) \) in its entirety. In this case, \( c \) is a g-cell.

(B2) In the only other case, \( \gamma(1) \) is not in the interior an edge so \( \gamma(1) \) is a corner of \( c_0 \). Then, there are four first edges, each of which is parallel and sharing a cell with exactly one of the four possible zeroth edges. Consequently, in this case the cell containing \( \gamma([0, 1]) \) in its entirety is a g-cell.

We conclude that if \( t_1 = 1 \), then there is a g-cell contained in \( D_1[c_0] \).

(C) Suppose that \( t_1 = 0 \). In this case, there exists a unique first edge \( e_1 \).

(C1) Suppose that \( \tilde{t}_1 = t_2 \). Let \( c_1 \) and \( c_2 \) be the cells sharing the edge \( e_1 \). In this case \( \gamma(0) \in \partial D_1[c_0] \) and \( \gamma(t_2) \in \partial c_0 \) belong to opposite extremal points of the edge \( e_1 \) hence belong to distinct long-edges of the long cell \( \{c_1, c_2\} \). Furthermore, since the only edge that \( \gamma([0, t_2]) \) can intersect is \( e_1 \), \( \gamma([0, t_2]) \subset c_1 \cup c_2 \) hence \( \{c_1, c_2\} \) forms an lg-cell.
Suppose, on the other hand, that \( \tilde{t}_1 < t_2 \). Then, since \( \gamma(t) \) does not lie in any edge for \( t \in (\tilde{t}_1, t_2) \), there exists a unique cell \( c_1 \) containing \( \gamma([\tilde{t}_1, t_2]) \). \( c_1 \) must contain the edge \( e_1 \) - let \( c_2 \) denote the other cell containing the edge \( e_1 \). \( c_1 \) must contain at least one second edge so we have the following possibilities.

(C2) If there exists a second edge \( e \) contained in \( c_1 \) which is parallel to \( e_1 \), then \( c_1 \) is a g-cell since \( \gamma([\tilde{t}_1, t_2]) \) connects \( e_1 \) and \( e \).

(C3) In the only other possibility, there exists a second edge contained in \( c_1 \) which is perpendicular to \( e_1 \). In this case, \( \gamma(0) \) and \( \gamma(t_2) \) are contained in distinct long-edges of the long-cell \( \{c_1, c_2\} \), hence \( \{c_1, c_2\} \) forms an lg-cell.

We conclude that if \( t_1 = 0 \), then there exists a g-cell or an lg-cell contained in \( D_1[g_0] \).

We have covered every possible case, proving the lemma.

\[ \square \]

Figure 5.6 Examples of cell-paths for different cases in the proof of Lemma 5.28.

Next we construct a cell-path for each covering cell, using the above lemma as well as the fact that there is a filled cell in the 1-cell neighbourhood of any covering cell.

**Lemma 5.28.** For any covering cell \( c_0 \), there exists a g-cell \( c_n \) (or an lg-cell \( \{c_n, c_{n+1}\} \)) contained in \( D_2[c_0] \) and a cell-path \( \{c_1, \ldots, c_{n-1}\} \) from \( c_0 \) to \( c_n \) (or to \( \{c_n, c_{n+1}\} \) resp.) such that \( c_j \) is a covering cell contained in \( D_2[c_0] \) for all \( j \in \{1, \ldots, n-1\} \).

**Proof.** Let \( c_0 \) be a covering cell. We aim to construct a g-cell \( c_g \) (or an lg-cell \( \{c_{g1}, c_{g2}\} \)) and a cell path \( P \) from \( c_0 \) to \( c_g \) (or to \( \{c_{g1}, c_{g2}\} \) resp.). If \( c_0 \) is a g-cell (or in an lg-cell), then we define \( P \) to be empty. We consider the two remaining possible cases.

(A) Suppose first that there exists a g-cell \( c_g \subset D_1[c_0] \) (or an lg-cell \( \{c_{g1}^{(1)}, c_{g2}^{(2)}\} \) with \( c_{gj}^{(j)} \subset D_1[c_0] \) for some \( j \in \{1, 2\} \). Let \( \tilde{c}_g := \text{int}(c_g) \) (or \( \tilde{c}_g := \text{int}(c_{g1}^{(1)} \cup c_{g2}^{(2)}) \) resp.). There exists a cell \( c_- \subset D_1[c_0] \setminus \tilde{c}_g \) which shares a normal edge with \( c_g \)
Spectral approximation for the Laplacian on rough domains

(or with \( \{c_{lg}^{(1)}, c_{lg}^{(2)}\} \) resp.). There exists a cell \( c_{0-} \subset D_1[c_0] \setminus \tilde{c}_g \) which shares an edge with both \( c_0 \) and \( c_- \).

Define \( P \) as any length-minimising subsequence of

\[
P_{\text{max}} := (c_{0-}, c_-)
\]

such that hypotheses (1) and (2) of Definition 5.23 are satisfied. Note that \( P \) always exists since \( P_{\text{max}} \) satisfies these hypotheses. \( P \) cannot contain \( c_0 \) or repeated elements since this would yield a shorter such subsequence. \( P \) does not contain \( c_g \) (or an element of \( \{c_{lg}^{(1)}, c_{lg}^{(2)}\} \) resp.) by definition. Consequently, \( P \) satisfies hypothesis (3) of Definition 5.23 and is a cell path. \( c_{0-} \) and \( c_0 \) are contained in \( D_1[c_0] \) and share an edge or corner with a g-cell (or an lg-cell respectively) so the elements of \( P \) are covering cells contained in \( D_1[c_0] \subset D_2[c_0] \).

(B) In the other case, there does not exist a g-cell, or an element of an lg-cell, contained in \( D_1[c_0] \). Since \( c_0 \) is a covering cell, there exists a filled cell \( c_f \subset D_1[c_0] \). There exists a cell \( c_{0f} \subset D_1[c_0] \) sharing an edge with both \( c_0 \) and \( c_f \). By Lemma 5.27, there exists a g-cell \( c_g \subset D_1[c_f] \) (or an lg-cell \( \{c_{lg}^{(1)}, c_{lg}^{(2)}\} \) contained in \( D_1[c_f] \)). Note that, by assumption, \( c_f \) and \( c_{0f} \) are distinct from \( c_g \) (or from both elements of \( \{c_{lg}^{(1)}, c_{lg}^{(2)}\} \) resp.). Let \( \tilde{c}_g := \text{int}(c_g) \) (or \( \tilde{c}_g := \text{int}(c_{lg}^{(1)} \cup c_{lg}^{(2)}) \) resp.). There exists a cell \( c_- \subset D_1[c_f] \setminus \tilde{c}_g \) which shares a normal edge with \( c_g \) (or with \( \{c_{lg}^{(1)}, c_{lg}^{(2)}\} \) resp.). There exists a cell \( c_{f-} \subset D_1[c_f] \setminus \tilde{c}_g \) which shares an edge with both \( c_f \) and \( c_- \).

Define \( P \) as any length-minimising subsequence of

\[
P_{\text{max}} := (c_{0f}, c_f, c_{f-}, c_-)
\]

such that hypotheses (1) and (2) of Definition 5.23 are satisfied. By a similar reasoning as in (A), \( P \) is a cell-path and its elements are covering cells contained in \( D_2[c_0] \).

Finally, we utilise the cell-paths that we have constructed, combined with the Poincaré-type inequality for the cell-paths, to prove the Poincaré-type inequality on \( \partial r \mathcal{O} \).
5.3.4 Proof of Theorem 5.6

Let \( \{c_j\} \) be the set of covering cells. Then, \( \partial^r \mathcal{O} \subseteq \bigcup_j c_j \).

For each \( c_j \) which is not a g-cell or in an lg-cell, fix an integer \( n_j \geq 1 \), an associated g-cell as \( [c_j]_{n_j} \) (or an associated lg-cell \( \{[c_j]_{n_j}, [c_j]_{n_j+1}\} \)) and (if \( n_j \geq 2 \)) an associated cell-path \( ([c_j]_1, ..., [c_j]_{n_j-1}) \) from \( c_j \) to \( [c_j]_{n_j} \) (or to \( \{[c_j]_{n_j}, [c_j]_{n_j+1}\} \)) resp.). If \( c_j \) is a g-cell itself then there are no associated cells and if \( c_j \) is in an lg-cell, let \( [c_j]_1 \) be the other cell in the lg-cell.

For each \( j \), in the case of an associated g-cell, let \( N_j := n_j \) and in the case of an associated lg-cell let \( N_j := n_j + 1 \). Additionally, in the case that \( c_j \) is a g-cell, let \( N_j = 0 \) and in the case that \( c_j \) is in an lg-cell, let \( N_j = 1 \). By Lemma 5.28, we can choose \( [c_j]_k \) such that for each \( j \) and each \( k \in \{1, ..., N_j\} \), \( [c_j]_k \) is a covering cell contained in \( D_2[c_j] \) and \( (c_j, [c_j]_1, ..., [c_j]_{N_j}) \) consists of distinct elements.

Applying Lemma 5.26, we have,

\[
\|u\|_{L^2(\partial^r \mathcal{O})}^2 \leq \sum_j \|u\|_{L^2(c_j)}^2 \leq r^2 \sum_j \left( \|\nabla u\|_{L^2(c_j)}^2 + \sum_{k=1}^{N_j} \|\nabla u\|_{L^2([c_j]_k)}^2 \right) \tag{5.26}
\]

where the sum over \( k \) is empty in the case \( N_j = 0 \). Since the associates to a given covering cell are in its 2-cell neighbourhood, each covering cell can be an associate to at most 24 other covering cells (indeed, there are 25 cells in a 2-cell neighbourhood). Furthermore, the associates to a given covering cell are distinct and each associate \( [c_j]_k \) is a covering cell so it follows from (5.26) that

\[
\|u\|_{L^2(\partial^r \mathcal{O})}^2 \leq 25r^2 \sum_j \|\nabla u\|_{L^2(c_j)}^2 \leq 25r^2 \|\nabla u\|_{L^2(\partial^2 \sqrt{2} \mathcal{O})}^2
\]

where the last inequality holds since \( \text{int}(\bigcup_j c_j) \subseteq \partial^2 \sqrt{2} \mathcal{O} \).

5.4 Mosco convergence

In this section, we establish a general Mosco convergence theorem and apply it to pixelated domain approximations. We will make use of the notion of an \( \varepsilon \)-dilation \( \text{dil}_\varepsilon(A) \) of a set \( A \subseteq \mathbb{R}^d \) - recall that this is defined by equation (5.4).
5.4.1 From uniform Poincaré-type inequalities to Mosco convergence

The first step is to prove Mosco convergence for sequences of domains \((\mathcal{O}_n)\) which satisfy a Hausdorff convergence condition to a limit domain \(\mathcal{O}\) and which verify a certain Poincaré-type inequality uniformly for the whole sequence. Such a uniform Poincaré inequality does not follow immediately from the results of the previous section, but will be established in Section 5.4.2 under suitable hypotheses.

The following fact shall be useful.

**Lemma 5.29.** For any non-empty, bounded sets \(A, B \subset \mathbb{R}^d\), we have

\[
\sup_{x \in A^c \cap B} \text{dist}(x, \partial B) \leq d_H(A, B) + d_H(\partial A, \partial B).
\]

**Proof.** This holds because

\[
\sup_{x \in A^c \cap B} \text{dist}(x, \partial B) \leq \sup_{x \in A^c \cap B} \text{dist}(x, \partial A) + d_H(\partial A, \partial B) = \sup_{x \in A^c \cap B} \text{dist}(x, A) + d_H(\partial A, \partial B) \leq d_H(A, B) + d_H(\partial A, \partial B).
\]

The proof of the next proposition uses a construction of certain cut-off functions to directly prove that the two conditions in Definition 5.1 for Mosco convergence hold. Note that the regularity of the limit domain \(\mathcal{O}\) is not yet required. We do require, however, that the Lebesgue measure of the boundary \(\partial \mathcal{O}\) vanishes, which ensures that the Lebesgue measure of the collar neighbourhood \(\partial \varepsilon \mathcal{O}\) tends to 0 as \(\varepsilon \to 0\).

**Proposition 5.30.** Let \(\mathcal{O} \subset \mathbb{R}^d\) and \(\mathcal{O}_n \subset \mathbb{R}^d\), \(n \in \mathbb{N}\), be bounded, open sets such that the following holds:

(a) \(l(n) := d_H(\mathcal{O}, \mathcal{O}_n) + d_H(\partial \mathcal{O}, \partial \mathcal{O}_n) \to 0\) as \(n \to \infty\).

(b) There exist

(i) \((f(n))_{n \in \mathbb{N}}\) such that \(2l(n) \leq f(n)\) for all \(n \in \mathbb{N}\) and \(f(n) \to 0\) as \(n \to \infty\),

(ii) constants \(C, \alpha > 0\) independent of \(n\) and \(u\)

such that, if either \(V = \mathcal{O}\) or \(V = \mathcal{O}_n\) for some large enough \(n \in \mathbb{N}\), then for all \(u \in H^1_0(V)\) we have

\[
\|u\|_{L^2(\partial f(n)V)} \leq C f(n) \|
\nabla u\|_{L^2(\partial \alpha f(n)V)}.
\]

(5.27)
5.4 Mosco convergence

(c) \( \mu_{\text{leb}}(\partial \mathcal{O}) = 0. \)

Then, \( \mathcal{O}_n \) converges to \( \mathcal{O} \) in the Mosco sense as \( n \to \infty \).

Proof. Throughout the proof, let \( L^p \) denote \( L^p(\mathbb{R}^d) \) for \( p = 2, \infty \) and let \( H^1 \) denote \( H^1(\mathbb{R}^d) \). All limits will be as \( n \to \infty \).

Define function \( \tilde{\chi} : \mathbb{R}^+ \to [0, 1] \) by

\[
\tilde{\chi}(t) := \begin{cases} 
  t & \text{if } t \in [0, 1) \\
  1 & \text{if } t \in [1, \infty)
\end{cases}
\]

(5.28)

\( \tilde{\chi} \) is weakly differentiable with \( \| \tilde{\chi}' \|_{L^\infty} = 1. \) \( \tilde{\chi} \) will be used in the construction of a cut-off function \( \chi_n \) in both Step 1 and Step 2 below. We shall also require the following two facts. Firstly, for any \( A \subset \mathbb{R}^d \) with piecewise smooth boundary, the function \( x \mapsto \text{dist}(x, A) \) is continuous and piecewise smooth hence weakly differentiable. Furthermore, since

\[
|\text{dist}(x, A) - \text{dist}(y, A)| \leq |x - y| \quad (x, y \in \mathbb{R}^d),
\]

the \( L^\infty \) norm of \( x \mapsto \nabla_x \text{dist}(x, A) \) is bounded by 1.

Step 1 (Mosco convergence condition (1)). Let \( u_n \in H^1_0(\mathcal{O}_n), n \in \mathbb{N} \), and suppose that \( u_n \rightharpoonup u \) in \( H^1 \) for some \( u \in H^1 \). We aim to show that \( u \in H^1_0(\mathcal{O}) \).

Let \( P : H^1 \to H^1_0(\mathcal{O}) \) be the orthogonal projection. If \( (w_n) \subset H^1_0(\mathcal{O}) \) and \( w_n \rightharpoonup u \) in \( H^1 \) then

\[
\langle u, (1 - P) \phi \rangle_{H^1} = \lim_{n \to \infty} \langle w_n, (1 - P) \phi \rangle_{H^1} = 0 \quad (\phi \in H^1)
\]

so \( u \in H^1_0(\mathcal{O}) \). Hence it suffices to show that there exists \( w_n \in H^1_0(\mathcal{O}) \) such that \( w_n \rightharpoonup u \) in \( H^1 \).

Assume without loss of generality that \( f(n) > 0 \) for all \( n \in \mathbb{N} \). For each \( n \in \mathbb{N} \), let \( A_n \subset \mathbb{R}^d \) be an open neighbourhood of \( \mathcal{O}^c \) with piecewise smooth boundary such that \( A_n \cap \mathcal{O} \subseteq \partial f(n)/4 \mathcal{O} \) (\( A_n \) can be constructed by an open cover of balls of radius \( f(n)/4 \) for instance).

Define a cut-off function \( \chi_n : \mathbb{R}^d \to [0, 1] \) by

\[
\chi_n(x) = \tilde{\chi}(4f(n)^{-1} \text{dist}(x, A_n)) \quad (x \in \mathbb{R}^d).
\]

(5.29)

Then, \( \chi_n = 0 \) on an open neighbourhood of \( \mathcal{O}^c \) and \( \chi_n(x) = 1 \) for any \( x \in \mathcal{O}_n \) outside the set

\[
\mathcal{U}_n := \{ x \in \mathcal{O}_n : \text{dist}(x, \mathcal{O}^c) \leq f(n)/2 \}.
\]
By the piecewise smoothness of $\partial A_n$, $\chi_n$ is weakly differentiable and, by an application of the chain rule, 
\[ \|\nabla \chi_n\|_{L^\infty} \leq 4f(n)^{-1}. \]  
(5.30)

By Lemma 5.29, we have 
\[ \sup_{x \in \mathcal{O} \cap \partial A_n} \text{dist}(x, \partial \mathcal{O}_n) \leq l(n) \leq \frac{f(n)}{2}. \]  
(5.31)

We claim that $\mathcal{Y}_n \subset \partial f(n) \partial \mathcal{O}_n$. To see this, let $x \in \mathcal{Y}_n$. Then there exists $y \in \partial \mathcal{O}_n$ with $|x - y| \leq f(n)/2$. If $y \in \partial \mathcal{O}_n$, then inequality (5.31) implies that \( \text{dist}(y, \partial \mathcal{O}_n) \leq f(n)/2 \) so \( \text{dist}(x, \partial \mathcal{O}_n) \leq f(n) \). If $y \notin \partial \mathcal{O}_n$ on the other hand, then, since $x \in \partial \mathcal{O}_n$, \( \text{dist}(x, \partial \mathcal{O}_n) \leq |x - y| \leq f(n)/2 \) proving the claim.

Furthermore, for any $x \in \mathcal{Y}_n$, we have 
\[ \text{dist}(x, \partial \mathcal{O}) \leq l(n) + \text{dist}(x, \partial \mathcal{O}_n) \leq l(n) + f(n) \]
so by hypothesis (c) and continuity of measures from above,
\[ \mu_{\text{leb}}(\mathcal{Y}_n) \leq \mu_{\text{leb}}(\text{dil}_{l(n)+f(n)}(\partial \mathcal{O})) \to \mu_{\text{leb}}(\partial \mathcal{O}) = 0. \]

Let $w_n := \chi_n u_n$. Then, since $\chi_n = 0$ on an open neighbourhood of $\partial \mathcal{O}$, we have $w_n \in H^1_0(\mathcal{O})$ and it suffices to show that $w_n = \chi_n u_n \to u$ in $H^1$. Let $\phi \in H^1$ be an arbitrary test function. Firstly, we have,
\[ \langle \chi_n u_n - u, \phi \rangle_{H^1} \leq \left[ \langle \chi_n u_n - u, \phi \rangle_{L^2} \right] + \left[ \langle \nabla (\chi_n u_n) - \nabla u, \nabla \phi \rangle_{L^2} \right]. \]  
(A1)

(A2)

Focusing on the term (A1),
\[ \left| \langle \chi_n u_n - u, \phi \rangle_{L^2} \right| \leq \left| \langle \chi_n u_n - u, \phi \rangle_{L^2} \right| + \left| \langle u_n - u, \phi \rangle_{L^2} \right| \]
\[ \leq \|u_n\|_{L^2(\mathcal{Y}_n)} \|\phi\|_{L^2(\mathcal{Y}_n)} + \|u_n - u, \phi \|_{L^2} \to 0. \]

Here, the second inequality holds since $u_n = 0$ almost everywhere outside $\partial \mathcal{O}$ and so $\chi_n u_n = u_n$ almost everywhere outside $\mathcal{Y}_n$. The limit holds by the weak convergence of $(u_n)$ as well as the fact that $\mu_{\text{leb}}(\mathcal{Y}_n) \to 0$. Focusing on the term (A2),
\[ \left| \langle \nabla (\chi_n u_n) - \nabla u, \nabla \phi \rangle_{L^2} \right| \leq \left[ \langle \nabla (\chi_n u_n) - \nabla u_n, \nabla \phi \rangle_{L^2} \right] + \left| \langle \nabla u_n - \nabla u, \nabla \phi \rangle_{L^2} \right]. \]  
(B1)

(B2)
The term (B2) tends to zero by the weak convergence of \((u_n)\). Focusing on the term (B1),

\[
\| \langle \nabla (\chi_n u_n) - \nabla u_n, \nabla \phi \rangle \|_{L^2} \leq \| \langle \nabla \chi_n u_n, \nabla \phi \rangle \|_{L^2} + \| \langle \nabla (\chi_n u_n), \nabla \phi \rangle \|_{L^2} \\
\leq \| \nabla u_n \|_{L^2(\Omega_n)} \| \nabla \phi \|_{L^2(\Omega_n)} + \| \nabla \chi_n \nabla u_n \|_{L^2(\Omega_n)} \| \nabla \phi \|_{L^2(\Omega_n)}
\]

where in the second inequality we used the fact that \(\chi_n \nabla u_n = \nabla u_n\) almost everywhere outside \(\Omega_n\) and the fact that \(\text{supp}(\nabla (\chi_n)) \cap \partial_\Omega \subseteq \bar{\Omega}_n\). The term (C1) tends to zero since \((u_n)\) is bounded in \(H^1\) and \(\mu_{\text{leb}}(\Omega_n) \to 0\). Focusing on the term (C2), notice first that, by the assumed Poincaré-type inequality (5.27),

\[
\| u_n \|_{L^2(\Omega_n)} \leq \| u_n \|_{L^2(\partial_\Omega \Omega_n)} \leq C f(n) \| \nabla u_n \|_{L^2(\partial_\Omega \Omega_n)}
\]

and so, using (5.30),

\[
\| \nabla \chi_n \|_{L^\infty} \| u_n \|_{L^2(\Omega_n)} \| \nabla \phi \|_{L^2(\Omega_n)} \leq 4C \| \nabla u_n \|_{L^2(\partial_\Omega \Omega_n)} \| \nabla \phi \|_{L^2(\Omega_n)} \to 0.
\]

It follows that the term (A2) tends to zero, that \(w_n \to u\) in \(H^1\) and hence that \(u \in H^1_0(\partial\Omega)\).

**Step 2 (Mosco convergence condition (2)).** Let \(u \in H^1_0(\partial\Omega)\) - we aim to show that there exists \(u_n \in H^1_0(\partial\Omega_n)\) such that \(u_n \to u\) in \(H^1\). Note that in this part of the proof, we shall redefine \(A_n, \chi_n\) and \(\Omega_n\).

For each \(n \in \mathbb{N}\), let \(A_n \subset \mathbb{R}^d\) be an open neighbourhood of \(\partial_\Omega^c\) with piecewise smooth boundary such that \(A_n \cap \partial_\Omega \subseteq \partial f(n)/4 \partial_\Omega_n\). Define a cut-off function \(\chi_n : \mathbb{R}^d \to [0, 1]\) by

\[
\chi_n(x) = \tilde{\chi}(4f(n)^{-1} \text{dist}(x, A_n)) \quad (x \in \mathbb{R}^d).
\]

Then, \(\chi_n = 0\) on an open neighbourhood of \(\partial_\Omega^c\) and \(\chi_n(x) = 1\) for any \(x \in \partial\Omega\) outside the set

\[
\Omega_n := \{x \in \partial\Omega : \text{dist}(x, \partial_\Omega^c) \leq f(n)/2\}.
\]

\(\chi_n\) is weakly differentiable and, by an application of the chain rule,

\[
\| \nabla \chi_n \|_{L^\infty} \leq 4f(n)^{-1}.
\]

By Lemma 5.29,

\[
\sup_{x \in \partial_\Omega^c \cap \partial\Omega} \text{dist}(x, \partial\Omega) \leq l(n) \leq \frac{f(n)}{2}
\]

so, by a similar reasoning as in Step 1, we have \(\Omega_n \subseteq \partial f(n) \partial\Omega\). By hypothesis (c) and continuity of measures from above, \(\mu_{\text{leb}}(\Omega_n) \to 0\).
Let $u_n := \chi_n u$. Then $u_n \in H^1_0(\Omega_n)$ since $\chi_n$ vanishes on an open neighbourhood of $\partial^c \Omega_n$. Firstly,
\[
\|u_n - u\|_{H^1} \leq \left( \|\chi_n u - u\|_{L^2} + \|\nabla (\chi_n u) - \nabla u\|_{L^2} \right)_{(D1)} \quad \text{and} \quad \|\nabla (\chi_n u) - \nabla u\|_{L^2} \leq \left( \|\nabla (\chi_n u)\|_{L^2} + \|\nabla (\chi_n u) - \nabla u\|_{L^2} \right)_{(D2)}.
\]

Focusing on the term (D1) and using the fact that $\chi_n u = u$ almost everywhere outside $\mathcal{U}_n$,
\[
\|\chi_n u - u\|_{L^2} = \|\chi_n u - u\|_{L^2(\mathcal{U}_n)} \leq \|u\|_{L^2(\mathcal{U}_n)} \to 0.
\]

Focusing on the term (D2), we have
\[
\|\nabla (\chi_n u) - \nabla u\|_{L^2} \leq \left( \|\nabla (\chi_n u) - \nabla u\|_{L^2} + \|\nabla (\chi_n u)\|_{L^2} \right)_{(E1)} + \left( \|\nabla (\chi_n u)\|_{L^2} \right)_{(E2)}.
\]

The term (E1) tends to zero by the same reasoning that was applied to (D1). Focusing on the term (E2), notice first that, by the assumed Poincaré-type inequality (5.27),
\[
\|u\|_{L^2(\mathcal{U}_n)} \leq \|u\|_{L^2(\partial^0 \Omega_n)} \leq C f(n) \|\nabla u\|_{L^2(\partial^0 \Omega_n)},
\]
and so, by (5.33),
\[
\|\nabla (\chi_n u)\|_{L^2} = \|\nabla (\chi_n u)\|_{L^2(\mathcal{U}_n)} \leq 4 f(n)^{-1} \|u\|_{L^2(\mathcal{U}_n)} \leq 4C \|\nabla u\|_{L^2(\partial^0 \Omega_n)} \to 0.
\]

It follows that the term (D2) tends to zero hence $u_n \to u$ strongly in $H^1$ as required.

\section*{5.4.2 Characterisation of $\partial \Omega_n$ for large $n$}

In order to verify the uniform Poincaré-type inequality needed to apply Proposition 5.30, we shall require additional hypotheses, such as regularity of the limit domain $\Omega$ and $\#_c \text{int}(\partial^c) = \#_i(\partial^c) < \infty$. With these hypotheses at hand, we shall provide in Proposition 5.38 a characterisation of some geometric properties of the boundaries of sequences of domains $\Omega_n$, for large $n$. Roughly speaking, we shall prove that for each connected component $\partial D_j$ of $\partial \Omega$, there exists a “large” path-connected subset $\gamma_n^{(j)}$ of $\partial \Omega_n$ such that $\gamma_n^{(j)}$ has comparable diameter to $\partial D_j$, and every other point in $\partial \Omega_n$ is close to one of the large subsets $\gamma_n^{(j)}$. Then, in Section 5.4.3, this characterisation is used in conjunction with the explicit Poincaré-type inequality of Theorem 5.6 to obtain the general Mosco result Theorem 5.3.

Let us collect some geometric and topological lemmas in preparation for the proof of Proposition 5.38. Firstly, we shall require the following basic fact:

An open set $A \subset \mathbb{R}^d$ is regular if and only if $A^c \subset \mathbb{R}^d$ is the closure of an open set.
Next, let us solidify a notion of an outer boundary for a domain. In particular, this notion shall be crucial in defining boundary subsets $\gamma_n^{(j)}$.

**Definition 5.31.** The outer boundary $\partial^{\text{out}}A$ of a bounded, connected set $A \subset \mathbb{R}^d$ is defined as the boundary $\partial \Gamma$ of the unique unbounded connected component $\Gamma$ of $A^c$.

The next lemma is required to ensure that the large boundary subsets $\gamma_n^{(j)}$ are path-connected.

**Lemma 5.32.** Suppose that $A \subset \mathbb{R}^2$ is bounded, connected and either open or closed. If $\partial A$ locally connected, then $\partial^{\text{out}}A$ is path-connected.

**Proof.** It is a consequence of the Carathéodory theorem [56, Theorem 2.1] that if $K \subset \mathbb{R}^2$ is a connected, compact set with $\mathbb{R}^2 \setminus K$ connected and there exists a locally connected, compact set $L$ such that $\partial K \subseteq L \subseteq K$, then there exists a continuous, surjective map $\Psi : \mathbb{R}^2 \setminus B_1(0) \to \mathbb{R}^2 \setminus \text{int}(K)$. Restricting the map $\Psi$ yields a continuous, surjective map $\gamma : \partial B_1(0) \to \partial K$ (the so-called Carathéodory loop), showing that $\partial K$ is path-connected.

Let $A \subset \mathbb{R}^2$ be bounded and connected with $\partial A$ locally connected. Let $\Gamma$ denote the unique unbounded connected component of $A^c$ and let $E := A^c \setminus \Gamma$.

Consider first the case that $A$ is closed. Let $K := A \cup E$. Then $K$ is compact, connected and $K^c = \Gamma$ is connected. Let $L := \partial A$. Then, $L$ is compact, locally connected and satisfies $\partial^{\text{out}}A = \partial K \subseteq L \subseteq K$ so $\partial^{\text{out}}A$ is path-connected.

Now suppose that $A$ is open. $\partial^{\text{out}}A = \partial \Gamma$ is connected since $\Gamma$ and $\Gamma^c = A \cup E$ are connected [45]. Furthermore, in this case, $\partial^{\text{out}}A$ is a connected component of $\partial A$ since $\partial \Gamma \subset \Gamma$ and $\Gamma$ is separated from any other connected component of $A^c$. It follows that $\partial^{\text{out}}A$ is a connected, locally connected and compact metric space hence path-connected [105, Lemma 16.4].

The next lemma gives a property of the outer boundary of a dilation of set. It shall be utilised in Proposition 5.38 to help show that every point in the boundary $\partial \tilde{\Omega}_n$ of the approximating domains is close to a large subset $\gamma_n^{(j)}$ for large $n$.

**Lemma 5.33.** If $A \subset \mathbb{R}^d$ is a bounded, connected, regular open set such that $\text{int}(A^c)$ is connected, then

$$\sup_{x \in \partial A} \text{dist}(x, \partial^{\text{out}}\text{dil}_\varepsilon(A)) \to 0 \quad \text{as} \quad \varepsilon \to 0.$$ 

**Proof.** Let $x \in \partial A$. By regularity, $A^c$ is the closure of $\text{int}(A^c)$ so there exists a sequence $(x_n) \subset \text{int}(A^c)$ with $x_n \to x$. We claim that for each $n$, there exists $\varepsilon_n > 0$ such that $x_n$ lies in the unbounded connected component of $\text{dil}_\varepsilon(A)^c$ for all $\varepsilon \in (0, \varepsilon_n]$. To see this first note that, since $\text{int}(A^c)$ is connected and $A$ is bounded, there exists an unbounded,
connected open set $V_n$ such that $\nabla_n \subset \text{int}(A^c)$ and $x_n \in V_n$. The claim follows from the fact that $V_n$ is a subset of $\text{dil}_\varepsilon(A)^c$ for small enough $\varepsilon$.

Without loss of generality, assume that $\varepsilon_{n+1} < \varepsilon_n$ for all $n$. For each $\varepsilon \in (\varepsilon_{n-1}, \varepsilon_n]$, $x$ lies in $\text{dil}_\varepsilon(A)$ and $x_n$ lies in the unbounded connected component of $\text{int}(\text{dil}_\varepsilon(A)^c)$, so,

$$\delta_\varepsilon(x) := \text{dist}(x, \partial_{\text{out}} \text{dil}_\varepsilon(A)) \leq |x - x_n|.$$ 

Since $\varepsilon_n \to 0$ monotonically as $n \to \infty$ and $|x - x_n| \to 0$ as $n \to \infty$, we have $\delta_\varepsilon(x) \to 0$ as $\varepsilon \to 0$. $\delta_\varepsilon(x)$ is equal to the distance from $x$ to the unbounded component of $\text{dil}_\varepsilon(A)^c$. Since the latter set is nested for decreasing $\varepsilon > 0$, $\delta_\varepsilon(x)$ in fact tends to zero monotonically as $\varepsilon \to 0$. Finally, $\partial A$ is compact and $\delta_\varepsilon(x)$ is continuous in $x$ so an application of Dini's theorem yields

$$\delta(x) := \sup_{x \in \partial A} \delta_\varepsilon(x) \to 0 \quad \text{as} \quad \varepsilon \to 0.$$ 

Next, we prove a couple of useful elementary topological facts.

**Lemma 5.34.** If $A, B \subset \mathbb{R}^d$ are such that $B$ is open and connected, $A \cap B \neq \emptyset$ and $\partial A \subset B^c$, then $B \subset A$.

**Proof.** Suppose for contradiction that $A^c \cap B \neq \emptyset$. $B$ is path-connected so there exists a path in $B$ from any point in $A \cap B$ to any point in $A^c \cap B$. Such a path must intersect $\partial A$ which is the desired contradiction.

**Lemma 5.35.** If $A \subset \mathbb{R}^d$ is a connected open set such that $\#_c(A^c) < \infty$, then the union of $A$ with any connected component of $A^c$ is open and connected.

**Proof.** Let $D$ be any connected component of $A^c$. Since $\#_c(A^c) < \infty$, there exists an open neighbourhood $U$ of $D$ such that $U$ does not intersect any other connected component of $A^c$. Consequently, $U \setminus D \subset A$ and so $A \cup D = A \cup U$. The lemma follows from the fact that the union of two open, connected sets with nonempty intersection is open and connected.

In Proposition 5.38, we shall assume that the limit domain $O$ is bounded, regular and satisfies $\#_c(\text{int}(O^c)) = \#_c(\partial O^c) < \infty$. The next lemma collects some properties of domains satisfying these hypotheses. Intuitively, such a domain has a finite number of holes $D_1, \ldots, D_N$ which do not touch each other and which do not touch the unbounded exterior of the domain. The set $D_{N+1}$ below is essentially the domain $O$ with all the holes filled in.
Lemma 5.36. Suppose that $\mathcal{O} \subset \mathbb{R}^d$ is a bounded, connected, regular open set such that $\#_c \text{int}(\mathcal{O}^c) = \#_c (\mathcal{O}^c) < \infty$. Let $D_1, \ldots, D_N \subset \mathbb{R}^d$ denote the bounded connected components of $\text{int}(\mathcal{O}^c)$. Let $D_{N+1} \subset \mathbb{R}^d$ denote the complement of the unbounded connected component of $\mathcal{O}^c$. Then,

(a) the collection of closed sets $\overline{D}_1, \ldots, \overline{D}_N, \overline{D}_{N+1}^c$ is pairwise disjoint,

(b) $\text{int}(D_j^c)$ is connected for each $j \in \{1, \ldots, N+1\}$,

(c) $D_j$ is regular for each $j \in \{1, \ldots, N+1\}$ and

(d) $\partial D_1, \ldots, \partial D_{N+1}$ are the connected components of $\partial \mathcal{O}$.

Proof. Let $E_{N+1} \subset \mathbb{R}^d$ denote the unbounded connected component of $\text{int}(\mathcal{O}^c)$, so that

$$\text{int}(\mathcal{O}^c) = D_1 \cup \cdots \cup D_N \cup E_{N+1}. \quad (5.34)$$

By the regularity of $\mathcal{O}$ and the fact the closure of the union of two sets is the union of the closure,

$$\mathcal{O}^c = \overline{\text{int}(\mathcal{O}^c)} = \overline{D}_1 \cup \cdots \cup \overline{D}_N \cup \overline{E}_{N+1}. \quad (5.35)$$

By construction, we have that $\#_c \text{int}(\mathcal{O}^c) = N+1$. By the hypothesis $\#_c \text{int}(\mathcal{O}^c) = \#_c (\mathcal{O}^c)$, we must in fact have $\#_c (\mathcal{O}^c) = N+1$ and this can only hold if the collection of closed sets $\overline{D}_1, \ldots, \overline{D}_N, \overline{E}_{N+1}$ is exactly the collection of connected components of $\mathcal{O}^c$ and hence must be pairwise disjoint. In particular, since $\overline{E}_{N+1}$ is the unique unbounded connected component of $\mathcal{O}^c$, we must have $D_{N+1} = (\overline{E}_{N+1})^c$, proving (a).

Moving on to the proof of (b), first note that we have the disjoint union

$$\mathbb{R}^d = \mathcal{O} \cup \overline{D}_1 \cup \cdots \cup \overline{D}_N \cup D_{N+1}^c$$

and so, for any $j \in \{1, \ldots, N\}$,

$$\text{int}(D_j^c) = (D_j)^c = \mathcal{O} \cup \left( \bigcup_{k=1 \atop k \neq j}^N \overline{D}_k \right) \cup D_{N+1}^c. \quad (5.36)$$

By $N$ successive applications of Lemma 5.35, we see that the right hand side of (5.36) is connected, proving (b) for $j \in \{1, \ldots, N\}$. The proof of (b) for $j = N+1$ is immediate since $\text{int}(D_{N+1}^c) = E_{N+1}$.

Next, focus on the regularity of $D_j$. Since the interior of the union of two disjoint closed sets is the union of the interior of those sets, we have

$$\text{int}(\mathcal{O}^c) = \text{int}(\overline{D}_1) \cup \cdots \cup \text{int}(\overline{D}_N) \cup \text{int}(E_{N+1}). \quad (5.37)$$
Combined with (5.34) and disjointedness, (5.37) implies that, for any \( j \in \{1,...,N\} \),

\[
\text{int}(D_j) = D_j \cap (\text{int}(D_1) \cup \cdots \cup \text{int}(D_N) \cup \text{int}(E_{N+1}))
= D_j \cap (D_1 \cup \cdots \cup D_N \cup E_{N+1}) = D_j,
\]

that is, \( D_j \) is regular. \( D_{N+1} \) is also regular because \( D_{N+1}^c = E_{N+1} \) and \( E_{N+1} \) is open.

The fact that \( D_j \) is an open, connected subset of \( \mathbb{R}^d \) and \( D_j^c \) is connected ensures that \( \partial D_j \) is connected for each \( j \in \{1,...,N+1\} \) [45]. Then (d) follows from (5.35) and the fact that the collection of closed connected sets \( \partial D_1, ..., \partial D_{N+1} \) is pairwise disjoint.

The following lemma, concerning Hausdorff convergence for the boundaries of approximations of an open set from below, follows immediately from Lemma 5.41 below.

**Lemma 5.37.** If \( A \subset \mathbb{R}^d \) and \( A_n \subset \mathbb{R}^d \), \( n \in \mathbb{N} \), are bounded open sets such that \( A_n \subset A \) for all \( n \in \mathbb{N} \) and \( A = \bigcup_{n=1}^{\infty} A_n \), then \( d_H(\partial A_n, \partial A) \to 0 \) as \( n \to \infty \).

---

**Proposition 5.38.** Suppose that \( \partial \subset \mathbb{R}^2 \) is a bounded, connected, regular open set such that \( \mu_{\text{leb}}(\partial \partial) = 0 \) and \( \#_c(\text{int}(\partial^c)) = \#_c(\partial^c) < \infty \). Suppose that \( \partial_n \subset \mathbb{R}^2 \), \( n \in \mathbb{N} \), is a collection of bounded open sets such that \( \partial \partial_n \) is locally connected for all \( n \in \mathbb{N} \) and

\[
l(n) = d_H(\partial \partial_n, \partial \partial) + d_H(\partial \partial_n, \partial \partial) \to 0 \quad \text{as} \quad n \to \infty.
\]

Let \( D_j \subset \mathbb{R}^2 \), \( j \in \{1,...,N+1\} \), denote the sets in Lemma 5.36. Then, there exists:

1. \( n_0 \in \mathbb{N} \),
2. a sequence \( \varepsilon(n) > 0 \), \( n \geq n_0 \), with \( \varepsilon(n) \to 0 \) as \( n \to \infty \) and \( \varepsilon(n) \geq 2l(n) \)
Proof. Step 1 (Construction of $\gamma_n^{(j)}$). Let
\[ F_n^{(j)} := \text{int}(D_j \setminus \partial l(n)D_j) \quad (j \in \{1, \ldots, N+1\}, n \in \mathbb{N}). \]
Choose any point $x_0 \in D_j$. Then there exists $n_0 \in \mathbb{N}$ large enough such that $x_0 \in F_n^{(j)}$ for all $n \geq n_0$. For every $j \in \{1, \ldots, N+1\}$ and $n \geq n_0$, define $F_n^{(j)}$ as the unique path-connected component of the open set $F_n^{(j)}$ containing the point $x_0$.

$F_n^{(j)}$ is open, bounded, connected and satisfies
\[ F_n^{(j)} \subset F_{n+1}^{(j)} \subset D_j \]
for all $n$. Furthermore, since any path in $D_j$ from $x_0$ to any point $x \in D_j$ lies in $F_n^{(j)}$ for all large enough $n$, we have $x \in F_n^{(j)}$ for all large enough $n$ and so
\[ \bigcup_{n=1}^{\infty} F_n^{(j)} = D_j. \]
By Lemma 5.37, we have
\[ \varepsilon_1^{(j)}(n) := d_H(\partial F_n^{(j)}, \partial D_j) \to 0 \quad \text{as} \quad n \to \infty \quad (j \in \{1, \ldots, N+1\}, n \geq n_0). \quad (5.40) \]

Let us now focus on the case $j \in \{1, \ldots, N\}$. The definitions of $F_n^{(j)}$ and $l(n)$ ensure that $\partial \mathcal{O}_n$ does not intersect $F_n^{(j)}$ and $F_n^{(j)} \cap \mathcal{O}^c_n \neq \emptyset$ hence $F_n^{(j)} \subset \mathcal{O}^c_n$ by Lemma 5.34. Define $(\mathcal{O}^c_n)^j$ as the unique connected component of $\mathcal{O}^c_n$ such that the connected set $F_n^{(j)}$ is contained in $(\mathcal{O}^c_n)^j$.

By Lemma 5.36 (a), we can ensure that $n_0$ is large enough so that the collection of open sets
\[ \text{dil}_{2l(n)}(D_1), \ldots, \text{dil}_{2l(n)}(D_N), \text{dil}_{2l(n)}(D_{N+1}) \]
is pairwise disjoint for $n \geq n_0$. Then, for $n \geq n_0$, every point in $\partial \text{dil}_{2l(n)}(D_j)$ lies in $\mathcal{O}$ at a distance $\geq 2l(n)$ from $\partial \mathcal{O}$ so
\[ \partial \text{dil}_{2l(n)}(D_j) \subset \mathcal{O}_n \subset (\mathcal{O}^c_n)^j. \]
Since also \((\mathcal{O}_n^c)_{j} \cap \text{dil}_{2l(n)}(D_j) \neq \emptyset\), an application of Lemma 5.34 yields
\[
(\mathcal{O}_n^c)_{j} \subset \text{dil}_{2l(n)}(D_j). \tag{5.41}
\]
for all \(n \geq n_0\).

Consequently, \((\mathcal{O}_n^c)_{j}\) is bounded for \(n \geq n_0\) and we can use the notion of outer boundary (cf. Definition 5.31) to make the definition
\[
\gamma_n^{(j)} := \partial^\text{out}(\mathcal{O}_n^c)_{j} \quad (j \in \{1, \ldots, N\}, n \geq n_0). \tag{5.42}
\]
By Lemma 5.32, \(\gamma_n^{(j)}\) is path-connected. Since \(F_n^{(j)} \subset (\mathcal{O}_n^c)_{j}\) for all \(n \geq n_0\), we have
\[
\text{diam}(\gamma_n^{(j)}) \geq \text{diam}(\partial F_n^{(j)}) \geq \text{diam}(\partial D_j) - 2\varepsilon_1^{(j)}(n) \tag{5.43}
\]
where the final inequality holds by (5.40).

The construction of \(\gamma_n^{(N+1)}\) is very similar. In this case, for every \(n \geq n_0\), \(F_n^{(N+1)}\) is contained inside \(\mathcal{O}_n\) and we define \(\mathcal{O}_{n,0} \subset \mathbb{R}^d\) as the unique connected component of \(\mathcal{O}_n\) containing \(F_n^{(N+1)}\). \(\mathcal{O}_{n,0}\) is bounded because \(\mathcal{O}_n\) is bounded hence we can make the definition
\[
\gamma_n^{(N+1)} := \partial^\text{out}\mathcal{O}_{n,0} \quad (n \geq n_0). \tag{5.44}
\]
By Lemma 5.32, \(\gamma_n^{(N+1)}\) is path-connected. We have \(F_n^{(N+1)} \subset \mathcal{O}_{n,0}\) so (5.43) holds for \(j = N + 1\) and \(n \geq n_0\).

**Step 2 (Properties of \(\gamma_n^{(j)}\)).**

Let
\[
\varepsilon_2^{(j)}(n) := \sup_{x \in \partial D_j} \text{dist}(x, \partial^\text{out} \text{dil}_{2l(n)}(D_j)) \quad (j \in \{1, \ldots, N + 1\}, n \in \mathbb{N}). \tag{5.45}
\]
For each \(j \in \{1, \ldots, N + 1\}\), \(D_j\) satisfies the hypotheses of Lemma 5.33 by Lemma 5.36, hence \(\varepsilon_2^{(j)}(n) \to 0\) as \(n \to \infty\).

We claim that
\[
\sup_{x \in \partial D_j} \text{dist}(x, \gamma_n^{(j)}) \leq \max\{\varepsilon_1^{(j)}(n), \varepsilon_2^{(j)}(n)\} \tag{5.46}
\]
for each \(j \in \{1, \ldots, N + 1\}\) and large enough \(n\). Fix \(x \in \partial D_j\). By the definition of \(\varepsilon_1^{(j)}(n)\), there exists \(y_1 \in \partial F_n^{(j)}\) such that \(|y_1 - x| \leq \varepsilon_1^{(j)}(n)\). By the definition of \(\varepsilon_2^{(j)}(n)\), there exists \(y_2 \in \partial^\text{out} \text{dil}_{2l(n)}(D_j)\) such that \(|y_2 - x| \leq \varepsilon_2^{(j)}(n)\).

Focus first on the case \(j \in \{1, \ldots, N\}\). By (5.41) and the fact that \(y_2\) lies in the unbounded connected component of \(\text{dil}_{2l(n)}(D_j)^c\), \(y_2\) lies in the unbounded connected
component of the complement of \((O_n^c)\) for all \(n \geq n_0\). In addition, we have that \(y_1 \in (O_n^c)\). Consequently, the path \(\gamma\) consisting the union of a straight line from \(y_1\) to \(x\) and a straight line from \(x\) to \(y_2\) must intersect \(\gamma_n^{(j)} = \partial^{\text{out}}(O_n^c)\). Inequality (5.46) for \(j \in \{1, \ldots, N\}\) follows from the fact that every point \(y\) in the path \(\gamma\) satisfies 
\(|y - x| \leq \max\{\varepsilon_1^{(j)}(n), \varepsilon_2^{(j)}(n)\}\).

The proof of (5.46) for \(j = N + 1\) is very similar. \(y_1\) lies in \(O_{n,0}\) and \(y_2\) lies in the unbounded connected component of \((O_{n,0})^c\) so the path consisting of the union of a straight from \(y_1\) to \(x\) and a straight line from \(x\) to \(y_2\) intersects \(\gamma_n^{(N+1)} = \partial^{\text{out}}O_{n,0}\).

Let 
\[\varepsilon(n) := 2\max\{\varepsilon_1^{(1)}(n), \ldots, \varepsilon_1^{(N+1)}(n), \varepsilon_2^{(1)}(n), \ldots, \varepsilon_2^{(N+1)}(n), \bar{\varepsilon}(n)\} \quad (n \geq n_0).\]

Then (5.38) is satisfied since (5.43) holds for all \(j \in \{1, \ldots, N + 1\}\) so it remains to prove (5.39). But (5.39) follows from (5.46) by the observation that, for large enough \(n\),

\[
\sup_{x \in \partial O_n} \text{dist}(x, \gamma_n^{(1)} \cup \cdots \cup \gamma_n^{(N+1)}) \leq \bar{\varepsilon}(n) + \sup_{x \in \partial \gamma} \text{dist}(x, \gamma_n^{(1)} \cup \cdots \cup \gamma_n^{(N+1)})
\]

and, using Lemma 5.36 (d),

\[
\sup_{x \in \partial \gamma} \text{dist}(x, \gamma_n^{(1)} \cup \cdots \cup \gamma_n^{(N+1)}) \leq \max\{\sup_{x \in \partial D_{N+1}} \text{dist}(x, \gamma_n^{(1)}), \ldots, \sup_{x \in \partial D_{N+1}} \text{dist}(x, \gamma_n^{(N+1)})\}
\]

\[
\leq \max\{\varepsilon_1^{(1)}(n), \ldots, \varepsilon_1^{(N+1)}(n), \varepsilon_2^{(1)}(n), \ldots, \varepsilon_2^{(N+1)}(n)\}
\]

\[
\leq \varepsilon(n).
\]

\[\square\]

### 5.4.3 Proof of Theorem 5.3

Firstly, \(\varrho\) and \(\varrho_n, n \in \mathbb{N}\), satisfy the hypotheses of Proposition 5.38. Let \(\varepsilon(n), D_j, N\) and \(\gamma_n^{(j)}\) be as in that proposition. \(\varepsilon(n)\) satisfies \(\varepsilon(n) \geq 2\bar{\varepsilon}(n)\) and \(\varepsilon(n) \to 0\) as \(n \to \infty\) so by Proposition 5.30 it suffices to show that there exist numerical constants \(C, \alpha > 0\) such that for large enough \(n\),

\[
\forall u \in H_0^1(\varrho) : \quad \|u\|_{L^2(\partial^{\text{out}} \varrho)} \leq C \varepsilon(n) \|\nabla u\|_{L^2(\partial^{\text{out}} \varrho)}\]

and

\[
\forall u \in H_0^1(\varrho_n) : \quad \|u\|_{L^2(\partial^{\text{out}} \varrho_n)} \leq C \varepsilon(n) \|\nabla u\|_{L^2(\partial^{\text{out}} \varrho_n)}.
\]
Spectral approximation for the Laplacian on rough domains

(5.48) follows immediately from Theorem 5.6 (with $C = 5$ and $\alpha = 2\sqrt{2}$) so it remains to show (5.49).

Let

$$\mathcal{Y}_n := \left(\bigcup_{j=1}^{N+1} \mathcal{Y}_n^{(j)}\right)^c \quad (n \in \mathbb{N}). \quad (5.50)$$

By inequality (5.39) in Proposition 5.38, every point in $\partial \mathcal{O}_n$ is at most a distance $\varepsilon(n)$ from $\partial \mathcal{Y}_n = \bigcup_{j=1}^{N+1} \mathcal{Y}_n^{(j)}$ so

$$\partial \varepsilon(n) \subseteq \operatorname{dil}_{2\varepsilon(n)}(\partial \mathcal{Y}_n) = \partial 2\varepsilon(n) \mathcal{Y}_n. \quad (5.51)$$

Inequality (5.38) yields

$$Q(\partial \mathcal{Y}_n) \geq \min \{ \operatorname{diam}(\partial D_j) - \varepsilon(n) : j \in \{1, \ldots, N+1\}\}. \quad (5.52)$$

Since $D_j$ are bounded open sets, we have $\operatorname{diam}(\partial D_j) > 0$ and so $4\sqrt{2}\varepsilon(n) < Q(\partial \mathcal{Y}_n)$ for large enough $n$. Consequently, an application of Theorem 5.6 shows that

$$\|u\|_{L^2(\partial \varepsilon(n) \mathcal{O}_n)} \leq \|u\|_{L^2(\partial 2\varepsilon(n) \mathcal{Y}_n)} \leq 10\varepsilon(n) \|\nabla u\|_{L^2(\partial 4\sqrt{2}\varepsilon(n) \mathcal{Y}_n)} \quad (5.53)$$

for all large enough $n$ and all $u \in H^1_0(\mathcal{O}_n)$. Noting that any $u \in H^1_0(\mathcal{O}_n)$ must vanish almost everywhere on $\mathcal{O}_n^c$, we see that we have established (5.49) (with $C = 10$ and $\alpha = 4\sqrt{2}$), completing the proof.

**Remark 5.39.** Recall that the explicit Poincaré-type inequality of Theorem 5.6 does not require regularity of the domain. Interestingly, this is exploited in the proof of Theorem 5.3. There, Theorem 5.6 is applied to $u \in H^1_0(\mathcal{O}_n)$ as a function in $H^1_0(\mathcal{Y}_n)$, and $\mathcal{Y}_n$ is certainly not regular in general.

**Remark 5.40.** We can replace the hypothesis $Q(\partial \mathcal{O}) > 0$ with the hypothesis that the connected components of $\partial \mathcal{O}$ are path-connected. Indeed, with this replacement, the path-connected components of $\partial \mathcal{O}$ are $\partial D_1, \ldots, \partial D_{N+1}$, where $D_1, \ldots, D_{N+1}$ are the bounded, open sets of Lemma 5.36, hence

$$Q(\partial \mathcal{O}) = \min \{\operatorname{diam}(\partial D_j) : j \in \{1, \ldots, N+1\}\} > 0. \quad (5.54)$$

### 5.4.4 Hausdorff convergence for pixelated domains

We finish the section by showing that pixelation approximations (cf. Definition 5.16) satisfy the Hausdorff convergence condition of Theorem 5.3 (under suitable hypotheses). From this, we will be able to conclude that the pixelation approximations
converge in the Mosco sense, which will be utilised in the study of computational spectral problems in Section 5.5.

**Lemma 5.41.** If \( A \subset \mathbb{R}^d \) and \( A_n \subset \mathbb{R}^d \), \( n \in \mathbb{N} \), are bounded open sets such that \( A_n \subset A \) for all \( n \in \mathbb{N} \) and any compact set \( F \subset A \) is a subset of \( A_n \) for all large enough \( n \), then

\[
d_H(A, A_n) + d_H(\partial A, \partial A_n) \to 0 \quad \text{as} \quad n \to \infty.
\]

**Proof.** We have that \( d_H(\partial A_n, \partial A) = \max\{D_1, D_2\} \), where

\[
D_1 := \sup_{x \in \partial A} \text{dist}(x, \partial A_n) \quad \text{and} \quad D_2 := \sup_{x \in \partial A_n} \text{dist}(x, \partial A).
\]

Focusing on \( D_1 \), let \( \varepsilon > 0 \) and \( x \in \partial A \). By hypothesis, we can let \( N(\varepsilon, x) \subset \mathbb{N} \) be large enough so that \( B_{\varepsilon}(x) \cap A_n \neq \emptyset \) for all \( n \geq N(\varepsilon, x) \). The ball \( B_{\varepsilon}(x) \) also intersects \( A_n \subset A_n^c \) for all \( n \) so in fact \( B_{\varepsilon}(x) \) intersects \( \partial A_n \) for all \( n \geq N(\varepsilon, x) \). This shows that \( \text{dist}(x, \partial A_n) < \varepsilon \) for all \( n \geq N(\varepsilon, x) \). By compactness of \( \partial A \), we can let \( N(\varepsilon) := \sup_{x \in \partial A} N(\varepsilon, x) < \infty \). Then,

\[
\forall n \geq N(\varepsilon) : \sup_{x \in \partial A} \text{dist}(x, \partial A_n) < \varepsilon
\]

hence \( D_1 \to 0 \) as \( n \to \infty \).

Focusing on \( D_2 \), suppose for contradiction that there exists a subsequence \( (\partial A_{n_k})_{k \in \mathbb{N}} \) such that

\[
\sup_{x \in \partial A_{n_k}} \text{dist}(x, \partial A) \geq C
\]

for some \( C > 0 \) independent of \( k \). Then there exists \( x_{n_k} \in \partial A_{n_k} \), \( k \in \mathbb{N} \), such that \( \text{dist}(x_{n_k}, \partial A) \geq C \). \( B_{C/2}(x_{n_k}) \) is contained in \( A \) and intersects \( A_{n_k}^c \) for all \( k \) so there exists \( y_{n_k} \in B_{C/2}(x_{n_k}) \), \( k \in \mathbb{N} \), such that \( y_{n_k} \in A_{n_k}^c \cap A \) for all \( k \). \( (y_{n_k}) \) satisfies \( \text{dist}(y_{n_k}, \partial A) \geq C/2 > 0 \) for all \( k \). Let \( y \in \overline{A} \) be an accumulation point of \( (y_{n_k}) \). \( y \) must satisfy \( \text{dist}(y, \partial A) \geq C/2 \) so there exists \( \delta > 0 \) such that \( B_\delta(y) \subset \text{int}(A) = A \). By hypothesis, \( B_\delta(y) \subset A_n \) for all large enough \( n \). But this is a contradiction to fact that \( y \) is an accumulation point of \( y_{n_k} \in A_{n_k}^c \), \( k \in \mathbb{N} \). It follows that \( D_2 \to 0 \) as \( n \to \infty \) hence \( d_H(\partial A_n, \partial A) \to 0 \) as \( n \to \infty \).

Since \( A_n \subset A \), it remains to show that \( \sup_{x \in A} \text{dist}(x, A_n) \to 0 \). Let \( \varepsilon > 0 \). By hypothesis, there exists \( N \in \mathbb{N} \) such that \( A \setminus \partial^\varepsilon A \subset A_n \), hence \( \sup_{x \in A} \text{dist}(x, A_n) \leq \varepsilon \), for all \( n \geq N \), completing the proof.

In the next proposition, the hypothesis that the limit domain \( \mathcal{O} \) is regular is crucial. Indeed, Proposition 5.48 features an example of a non-regular domain for which the
Pixelation approximations do not converge in the Hausdorff sense. The basic idea of the proof is to introduce approximations from below \( \tilde{A}_n \) and \( E_n \) for the sets \( \partial \) and \( \text{int}(\partial^c) \) respectively which “sandwich” the boundary \( \partial \partial_n \) of the pixelated domain.

**Proposition 5.42.** If \( \partial \subseteq \mathbb{R}^d \) is a bounded, regular open set such that \( \mu_{\text{leb}}(\partial \partial) = 0 \), and \( \partial_n, n \in \mathbb{N} \), are the pixelated domains for \( \partial \), then

\[
l(n) = d_H(\partial, \partial_n) + d_H(\partial \partial, \partial \partial_n) \to 0 \quad \text{as} \quad n \to \infty.
\]

**Proof.** All limits in the proof are as \( n \to \infty \).

Define the following collection of open sets

\[
\mathcal{B} := \bigcup_{n \in \mathbb{N}} \mathcal{B}_n \quad \text{where} \quad \mathcal{B}_n := \left\{ j + \left(-\frac{1}{n}, \frac{1}{n}\right)^d : j \in \mathbb{Z}^d \right\}. \tag{5.55}
\]

The elements of \( \mathcal{B}_n \) are open boxes of side-length \( 2/n \) and hence overlap. Let \( A_n \) denote the union of all elements of \( \mathcal{B}_n \) which are subsets \( \partial \) and let \( E_n \) denote the union of all elements of \( \mathcal{B}_n \) which are subsets of \( \text{int}(\partial^c) \).

We claim that for any compact set \( F \subset \partial \), we have \( F \subset A_n \) for all large enough \( n \). Let \( \varepsilon > 0 \) be small enough so that \( \text{dil}_e(F) \subset \partial \) and let \( n \) be any positive integer which is large enough such that \( 2\sqrt{d}/n < \varepsilon \). Let \( x \in F \). There exists \( j \in \mathbb{Z}^d \) such that \( |x - j| \leq \sqrt{d}/2 \). Then,

\[
j + \left(-\frac{1}{n}, \frac{1}{n}\right)^d \subset \text{dil}_{2\sqrt{d}/n}(F) \subset \text{dil}_e(F) \subset \partial \tag{5.56}
\]

so the box \( j + \left(-\frac{1}{n}, \frac{1}{n}\right)^d \) is a subset of \( A_n \) and consequently \( x \in A_n \). It follows that \( F \subset A_n \), proving the claim.

We also have \( A_n \subset \partial \) so \( A_n \) and \( \partial \) satisfy the hypotheses of Lemma 5.41. We similarly have \( E_n \subset \text{int}(\partial^c) \) and, for any compact set \( F \subset \text{int}(\partial^c) \), \( F \subset E_n \) for all large enough \( n \). Applying Lemma 5.41 to \( A_n \) and \( B_X(0) \cap E_n \) for large enough \( X > 0 \), we obtain

\[
d_H(\partial, A_n) + d_H(\partial \partial, \partial A_n) \to 0 \tag{5.57}
\]

and

\[
d_H(B_X(0) \cap \text{int}(\partial^c), B_X(0) \cap E_n) + d_H(\partial \partial, \partial E_n) \to 0, \tag{5.58}
\]

where regularity was used in the second limit to ensure that \( \partial \text{int}(\partial^c) = \partial \partial \).

Define also the following subset of \( A_n \),

\[
\tilde{A}_n := \text{int}\left( \bigcup_{j \in A_n, j \in \mathbb{Z}^d} \left( j + \left[-\frac{1}{2n}, \frac{1}{2n}\right]^d \right) \right) \quad (n \in \mathbb{N}). \tag{5.59}
\]
5.4 Mosco convergence

Any point in $A_n$ is in a box $j + (-\frac{1}{n}, \frac{1}{n})^d$ for some $j \in A_n \cap \mathbb{Z}_n^d$ hence at most a distance $\sqrt{d}/n$ from a point in $\tilde{A}_n$. Consequently

$$d_H(A_n, \tilde{A}_n) \leq \frac{\sqrt{d}}{n}. \quad (5.60)$$

Firstly, we claim that

$$\tilde{A}_n \subseteq \mathcal{O}_n \subseteq E_n^c. \quad (5.61)$$

To see the first inclusion in (5.61), note that any grid point $j \in A_n \cap \mathbb{Z}_n^d$ is in $\mathcal{O}$ so the corresponding cell $j + [-1/(2n), 1/(2n)]^d$ is a subset of $\overline{\mathcal{O}}_n$. Focus now on the second inclusion. Any point in $x$ in $E_n$ lies in $j + (\frac{1}{n}, \frac{1}{n})^d$ for some $j \in \mathbb{Z}_n^d \cap E_n$. Since the corners of the closed box $j + [-\frac{1}{n}, \frac{1}{n}]^d$ lie in $\mathbb{Z}_n^d \cap \overline{E}_n$, $x$ lies in $j' + [-\frac{1}{2n}, \frac{1}{2n}]^d$ for some $j' \in \mathbb{Z}_n^d \cap E_n$. This shows that

$$E_n \subseteq \bigcup_{j \in E_n \cap \mathbb{Z}_n^d} \left(j + [-\frac{1}{2n}, \frac{1}{2n}]^d\right).$$

The fact that any point in $\mathbb{Z}_n^d \cap E_n$ lies in $\mathcal{O}^c$ implies that $E_n \subseteq \mathcal{O}_n^c$, proving the claim.

Secondly, we claim that

$$\mu_{\text{leb}}(E_n^c \setminus A_n) \to 0. \quad (5.62)$$

Let $X > 0$ be large enough so that $E_n^c \setminus A_n \subset B_X(0)$. Then,

$$\mu_{\text{leb}}(E_n^c \setminus A_n) = \mu_{\text{leb}}(B_X(0)) - \mu_{\text{leb}}(B_X(0) \cap A_n) - \mu_{\text{leb}}(B_X(0) \cap E_n). \quad (5.63)$$

Using continuity of measures from below, the hypothesis that $\mu_{\text{leb}}(\partial \mathcal{O}) = 0$ and regularity, we have

$$\mu_{\text{leb}}(B_X(0) \cap A_n) \to \mu_{\text{leb}}(B_X(0) \cap \mathcal{O})$$

Figure 5.8 Sketch of the domains $A_n$ (left), $\mathcal{O}_n$ (centre) and $E_n$ (right).
and
\[ \mu_{\text{leb}}(B_X(0) \cap E_n) \to \mu_{\text{leb}}(B_X(0) \cap \text{int}(\partial^c)) = \mu_{\text{leb}}(B_X(0) \cap \partial^c). \]

It follows that the right hand side of (5.63) tends to zero, proving the claim.

Next we claim that
\[ \sup_{x \in \partial \Omega_n} \text{dist}(x, \partial A_n \cup \partial E_n) \to 0. \quad (5.64) \]

This can be seen by considering an expanding ball around any point in \( E_n^c \setminus A_n \). More precisely, for any \( x \in E_n^c \setminus A_n \), define the quantity
\[ r(x) := \inf \{ r > 0 : B_r(x) \cap (\partial A_n \cup \partial E_n) \neq \emptyset \} \in [0, \infty). \]

For all \( x \in E_n^c \setminus A_n \), we have
\[ \text{dist}(x, \partial A_n \cup \partial E_n) = r(x) \quad \text{and} \quad B_{r(x)}(x) \subseteq E_n^c \setminus A_n. \]

Note that we consider that \( B_0(x) = x \). The set \( E_n^c \setminus A_n \) is compact so we can define
\[ r_n := \sup_{x \in E_n^c \setminus A_n} r(x) < \infty \]
and there exists \( x_n \in E_n^c \setminus A_n \) such that \( r_n = r(x_n) \). The limit (5.62), combined with the fact that \( B_{r_n}(x_n) \subseteq E_n^c \setminus A_n \), yields
\[ \mu_{\text{leb}}(B_{r_n}(x_n)) \leq \mu_{\text{leb}}(E_n^c \setminus A_n) \to 0 \]
which implies that \( r_n \to 0 \). (5.64) is obtained by applying the inclusions (5.61) to get
\[
\sup_{x \in \partial \Omega_n} \text{dist}(x, \partial A_n \cup \partial E_n) \leq \sup_{x \in E_n^c \setminus \tilde{A}_n} \text{dist}(x, \partial A_n \cup \partial E_n) \\
\leq \max \left\{ \frac{\sqrt{d}}{n}, \sup_{x \in E_n^c \setminus \tilde{A}_n} \text{dist}(x, \partial A_n \cup \partial E_n) \right\} \\
= \max \left\{ \frac{\sqrt{d}}{n}, r_n \right\} \to 0,
\]
where the second inequality holds because any point in \( A_n \setminus \tilde{A}_n \) is at most a distance \( \sqrt{d}/n \) from \( \partial A_n \).

Combining the limits (5.57) and (5.58) gives
\[ d_H(\partial \Omega, \partial A_n \cup \partial E_n) \to 0 \quad (5.65) \]
and
\[ d_H(\partial A_n, \partial E_n) \to 0. \] (5.66)

Furthermore, we claim that
\[ \sup_{x \in \partial A_n \cup \partial E_n} \text{dist}(x, \partial O_n) \to 0. \] (5.67)

This can be seen by considering length minimising lines between \( \partial \tilde{A}_n \) and \( \partial E_n \). More precisely, let \( x \in \partial E_n \) and let \( y = y(x) \in \partial \tilde{A}_n \) be such that \( |x - y| = \text{dist}(x, \partial \tilde{A}_n) \). The straight line connecting \( x \) and \( y \) must intersect \( \partial O_n \) since one end is in \( O_n \) and the other is in \( O_n^c \). This fact implies that
\[
\sup_{x \in \partial E_n} \text{dist}(x, \partial O_n) \leq \sup_{x \in \partial A_n} \text{dist}(x, \partial \tilde{A}_n) \\
\leq \sup_{x \in \partial A_n} \text{dist}(x, \partial A_n) + d_H(\partial A_n, \partial \tilde{A}_n) \to 0
\]

where the limit holds by (5.66) and (5.60). It can be similarly seen that
\[ \sup_{x \in \partial A_n} \text{dist}(x, \partial O_n) \to 0. \]
giving us (5.67). The limits (5.64) and (5.67) prove that \( d_H(\partial \tilde{O}_n, \partial A_n \cup \partial E_n) \to 0 \) which, combined with (5.65), gives \( d_H(\partial \tilde{O}_n, \partial \tilde{O}_n) \to 0 \).

By (5.57), (5.58) and regularity of \( \tilde{O}_n \),
\[ d_H(A_n, \tilde{O}_n) \to 0 \quad \text{and} \quad d_H(E_n^c, \tilde{O}_n) \to 0 \] (5.68)
so, in particular, \( d_H(A_n, E_n^c) \to 0 \). Using this combined with the inclusions (5.61) and inequality (5.60) for \( d_H(A_n, \tilde{A}_n) \), we have
\[ d_H(E_n^c, \tilde{O}_n) = \sup_{x \in E_n^c} \text{dist}(x, \tilde{O}_n) \leq \sup_{x \in E_n^c} \text{dist}(x, \tilde{A}_n) \to 0. \]

Combining this with the second limit in (5.68), shows that \( d_H(\tilde{O}_n, \tilde{O}_n) \to 0 \), completing the proof.

5.5 Arithmetic algorithms for the spectral problem

In this section we study the computability of the Dirichlet spectrum. Subsections 5.5.1 and 5.5.2 are devoted to the proof of Theorem 5.15, whereas Section 5.5.3 provides a
counterexample that proves Proposition 5.14. We begin with the study of generalised matrix eigenvalue problems which arise naturally from finite element approximations.

5.5.1 Matrix pencil eigenvalue problem

Recall that a matrix pencil eigenvalue problem takes the form:

$$\text{Find } u \in \mathbb{C}^N \text{ and } \lambda \in \mathbb{C} \text{ such that } Au = \lambda Bu.$$ 

First, we show that there exists a family of arithmetic algorithms capable of solving such problems to arbitrary specified precision, restricting ourselves to the case where $A$ and $B$ are real, symmetric and $B$ is positive definite. Let

$$\Omega_{\text{mat},M} := \left\{ (A,B) \in (\mathbb{R}^{M \times M})^2 : A, B \text{ symmetric, } B \text{ positive definite} \right\},$$

$$\Lambda_{\text{mat},M} := \{(A,B) \mapsto A_{j,k} : A_{j,k} \text{ matrix element of } A\} \cup \{(A,B) \mapsto B_{j,k} : B_{j,k} \text{ matrix element of } B\},$$

and

$$\Lambda_{\text{mat},M}^\varepsilon := \Lambda_{\text{mat},M} \cup \{(A,B) \mapsto \varepsilon\}.$$ 

Applying a-posteriori bounds of Oishi [111] for the matrix eigenvalue problem gives the following family of arithmetic algorithms:

Lemma 5.43. For each $\varepsilon > 0$ and $m \in \mathbb{N}$, there exists an arithmetic algorithm $\Gamma_{\text{mat},M}^\varepsilon : \Omega_{\text{mat},M} \to \mathbb{R}^M$ with input $\Lambda_{\text{mat},M}^\varepsilon$, such that

$$|\Gamma_{\text{mat},M}^\varepsilon(A,B)_k - \lambda_k| \leq \varepsilon \text{ for all } (A,B) \in \Omega_{\text{mat},M} \text{ and } k \in \{1, \ldots, M\},$$

where $\lambda_k$ denotes the $k^{th}$ eigenvalues of the matrix pencil $(A,B)$ and $\Gamma_{\text{mat},M}^\varepsilon(A,B)_k$ denotes the $k^{th}$ component of $\Gamma_{\text{mat},M}^\varepsilon(A,B)$.

Proof. Since $\Lambda_{\text{mat},M}^\varepsilon$ is a finite set, we can define the information available to the (arithmetic) algorithm $\Gamma_{\text{mat},M}^\varepsilon$ as $\Lambda_{\Gamma_{\text{mat},M}^\varepsilon}(A,B) = \Lambda_{\text{mat},M}^\varepsilon$. By Gaussian elimination, the matrix elements of $B^{-1}$ can be computed with a finite number of arithmetic operations. Then the eigenvalues of the matrix pencil $(A,B)$ are exactly the eigenvalues $(\lambda_k)_{k=1}^M$ of $E := B^{-1}A$ and the matrix elements of $E$ are accessible to the algorithm.

By the Jacobi eigenvalue algorithm (cf. [125]) there exists a family of approximations $(\tilde{\lambda}_k^m, \tilde{x}_k^m) \in \mathbb{R} \times \mathbb{R}^M$, $k \in \{1, \ldots, M\}, m \in \mathbb{N}$, such that $(\tilde{\lambda}_k^m, \tilde{x}_k^m)$ can be computed
with finitely many arithmetic operations and

\[ \| P^T_m D_m P_m - E \|_F + \| P^T_m P_m - I \|_F \to 0 \quad \text{as} \quad m \to \infty \]  

(5.69)

where

\[ D_m := \text{diag}(\tilde{\lambda}^1_m, \ldots, \tilde{\lambda}^M_m) \quad \text{and} \quad P_m := (\tilde{x}_1^m, \ldots, \tilde{x}_M^m). \]

Here, \( \| \cdot \|_F \) denotes the Frobenius matrix norm. By [111, Theorem 2],

\[ |\lambda_k - \tilde{\lambda}_k^m| \leq |\tilde{\lambda}_k^m| \| P^T_m P_m - I \|_F + \| P^T_m D_m P_m - E \|_F =: \delta_k(m) \]

for all \( k \in \{1, \ldots, M\} \). Let \( m(\varepsilon) \) denote the smallest positive integer such that \( \delta_k(m(\varepsilon)) \leq \varepsilon \) for all \( k \in \{1, \ldots, M\} \). \( m(\varepsilon) \) can be determined by the algorithm since, for each \( m \), \( \delta_k(m) \) can be computed in finitely many arithmetic operations. The proof is completed by letting

\[ \Gamma_{\text{mat},M}(A,B) := (\tilde{\lambda}_k^m(\varepsilon))_{k=1}^M. \]

5.5.2 Algorithm for computing Laplacian eigenvalues

Next, we show that there exists a family of arithmetic algorithms capable of computing, to arbitrary specified precision, the spectrum of the Dirichlet Laplacian on domains of the form

\[ \mathcal{U} = \text{int} \left( \bigcup_{j=1}^N \left( x_j + \left[ -\frac{1}{2n}, \frac{1}{2n} \right]^2 \right) \right) \]  

(5.70)

with \( n, N \in \mathbb{N} \) and \( (x_1, \ldots, x_N) \in (\mathbb{Z}_n^2)^N \). Let

\[ \Omega_{\text{pix},n} := \{ \mathcal{U} \subset \mathbb{R}^2 : \exists N \in \mathbb{N} \text{ and } (x_1, \ldots, x_N) \in (\mathbb{Z}_n^2)^N \text{ such that (5.70) holds} \}, \]

\[ \Lambda_{\text{pix},n} := \{ \mathcal{U} \mapsto \chi_{\mathcal{U}}(x) : x \in \mathbb{Z}_n^2 \}, \]

and

\[ \Lambda_{\text{pix},n}^\varepsilon := \Lambda_{\text{pix},n} \cup \{ \mathcal{U} \mapsto N(\mathcal{U}) \} \cup \{ \mathcal{U} \mapsto \varepsilon \}, \]  

(5.71)

where \( N(\mathcal{U}) := |\mathcal{U} \cap \mathbb{Z}_n^2| \) denotes the number of “pixels” that make up \( \mathcal{U} \). The results of Liu and Oishi [100] combined with Lemma 5.43 yield the following:

**Lemma 5.44.** Let \( n \in \mathbb{N} \) be fixed. For each \( \varepsilon > 0 \), there exists an arithmetic algorithm \( \Gamma_{\text{pix},n}^\varepsilon : \Omega_{\text{pix},n} \to \text{cl}(\mathbb{C}) \) with input \( \Lambda_{\text{pix},n}^\varepsilon \), such that

\[ d_{AW}(\Gamma_{\text{pix},n}^\varepsilon(\mathcal{U}), \sigma(\mathcal{U})) \leq \varepsilon \quad \text{for all} \quad \mathcal{U} \in \Omega_{\text{pix},n}. \]

Proof. First, we fix a finite subset \( \Lambda_{\Gamma_{\text{pix,n}}} (\mathcal{U}) \subset \Lambda_{\text{pix,n}}^\epsilon \) which defines the information available to the (arithmetic) algorithm \( \Gamma_{\text{pix,n}} \), which we aim to construct. Choose

\[
\Lambda_{\Gamma_{\text{pix,n}}} (\mathcal{U}) := \{ \mathcal{U} \mapsto \chi_{\mathcal{U}}(x) : x \in \mathbb{Z}_n^2 \cap \overline{B}_{\kappa(\mathcal{U})}(0) \} \cup \{ \mathcal{U} \mapsto N(\mathcal{U}) \} \cup \{ \mathcal{U} \mapsto \epsilon \},
\]

where \( \kappa(\mathcal{U}) \) is defined as the smallest positive integer such that \( | \mathcal{B}_{\kappa}(\mathcal{U})(0) \cap \mathcal{U} \cap \mathbb{Z}_n^2| = N(\mathcal{U}) \). The consistency hypothesis (cf. Definition 5.9) holds because \( \kappa(\mathcal{U}) \) can be computed with a finite number of arithmetic computations from subsets of \( \{ f(\mathcal{U}) : f \in \Lambda_{\Gamma_{\text{pix,n}}} (\mathcal{U}) \} \). With this choice, the algorithm has access to the list \( (x_1, \ldots, x_N) \in (\mathbb{R}^2)^N \) for which (5.70) holds.

Using this list, we can construct, for each \( m \in \mathbb{N} \), a uniform triangulation \( \mathcal{T}_m \) of \( \mathcal{U} \) such that the elements of \( \mathcal{T}_m \) have diameter \( \sqrt{2}/(n2^m) =: \sqrt{2} h \) (cf. Figure 5.9). Let \( V^m \subset H^1_0(\mathcal{U}) \) denote the piecewise-linear continuous finite element space for the triangulation \( \mathcal{T}_m \). Let \( \{ \phi_j^m \}_{j=1}^{M_0} \) denote the basis of ‘hat’ functions for \( V^m \), where \( M_0 := \dim(V^m) \). Let \( \{ \lambda_k \}_{k=1}^\infty \) denote the Dirichlet eigenvalues of the domain \( \mathcal{U} \), ordered such that \( \lambda_k \leq \lambda_{k+1} \) for all \( k \in \mathbb{N} \).

The Ritz-Galerkin finite element approximations for \( \{ \lambda_k \}_{k=1}^\infty \) are the eigenvalues \( \{ \lambda_k^m \}_{k=1}^{M_0} \), \( m \in \mathbb{N} \), of the matrix pencil \( (A^m, B^m) \), where the matrix elements of the matrices \( A^m \) and \( B^m \) read

\[
A_{j,k}^m := \langle \nabla \phi_j^m, \nabla \phi_k^m \rangle_{L^2(\mathcal{U})} \quad \text{and} \quad B_{j,k}^m := \langle \phi_j^m, \phi_k^m \rangle_{L^2(\mathcal{U})} \quad (j, k \in \{1, \ldots, M_0\})
\]

respectively. These matrix elements can be computed from the information \( (x_1, \ldots, x_N) \), \( n \) and \( m \) with a finite number of arithmetic computations. Note that \( A \) and \( B \) are symmetric and \( B \) is positive definite.

In [100], the authors introduce a quantity

\[
q^m := l^m + (C_0/n2^m)^2,
\]

where,
5.5 Arithmetic algorithms for the spectral problem

- \( C_0 > 0 \) can be bounded above by an explicit expression [100, Section 2] and,

- \( l^m \) is the maximum eigenvalue of a matrix pencil \((D^m, E^m)\) [100, eq. (3.22)].

Here, the matrix elements of \( D^m \) and \( E^m \) are explicitly constructed from inner products between overlapping basis functions of piecewise-linear finite element spaces on \( T^m \) and hence can be computed with a finite number of arithmetic computations on \((x_1, \ldots, x_N), n \) and \( m \). Also, \( E^m \) is diagonal and positive definite.

By [100, Remark 3.3], it holds that \( q^m \to 0 \) as \( m \to \infty \). [100, Theorem 4.3] states that, for each \( m \in \mathbb{N} \) and each \( k \in \{1, \ldots, M_0\} \), if \( q^m \lambda^m_k < 1 \), then

\[
\frac{\lambda^m_k}{(1 + \lambda^m_k q^m)} \leq \lambda^m_k \leq \lambda^m_k.
\]  

(5.72)

Since the matrix elements of \( A^m, B^m, D^m \) and \( E^m \) are available to the algorithm \( \Gamma^e_{\text{pix},n} \), by Lemma 5.43, the approximations

\[
\lambda^m_k, \delta := \Gamma^\delta_{\text{mat},M_0}(A^m, B^m)
\]

and

\[
q^m := \Gamma^\delta_{\text{mat},M_0}(D^m, E^m)
\]

are also available to \( \Gamma^e_{\text{pix},n} \), for any \( \delta > 0 \). These approximations provide upper and lower bounds for \( \lambda^m_k \) and \( q^m \)

\[
\lambda^m_k \in [\lambda^m_k - \delta, \lambda^m_k + \delta], \quad q^m \in [q^m - \delta, q^m + \delta].
\]  

(5.73)

We claim that if \((M, m, \delta) \in \mathbb{N} \times \mathbb{N} \times \mathbb{R}_+ \) is such that \( (\lambda^m_M + \delta)(q^m + \delta) < 1 \), then

\[
d_{AW} \left( \{\lambda^m_k\}_{k=1}^M, \sigma(\mathcal{V}) \right) \leq \delta + \varepsilon_1(M, m, \delta) + \varepsilon_2(M, m, \delta) \]  

(5.74)

where

\[
\varepsilon_1(M, m, \delta) := \max \left\{ (q^m + \delta)(\lambda^m_k + \delta)^2/(1 + (q^m + \delta) + (\lambda^m_k - \delta), k \in \{1, \ldots, M\} \right\}
\]

and

\[
\varepsilon_2(M, m, \delta) := 2^{-(\lambda^m_M + \delta)/2 + 1}.
\]

To see this, first note that, using the formula

\[
d_{AW}(A, B) \leq d_H(A, B) \quad (A, B \subset \mathbb{C} \text{ bounded}),
\]
we have

\[
\delta + \sum_{j=1}^{[\delta]} 2^{-j} \min \left\{ 1, \sup_{|x| \leq j} \left| \text{dist}(x, \{\lambda_k^m\}_{k=1}^\infty) - \text{dist}(x, \{\lambda_k^M\}_{k=1}^\infty) \right| \right\} + \sum_{j=\delta}^\infty 2^{-j}.
\]

(5.75)

Since \text{dist}(x, \{\lambda_k^\infty\}_{k=1}^\infty) = \text{dist}(x, \{\lambda_k^M\}_{k=1}^\infty) for \ |x| \leq |\lambda_M|, the second term on the right hand side of (5.75) is bounded by

\[
d_{AW}(\{\lambda_k^m\}_{k=1}^M; \{\lambda_k^M\}_{k=1}^M) \leq \text{d}_{H}(\{\lambda_k^m\}_{k=1}^M; \{\lambda_k^M\}_{k=1}^M)
\]

\[
\leq \max\{|\lambda_k^m - \lambda_k^M|: k \in \{1, \ldots, M\}\} \leq \epsilon_1(\delta, M, m)
\]

where the final inequality follows from (5.72) and (5.73). Applying (5.72) and (5.73) again and noting that the condition \((\lambda_M^{m, \delta} + \delta)(q^m, \delta + \delta) < 1\) ensures that \(\lambda_M^{m, \delta} q^m \leq 1\), we have

\[
\sum_{j=\delta}^\infty 2^{-j} \leq 2^{-\lambda_M+1} \leq 2^{-\lambda_M^m/2+1} \leq \epsilon_2(M, \delta, m),
\]

bounding the third term on the right hand side of (5.75) and proving (5.74).

Let \(\delta(M) := 1/M\). Define \(m(M)\) as the smallest \(m \in \mathbb{N}\) such that

\[
(q^m, \delta(M)) (\lambda_M^{m, \delta(M)} + \delta(M))^2 \leq 1/M.
\]

Then, \(\epsilon_1(M, m(M), \delta(M)) \leq 1/M\). For each \(M \in \mathbb{N}\), \(m(M)\) can be determined by the algorithm since it can compute the quantities \(q^m, \delta(M)\) and \(\lambda_M^{m, \delta(M)}\). Define \(M(\epsilon)\) as the smallest positive integer such that

\[
\delta \circ M(\epsilon) + \epsilon_1(M(\epsilon), m \circ M(\epsilon), \delta \circ M(\epsilon)) + \epsilon_2(M(\epsilon), m \circ M(\epsilon), \delta \circ M(\epsilon)) \leq \epsilon,
\]

where \(m \circ M(\epsilon) = m(M(\epsilon))\) and \(\delta \circ M(\epsilon) = \delta(M(\epsilon))\). For each \(\epsilon > 0\), \(M(\epsilon)\) can be determined by the algorithm since \(\epsilon_1\) and \(\epsilon_2\) can be computed. The proof of the lemma is completed by letting

\[
\Gamma_{\text{pix,n}}^\epsilon(\mathcal{U}) := \left\{ \lambda_k^{m \circ M(\epsilon), \delta \circ M(\epsilon)} \right\}_{k=1}^{M(\epsilon)}.
\]

(5.76)

\[\square\]

**Remark 5.45.** The results of [100] are formulated for connected domains only. While this assumption is not necessarily satisfied for domains in \(\Omega_{\text{pix,n}}\), the results from [100] can be applied to every connected component of a set \(\mathcal{U} \in \Omega_{\text{pix,n}}\) separately. This is
justified, because the Dirichlet spectrum of $U$ is simply the union of the Dirichlet spectra of all connected components of $U$. Moreover, any $U \in \Omega_{\text{pix},n}$ consists of only finitely many connected components, which can be determined in a finite number of steps from the information given in $\Lambda_{\text{pix},n}$.

We have shown that the Dirichlet spectrum of an arbitrary (but fixed) pixelated domain from $\Omega_{\text{pix},n}$ is computable via an arithmetic algorithm. It remains to pass from pixelated domains to arbitrary domains in $\Omega_1$ (recall (5.16)). To this end, we combine the Mosco convergence results from Section 5.4.2 with the following proposition.

**Proposition 5.46.** Let

$$\Omega_M := \{ \partial \subset \mathbb{R}^2 : \partial \text{ open, bounded and } \partial_n \xrightarrow{M} \partial \text{ where } \partial_n \text{ pixelated domains for } \partial \}.$$  

Then there exists a sequence of arithmetic algorithms $\Gamma_n : \Omega_M \to \text{cl}(\mathbb{C}), n \in \mathbb{N}$, with input $\Lambda_0$ such that

$$d_{AW}(\Gamma_n(\partial), \sigma(\partial)) \to 0 \quad \text{as} \quad n \to \infty \quad \text{for all} \quad \partial \in \Omega_M.$$  

**Proof.** Let $\partial \in \Omega_M$. Let $\partial_n \subset \mathbb{R}^2, n \in \mathbb{N}$, denote the corresponding pixelated domains (cf. Definition 5.16).

We shall construct a family of (arithmetic) algorithms $\Gamma_n : \Omega_1 \to \text{cl}(\mathbb{C})$ with input $\Lambda_0$. First, we define the information available to each algorithm $\Gamma_n$, by fixing a finite subset $\Lambda_{\Gamma_n} \subset \Lambda_0$. Let

$$\Lambda_{\Gamma_n} := \{ \partial \mapsto \chi_{\partial}(x) : x \in \mathbb{Z}_n^2 \text{ with } |x| \leq n \},$$

so that the algorithm $\Gamma_n$ has access to the set $\{x_1, ..., x_N\} := \partial \cap B_n(0) \cap \mathbb{Z}_n^2$.

Let

$$\tilde{\partial}_n := \text{int} \left( \bigcup_{j=1}^{N} \left( x_j + \left[ -\frac{1}{2n^2}, \frac{1}{2n^2} \right]^2 \right) \right).$$

It holds that $\tilde{\partial}_n \in \Omega_{\text{pix},n}$ for each $n$ and, since $\partial$ is bounded, $\tilde{\partial}_n = \partial_n$ for all sufficiently large $n$. Hence using the hypothesis that $\partial_n \xrightarrow{M} \partial$, $\tilde{\partial}_n$ converges to $\partial$ in the Mosco sense as $n \to \infty$. By Lemma 5.2,

$$d_{AW}(\sigma(\tilde{\partial}_n), \sigma(\partial)) \to 0 \quad \text{as} \quad n \to \infty.$$  

Since $\tilde{\partial}_n$ is defined entirely by $\Lambda_{\Gamma_n}$, we can define

$$\Gamma_n(\partial) = \Gamma_{\text{pix},n}^{1/n}(\tilde{\partial}_n)$$
for each \( n \in \mathbb{N} \). Note that the consistency property Definition 5.9 (ii) holds trivially since \( \Lambda_{\Gamma_n} \) does not depend on \( \partial \mathcal{O} \). The proposition is proved by the fact that

\[
\text{d}_{\text{AW}} \left( \Gamma_{\text{pix},n}^{1/n}(\partial_n), \sigma(\partial) \right) \leq \text{d}_{\text{AW}} \left( \Gamma_{\text{pix},n}^{1/n}(\partial_n), \sigma(\tilde{\partial}_n) \right) + \text{d}_{\text{AW}} \left( \sigma(\tilde{\partial}_n), \sigma(\partial) \right) \leq \frac{1}{n} + o(1) \rightarrow 0 \quad \text{as} \quad n \rightarrow \infty.
\]

(5.77)

Theorem 5.15 now follows by combining Proposition 5.46 with Theorem 5.3 and Proposition 5.42.

Remark 5.47. From the perspective of the SCI hierarchy it is natural to ask whether any finer classification might be possible, specifically in terms of explicit error bounds. This remains an open question and it is clear that our method cannot yield any explicit error bounds for general domains in \( \Omega_1 \). This is perhaps most clearly demonstrated in the final error bound (5.77). The behaviour \( \text{d}_{\text{AW}}(\sigma(\partial_n), \sigma(\partial)) = o(1) \) on the right hand side of (5.77) was deduced from the Mosco convergence \( \partial_n \xrightarrow{\text{Mosco}} \partial \), for which no uniform convergence rate can be expected in general.

While the question remains open, the fact that no uniform regularity assumption (such as Hölder continuity with fixed exponent) was made on \( \partial \mathcal{O} \) suggests that no explicit error bound is possible.

5.5.3 Counter-example

In this section we give a counterexample showing that if the regularity assumptions on the domain are relaxed too much, computability fails to be true, i.e. the Dirichlet spectrum cannot be computed by a single sequence of algorithms anymore and at least two limits are necessary. Proposition 5.14 follows immediately from the following result.

Proposition 5.48. Let \( \Gamma_n : \Omega_0 \rightarrow \mathcal{M}, n \in \mathbb{N} \), be any family of arithmetic algorithms with input \( \Lambda_0 \). Then, for any \( \mathcal{O} \in \Omega_0 \) with \( \mu_{\text{H}}(\partial \mathcal{O}) = 0 \) and any \( \varepsilon > 0 \), there exists \( \partial_\varepsilon \in \Omega_0 \) with \( \partial_\varepsilon \subseteq \mathcal{O} \) and \( \mu_{\text{H}}(\partial_\varepsilon) \leq \varepsilon \) such that \( \Gamma_n(\mathcal{O}) = \Gamma_n(\partial_\varepsilon) \) for all \( n \) and, for sufficiently small \( \varepsilon > 0 \), \( \sigma(\partial) \neq \sigma(\partial_\varepsilon) \).

Proof. Let \( \Gamma_n \) be as hypothesised, let \( \varepsilon > 0 \) and let \( \partial \in \Omega_0 \). Define the geometric quantity

\[
r_{\text{int}}(\partial) := \sup \{ r > 0 : \exists \text{ square } [s, s+r] \times [t, t+r] \subset \partial \}.
\]
Openness of $\mathcal{O}$ implies that $r_{\text{int}}(\mathcal{O}) > 0$. For any fixed $n$, $\Gamma_n(\mathcal{O})$ depends only on finitely many values of $\chi_\mathcal{O}(x)$, say $x_1^n, \ldots, x_{k_n}^n$. We assume without loss of generality that the set $\{x_1^n, \ldots, x_{k_n}^n\}$ is growing with $n$, i.e. that, for all $n$,

$$\{x_1^n, \ldots, x_{k_n}^n\} \subset \{x_1^{n+1}, \ldots, x_{k_{n+1}}^{n+1}\} \quad \text{and} \quad x_j^n = x_j^{n+1}, \quad j = 1, \ldots, k_n. \quad (5.78)$$

Thus, we may drop the superscript $n$ and merely write $\{x_1, \ldots, x_{k_n}\}$. Let us denote by $\{y_1, \ldots, y_{k_n}\}$ the subset of points for which $\chi_\mathcal{O}(y_j) = 1$. Now, define a new domain $\mathcal{O}_\varepsilon$ as follows. For $t > 0$ define the strips $S^k_\varepsilon := \left(\left((y_k)_1 - \frac{t}{2}, (y_k)_1 + \frac{t}{2}\right) \times \mathbb{R}\right) \cap \mathcal{O}$. Next, let

$$\mathcal{O}_\varepsilon^n := \bigcup_{k=1}^{l_n} S^k_{2^{-k}\varepsilon} \quad \text{and} \quad \mathcal{O}_\varepsilon := \left(\bigcup_{n=1}^{\infty} \mathcal{O}_\varepsilon^n\right) \cup \partial^\varepsilon \mathcal{O} \quad (5.79)$$

where, recall that $\partial^\varepsilon \mathcal{O} = \{x \in \mathcal{O} : \text{dist}(x, \partial \mathcal{O}) < \varepsilon\}$. Note that, by (5.78), we have

$$\mathcal{O}_\varepsilon^n \subset \mathcal{O}_\varepsilon^{n+1} \quad (5.80)$$

for all $n$. Note also that $\mathcal{O}_\varepsilon$ is bounded, open and connected for any $\varepsilon > 0$. One has $\chi_\mathcal{O}(x_k) = \chi_{\mathcal{O}_\varepsilon}(x_k)$ for all $k \in \{1, \ldots, k_n\}$ and all $n \in \mathbb{N}$, and therefore, by consistency of algorithms (cf. Definition 5.9 (ii)), $\Gamma_n(\mathcal{O}_\varepsilon) = \Gamma_n(\mathcal{O})$ for all $n \in \mathbb{N}$.

However, it is easily seen from the min-max principle that for the lowest eigenvalue $\lambda_1(\mathcal{O})$, of $-\Delta_\mathcal{O}$, one has

$$\lambda_1(\mathcal{O}) \leq \frac{\pi^2}{r_{\text{int}}(\mathcal{O})^2},$$

Next, we use Poincaré’s inequality [75, eq. (7.44)] to get

$$\|u\|_{L^2(\mathcal{O}_\varepsilon)} \leq C \mu_{\text{leb}}(\mathcal{O}_\varepsilon)^\frac{1}{2} \|\nabla u\|_{L^2(\mathcal{O}_\varepsilon)} \leq C \left(\mu_{\text{leb}}(\partial^\varepsilon \mathcal{O}) + \sum_{k=1}^{\infty} 2^{-k} \varepsilon \text{diam}(\mathcal{O})\right)^\frac{1}{2} \|\nabla u\|_{L^2(\mathcal{O}_\varepsilon)}$$

for some constant $C > 0$ independent of $\varepsilon$ and all $u \in H^1_0(\mathcal{O}_\varepsilon)$, where in the second inequality, we used the expression (5.79) for $\mathcal{O}_\varepsilon$. Since $\mu_{\text{leb}}(\partial^\varepsilon \mathcal{O}) \to 0$ as $\varepsilon \to 0$ by continuity of measures, we conclude using the min-max principle that $\lambda_1(\mathcal{O}_\varepsilon) \to \infty$ as $\varepsilon \to 0$ and hence $\sigma(\mathcal{O}) \neq \sigma(\mathcal{O}_\varepsilon)$ for small enough $\varepsilon > 0$. \hfill \Box

**Remark 5.49.** The counterexample in the proof of Proposition 5.48 is pathological in the sense that the complement of the domain $\mathcal{O}_\varepsilon$ may have infinitely many connected components. This is not crucial. Indeed, one can easily construct a counterexample
Figure 5.10 The set $\mathcal{O}$ (left) and pixelated domain $\mathcal{O}_n$ for $n = 20$ and $h = 1/n$ (right).

Figure 5.11 Approximations of lowest eigenvalue for different values of $h = 2^{-m}$ and $n$.

whose complement has only one connected component: Let $\mathcal{O} = (0, 1)^2$ be the unit square and

$$\mathcal{O}_\varepsilon := \left( \bigcup_{n=1}^{\infty} \bigcup_{k=1}^{k_n} S_{2^{-k\varepsilon}} \right) \cup \left( (0, 1) \times (0, \varepsilon) \right),$$

with the notation from the previous proof. Then $\Gamma_n(\mathcal{O}_\varepsilon) = \Gamma_n(\mathcal{O})$ for all $n$ and $\sigma((0, 1)^2) \neq \sigma(\mathcal{O}_\varepsilon)$ for sufficiently small $\varepsilon > 0$ while $\mathcal{O}_\varepsilon^c$ is connected.

### 5.6 Numerical Results

In this section we illustrate the abstract ideas from the previous sections with a concrete numerical example. The closure of the domain we study belongs to the class of filled Julia sets described in Example 5.5 hence the pixelation approximations converge in the Mosco sense and the sequence of arithmetic algorithms constructed in Section 5.5.2 converge in the Attouch-Wets metric. Numerical experiments for the Laplacian on filled Julia sets were also recently performed in [134].
5.6 Numerical Results

Figure 5.12 Double logarithmic plot of relative differences $|\lambda_0^{m+1} - \lambda_0^m|$ for $n \in \{20, 40, 80, 160\}, m \in \{0, \ldots, 160/n\}$.

Figure 5.13 Selected approximated eigenfunctions of $\mathcal{O}$ for $n = 100, h = 1/n$ (normalised such that $v_i^T B^m v_i = 1$).

We consider the filled Julia set $K$ defined by

$$K = \{z \in \mathbb{C} : |f^{2n}(z)| \leq 2 \forall n \in \mathbb{N}\}, \quad \text{where} \quad f(z) = z^2 + \frac{\sqrt{5} - 1}{2}.$$

It can be shown that $K$ has a fractal boundary (cf. [101]). Mandelbrot suggested the name “San Marco Set” for $K$, because it resembles the Basilica of Venice together with its reflection in a flooded piazza (see Figure 5.10).
We implemented a finite element method on subsequent pixelated domains for $\mathcal{O} = \text{int}(K)$ and computed approximations to the lowest eigenvalue with increasingly fine meshes. To be more precise, for $n \in \{20, 40, 80, 160\}$ we approximated lowest eigenvalue $\lambda_n^m$ of $-\Delta_{\mathcal{O}_n}$ for meshes $\mathcal{T}^m$ with $m \in \{0, 1, \ldots, 160\}$ (or equivalently $h \in \{2^{-m}n^{-1} : m \in \{0, \ldots, 160\}\}$, recall Section 5.5.2).

Because our emphasis is theoretical, implementing the full a-posteriori error computation of [100] would be beyond the scope of the current work. Instead, the approximation to the lowest eigenvalue in each case was computed using the Rayleigh-Ritz method for the pair $(A^m, B^m)$ of stiffness and mass matrix: the Rayleigh quotient $$(v^\top A^m v) / (v^\top B^m v)$$ was minimised via a straightforward gradient descent method. The gradient descent was iterated until the derivative of the Rayleigh quotient was less than $10^{-10}$. The results are shown in Figures 5.11 and 5.12. The data points in Figure 5.11 suggest that for each fixed $n$ the refinement of the mesh leads to a convergent sequence of approximations.

The decay of the successive differences between the $\lambda_n^m$ in Figure 5.12 suggests a convergence rate of approximately $1.33 \approx 2 \cdot \frac{2}{7}$, which is in accordance with the regularity of the pixelated domain, which has reentrant corners of angle $\frac{3}{2}\pi$ (cf. [6]). Figure 5.12 also suggests a worsening of the convergence rate if both $n$ and $h$ are increased simultaneously. This is reflected in the fact that the lines in Figure 5.12 move to the left as $n$ increases. This degradation of the convergence rate is to be expected as to the rough boundary of $\mathcal{O}$ is better and better approximated by $\mathcal{O}_n$ as $n$ increases.

For triangulations which are not prohibitively fine, also the approximations of higher eigenvalues and eigenfunctions can be computed. Figure 5.13 shows 6 selected approximated eigenfunctions $v_1, v_2, v_8, v_{16}, v_{95}$ and $v_{99}$ for $n = 100$, $h = n^{-1}$ (i.e. $m = 0$). The approximations are normalised such that $v_i^\top B^m v_i = 1$, where $B^m$ is the mass matrix associated with $\mathcal{T}^m$.
