18 **Funding sources:** This study was funded by the International Alliance of Dermatology  
19 Patient Organizations (GlobalSkin) as part of its Global Research on the Impact of  
20 Dermatological Diseases (GRIDD) project. GlobalSkin is a not-for-profit alliance of  
21 dermatology patient organisations worldwide. Participants were recruited through  
22 GlobalSkin's network of patient organisations.

23 **Conflict of interests:** The authors report no conflicts of interest in this work.

24 **Data availability:** The data underlying this article will be shared on reasonable request to  
25 the corresponding author.

1 **Ethics statement:** Ethical approval was obtained from Cardiff University School of  
2 Healthcare Sciences Ethics Committee (SREC:826). Informed consent was obtained from all  
3 participants.

4

5

## 6 **What is already known about this topic?**

- 7 • No existing dermatology-specific patient-reported outcome measure (PROM) is  
8 recommended for use according to the COSMIN criteria.
- 9 • The conceptual framework of the impact of dermatological conditions on patients'  
10 lives depicts 'impact' as a multifaceted construct involving physical, daily life and  
11 responsibilities, psychological, social, and financial impacts.
- 12 • The Patient-Reported Impact of Dermatological Diseases (PRIDD) instrument is in  
13 development with evidence of content validity, acceptability, feasibility.

## 14 **What does this study add?**

- 15 • This study produced the final PRIDD, reduced to 16 items across four domains, for  
16 use in research and clinical practice.
- 17 • The data triangulated and refined the conceptual framework of impact from five to  
18 four domains: physical, life responsibilities, psychological and social impacts.
- 19 • The results provide evidence of PRIDD's structural validity and internal consistency  
20 and further support its content validity.

## 21 **What are the clinical implications of this work?**

- 22 • This validated conceptual framework provides clinicians and researchers with a  
23 valuable framework for understanding and measuring the impact of dermatological  
24 conditions on patients' lives.
- 25 • Clinicians should select high-quality, evidence-based PROMs. PRIDD has good  
26 evidence of content validity, acceptability, feasibility, structural validity, and internal  
27 consistency. The remaining measurement properties (construct validity, test-retest  
28 reliability, measurement error and responsiveness) will be tested in the next and  
29 final step in PRIDD's development.

1

2 **Abstract**

3 **Background:** Existing dermatology-specific patient-reported outcome measures (PROMs) do  
4 not fully capture the substantial physical, psychological, and social impact of dermatological  
5 conditions on patients' lives and are not recommended for use according to the Consensus-  
6 based Standards for the Selection of Health Measurement Instruments (COSMIN) criteria.  
7 Most were developed with insufficient patient involvement and relied on classical  
8 psychometric methods. We are developing the new Patient-Reported Impact of  
9 Dermatological diseases (PRIDD) measure for use in research and clinical practice in  
10 partnership with patients.

11 **Objectives:** To examine the factor structure of PRIDD, determine the definitive selection of  
12 items for each subscale, and establish structural validity and internal consistency through  
13 classical and modern psychometric methods.

14 **Methods:** Two cross-sectional online surveys. Adults ( $\geq 18$  years) worldwide living with a  
15 dermatological condition were recruited through the International Alliance of Dermatology  
16 Patient Organizations' (GlobalSkin) membership network. They completed PRIDD and a  
17 demographics questionnaire via an online survey. We examined missing data and  
18 distribution of scores for each item. The factor structure was assessed using confirmatory  
19 and exploratory factor analysis (Survey 1). Internal consistency was examined using  
20 Cronbach's alpha. Rasch measurement theory analyses were conducted, including iterative  
21 assessment of rating scale function, fit to the Rasch model, unidimensionality, reliability,  
22 local dependence, targeting and differential item functioning (DIF)(Survey 1 and 2).

23 **Results:** 483 and 504 people participated in Survey 1 and 2, respectively. All items had  $\leq 3\%$   
24 missing scores and all five response options were used. A four-factor model showed best fit.  
25 PRIDD and all four subscales were internally consistent but showed some misfit to the Rasch  
26 measurement model. Adjustments were made to rectify disordered thresholds, remove  
27 misfitting items, local dependency and DIF, and improve targeting. The resultant 16-item  
28 version and subscales fit the Rasch model, showed no local dependency or DIF at the test  
29 level, and were well-targeted.

1 **Conclusions:** This field test study produced the final PRIDD consisting of 16 items across four  
2 domains. The data triangulated and refined the conceptual framework of impact and  
3 provide evidence of PRIDD's structural validity and internal consistency. The final step in  
4 PRIDD's development and validation is to test the remaining measurement properties.

ACCEPTED MANUSCRIPT

## 1 Introduction

2 Assessment of the full impact of dermatological conditions on patients' lives is crucial to  
3 effective management. Dermatology-specific (used across dermatological conditions)  
4 patient-reported outcome measures (PROMs) are ideally suited as they are more specific,  
5 sensitive, and clinically sensible than generic PROMs while allowing for use and comparison  
6 across conditions.<sup>1-3</sup>

7 Recent systematic reviews reveal that no dermatology-specific PROMs meet the Consensus-  
8 based Standards for the Selection of Health Measurement Instruments (COSMIN)<sup>4</sup> to be  
9 recommended for use according to their known measurement properties.<sup>5-7</sup> Much of the  
10 issues identified stem from insufficient patient involvement during development and the  
11 methodological limitations of Classical Test Theory (CTT).<sup>5</sup>

12 We are developing the Patient-Reported Impact of Dermatological Diseases (PRIDD)  
13 measure in partnership with patients and using both classic and modern psychometric  
14 methods. PRIDD measures the impact of dermatological conditions on the patient's life and  
15 is for use in research and clinical practice with adults living with any dermatological  
16 condition worldwide.

### 17 Development and validation of PRIDD

18 PRIDD development and validation involves a *content validity* and subsequent *psychometric*  
19 *testing* phase (Figure S1).<sup>4,8-11</sup>

20 The *content validity phase* had three key stages: 1) concept elicitation,<sup>12</sup> 2) participatory  
21 item reduction,<sup>13</sup> and 3) pilot testing.<sup>14,15</sup> The resultant 26-item English version of PRIDD,  
22 with each item rated on a 5-point scale ranging from 0 (never) to 5 (always), has strong  
23 evidence of content validity according to the COSMIN standards.<sup>4</sup> The conceptual  
24 framework of impact followed a reflective model<sup>12</sup> with five domains of impact - physical,  
25 daily life and responsibilities, psychological, social, and financial (Figure S2)<sup>13</sup> - but is yet to  
26 be validated quantitatively.<sup>16</sup>

27 The current *psychometric testing phase* consists of two sequential stages: 4) field testing  
28 and 5) testing of the measurement properties. The field test aims to establish structural  
29 validity, an important measurement property that describes the 'degree to which the scores

1 of an instrument are an adequate reflection of the dimensionality of the construct to be  
2 measured.<sup>17,18</sup> Only once PRIDD is finalised through field testing can its measurement  
3 properties be fully established.

4 Factor analysis, an extension of CTT, and Rasch analysis, part of the Item Response Theory  
5 (IRT) family, are the preferred statistical methods to assess structural validity.<sup>19</sup> Factor  
6 analysis is valuable for identifying the dimensions (or subscales) in a PROM, but cannot  
7 establish the psychometric quality of those dimensions. IRT, a modern psychometric  
8 method, is a powerful tool to assess PROM psychometrics as it overcomes many of the  
9 limitations of CTT. The Rasch model is a unidimensional measurement model that satisfies  
10 the fundamental assumptions of IRT,<sup>20,21</sup> meaning it provides a measurement template  
11 against which scales can be tested.<sup>22</sup>

12 This study (stage 4 of 5) aimed to examine the factor structure of PRIDD, determine the  
13 definitive selection of items for each subscale, and establish structural validity and internal  
14 consistency through classical and modern psychometric methods. Based on the conceptual  
15 framework of impact we hypothesised that PRIDD had five domains.

16

## 17 **Patients and methods**

### 18 **Study design and setting**

19 We conducted two cross-sectional online surveys. Ethical approval was obtained from  
20 Cardiff University School of Healthcare Sciences Ethics Committee (SREC:826). Informed  
21 consent was obtained from all participants.

### 22 **Patients and recruitment**

23 We employed convenience sampling to recruit eligible participants to both surveys through  
24 the International Alliance of Dermatology Patient Organizations' (GlobalSkin) membership  
25 network. GlobalSkin (<https://globalskin.org/>) is a not-for-profit alliance of over 245  
26 dermatology patient organisations worldwide. The samples were independent of each  
27 other. It is best practice to development and validate a PROM in one language with later  
28 cross-cultural translation. PRIDD is initially being developed in English. Participants therefore  
29 met the inclusion criteria if they were an adult ( $\geq 18$  years), living with a dermatological

1 condition, and spoke English sufficient to complete the survey independently. We aimed to  
2 recruit the recommended sample size of 250 – 500 for Rasch analysis to each survey.<sup>23</sup> Non-  
3 participation was due to non-response.

#### 4 **Procedure and materials**

5 Survey 1 was open from 1 November to 1 December 2021; Survey 2 from 29 June to 29 July  
6 2022. Participants were directed to the online platform, which included the participant  
7 information sheet (PIS), consent form, and survey consisting of demographic items and  
8 PRIDD (Appendix S1) and given at least four weeks to respond.

#### 9 **Patient involvement**

10 GlobalSkin conceived of the PRIDD measure, were involved in setting the research priorities  
11 and defining research questions, and provided input into study design, conduct, and  
12 dissemination. Our lead patient co-researchers JA and AF are named co-authors.

#### 13 **Data analysis strategy**

14 We followed the order of data analysis for field testing set out by the COSMIN group and  
15 evaluated the results against their quality criteria for structural validity and internal  
16 consistency.<sup>11,18</sup> We completed all of the steps outlined below on the Survey 1 data. This  
17 revealed that further amendments were required. After adjusting PRIDD, we conducted  
18 Survey 2, where we repeated many aspects of the analysis. We have noted which parts of  
19 the data analysis used which dataset below. We ran multiple iterations of the analysis on  
20 the different versions of PRIDD (Table S1): a analysis of PRIDD V0.1 to V.04 used Survey 1 data  
21 and V.05 and V.1 used Survey 2 data. We used Little's test of Missing Completely at Random  
22 (MCAR) for missing values.<sup>24</sup>

#### 23 **1. Examination of individual PRIDD items (Survey 1 and 2)**

24 The percentage of missing scores was examined for each item using SPSS 27 (IBM, Armonk,  
25 NY, USA). Items with  $\leq 3\%$  missing scores were deemed 'acceptable' and  $\geq 15\%$  not  
26 acceptable.<sup>18</sup> Distributions of item scores were examined using item means ( $\bar{x}$ ) and  
27 standard deviations (SDs).

#### 28 **2. Factor analysis (Survey 1)**

### 1            **a. Confirmatory factor analysis**

2    Confirmatory factor analysis (CFA) is more appropriate than exploratory factor analysis (EFA)  
3    when a conceptual framework is available.<sup>4,18,19,25</sup> We performed a CFA with categorical  
4    factor indicators applying full information maximum likelihood to missing data using Mplus  
5    8.2 (Muthen & Muthen, Los Angeles, CA, USA).<sup>26,27</sup> Mplus determines the number of  
6    categories for each factor indicator with a robust weighted least squares estimator  
7    (wlsmv).<sup>28</sup> Multicollinearity was assessed via bivariate correlations (Spearman's Rho), with  $r$   
8     $\leq 0.8$  deemed acceptable.<sup>29</sup> Goodness-of-fit of all the CFA models (Table 5) was examined  
9    according to the criteria outlined in Table 1. Structural validity was sufficient if CFI or TLI  $>$   
10    0.95, RMSEA  $< 0.06$ , or SRMR  $< 0.08$ .<sup>11</sup>

### 11           **b. Exploratory factor analysis**

12    As the CFA did not support our 5-domain conceptual framework, we performed an EFA with  
13    listwise deletion on SPSS 27 using the Principal Factor Method with oblique rotation (direct  
14    oblimin) to determine the number of dimensions.<sup>18</sup> The Kaiser-Meyer-Olkin (KMO) test  
15    (KMO  $> 0.5$ ) and Bartlett's test of sphericity ( $p < 0.05$ ) were used to confirm the adequacy of  
16    the sample and data, respectively.

17    Four criteria were used to determine the number of factors (see Table 2). As uncertainty  
18    remained regarding the number of factors to extract, we followed Costello and Osborne's<sup>30</sup>  
19    recommendation to run multiple factor analyses, setting the number of factors to retain  
20    manually once at the projected number based on the a priori factor structure, then at the  
21    number of factors suggested by the scree test, and finally at numbers above and below  
22    those numbers. Item loading tables were compared and the solution with the most factors  
23    and 'cleanest' factor structure (item loadings  $> 0.3$ , no or few crossloadings, and no factors  
24    with fewer than 3 items) was deemed to have best fit to the data. Residual correlations  $< 0.1$   
25    and factor loadings  $\geq 0.5$  were deemed acceptable.<sup>31-33</sup>

### 26           **3. Internal consistency (Survey 1 and 2)**

27    We tested internal consistency for PRIDD and each factor separately with listwise deletion  
28    using SPSS 27. Items with inter-item correlations  $> 0.7$  and item-total correlations  $< 0.3$  were

1 candidates for removal. Cronbach's alpha ( $\alpha$ ) > 0.7 was deemed acceptable and > 0.9  
2 indicated item redundancy.<sup>11</sup>

### 3 **4. Rasch analysis (Survey 1 and 2)**

4 Rasch analyses were performed iteratively on PRIDD and each subscale using RUMM2030  
5 (RummLab Pty Ltd., Duncraig, Australia) according to the steps outlined in Table 3.<sup>34</sup> We  
6 tested whether the subscales could be validly combined into an 'overall impact' total score  
7 using the subtest approach to obtain R (average latent correlation between the subscales)  
8 and A values (the amount of shared variance between the subscales).

## 9 **Results**

10 483 (Table 4) patients from 42 countries (Table S3) representing 49 dermatological  
11 conditions (Table S4) participated in Survey 1; 504 from 38 countries with 34 dermatological  
12 conditions in Survey 2. Of these, 703 (71%) were native English speakers (Table S5). PRIDD  
13 missing data were MCAR,  $p > 0.05$ .

### 14 **Examination of PRIDD items**

15 All items had acceptable levels ( $\leq 3\%$ ) of missing scores (Table S6). All item means were close  
16 to the centre of the range of possible scores, indicating that the response options detected  
17 the full range of the construct, were well-worded, and had higher variances.<sup>35</sup>

### 18 **PRIDD V0.1**

19 Bivariate correlations for the CFA ranged from 0.2 to 0.76, indicating no multicollinearity.<sup>29</sup>  
20 Approximate fit to the four-factor model was not achieved (Table 5), therefore we  
21 conducted an EFA.

22 Three factors had eigenvalues > 1, six factors > 0.7 and the scree plot was slightly  
23 ambiguous, showing inflexions that would justify retaining two or three factors (Appendix  
24 S2). The parallel analysis diverged from these results, suggesting a 26-factor model (Table  
25 S7). We consequently ran six EFAs setting the number of factors to retain manually at 5, 2,  
26 3, 6, 4, and 1.  
27

## 1 **PRIDD V0.2**

2 The 6-factor model was the 'cleanest' (Table S8) and item clustering suggested the following  
3 underlying concepts:

- 4 • Factor 1: Negative Affect
- 5 • Factor 2: Physical Impact
- 6 • Factor 3: Appearance-Related Concerns
- 7 • Factor 4: Life Responsibilities Impact
- 8 • Factor 5: Interpersonal Relationships
- 9 • Factor 6: Identity

10 All factors were internally consistent (Appendix S3), however, Negative Affect demonstrated  
11 item redundancy ( $\alpha = 0.91$ ). The item 'I have struggled to concentrate' had the highest ' $\alpha$  if  
12 item deleted' value and was therefore removed, leaving 25 items (PRIDD V0.2).

13 All six factors showed at least some misfit to the Rasch model (Table S9). Five factors  
14 showed local dependency (Appendix S4). Correction involved removing three items and  
15 grouping six other items into three testlets. This produced three factors with less than three  
16 items, the minimum recommended number of items in a scale.<sup>18,30</sup> Given the conceptual  
17 overlap of the remaining items, Appearance-Related Concerns was combined with Negative  
18 Affect to create Psychological Impact, and Interpersonal Relationships and Identity to make  
19 Social Impact. This resulted in a 22-item, four-factor model (PRIDD V0.3).

## 20 **PRIDD V0.3**

21 This four-factor model achieved approximate fit and met the COSMIN criteria for structural  
22 validity (Table 5). All factors were internally consistent (Table S10) but showed some misfit  
23 to the Rasch model (Table S11). This improved upon removal of two items: 'I have been  
24 hiding, covering or concealing my condition' (Psychological Impact) and 'I have been  
25 excluded, stigmatised or discriminated against by others' (Social Impact)

## 26 **PRIDD V0.4**

27 In this 20-item version, all factors were strictly unidimensional and had no evidence of DIF,  
28 except for Life Responsibilities Impact, though this cancelled out at test level (Appendix S5).  
29 That is, the effects from the item exhibiting DIF for those with an inflammatory condition

1 was cancelled out by the item exhibiting DIF for those with a non-inflammatory condition.  
2 The Person-Item Threshold Distribution graphs indicated that the addition of an item  
3 capturing more 'severe' impact to each factor would improve targeting (Figure S3). We  
4 added four items based on patient prioritisation of items during the previous Delphi study  
5 (Table S12).<sup>13</sup> Stigma ('I have been excluded, stigmatised or discriminated against by others')  
6 emerged as an important impact during the content validity phase<sup>15</sup> but was not captured  
7 by any of the included Social Impact items. While this item was not required for this  
8 subscale to fit the Rasch model, we decided to retain this item for further testing alongside  
9 the additional item above. This resulted in a 24-item, four-factor version (PRIDD V0.5).

#### 10 **PRIDD V0.5**

11 The first three additional items plus the stigma item showed disordered thresholds.  
12 Combining adject response categories improved fit to the model (Figure 1). All factors  
13 demonstrated at least some misfit to the model (Table 4), with some also showing breaches  
14 of unidimensionality, local dependency (Appendix S6) and DIF (Appendix S7).

#### 15 **PRIDD V1**

16 Removal of nine items across the four factors (Table S13) resulted in a 16-item PRIDD  
17 (PRIDD V1) with each dimension (Table 6) and item (Table 7) showing fit to the Rasch model,  
18 strict unidimensionality, no local dependence (Appendix S8), no DIF at the test level  
19 (Appendix S9), and was well-targeted (Figure 2).

20 The R (0.84) and A values (0.95) demonstrated high average pairwise correlation and very  
21 high levels of common variance between the four subscales, indicating that summing the  
22 four subscales to obtain an 'overall impact' total score was valid.

#### 23 **PRIDD scoring**

24 PRIDD total (0 - 63) and subscale scores are obtained in a two-step process by summing item  
25 scores and transforming these raw, ordinal level scores to interval level data using a  
26 conversion table (full instructions in Appendix S10).

27

#### 28 **Discussion**

1 This field test study represents the fourth of five steps in PRIDD's development and  
2 validation. It examined PRIDD's factor structure and established the definitive selection of  
3 items for each subscale. The findings and resultant adjustments produced the final 16-item  
4 PRIDD within four domains.

5 This study further supported PRIDD's content validity, feasibility and refined the conceptual  
6 framework of the impact of dermatological conditions.<sup>12,14</sup> While we found support for each  
7 of the original five domains of impact; the data indicated a four-factor model (Figure 3)  
8 consisting of Physical Impact, Life Responsibilities Impact (combining the previous daily life  
9 and responsibilities and financial impacts domains), Psychological Impact and Social Impact  
10 subscales. This validated conceptual framework provides clinicians and researchers with a  
11 valuable, theoretically coherent framework for understanding and measuring the impact of  
12 dermatological conditions. The multidimensionality demonstrates that holistic,  
13 multidisciplinary approaches are fundamental to high-quality, personalised dermatological  
14 care. PRIDD total and subscales scores can indicate targets for interventions and guide  
15 shared decision-making and referral to appropriate specialists such as psychologists and  
16 occupational therapists.

17 Structural validity is an important psychometric property and unidimensionality, the  
18 assumption that a scale (or subscale) measures a single construct, is fundamental to this.  
19 There is generally poor or mixed evidence for unidimensionality across many of the  
20 commonly used dermatology-specific PROMs. This is often because unidimensionality has  
21 been assumed but not tested or because of a reliance on CTT methods over IRT methods.  
22 For example, the three subscales of the Skindex-29 – emotions, symptoms, and functioning -  
23 were established using Cronbach's alpha and correlations.<sup>36</sup> However, a Rasch analysis  
24 found evidence of unidimensionality for only two subscales: symptoms and combined  
25 emotions and functioning.<sup>37</sup> It is also often erroneously assumed that PROM subscales can  
26 automatically be summed to obtain a total score. This study provides empirical evidence  
27 that PRIDD and all four subscales are unidimensional and can be validly combined into a  
28 total score. This means that PRIDD can not only provide a single score of overall impact, but  
29 the subscales can be used individually to distinguish among the domains of impact, making  
30 it a powerful and versatile tool.

1 Existing dermatology-specific PROMs were developed with a small number of patients in  
2 one country and subsequently used globally, with limited revalidation. As PRIDD is intended  
3 for use with adults with a dermatological condition worldwide, we recruited geographically  
4 diverse samples throughout all stages of PRIDD's development to enhance transferability.  
5 The final version of PRIDD, tested with this heterogeneous study sample, showed no DIF,  
6 indicating that it is well-worded and appropriate for use with the global dermatology patient  
7 population. These results attest to the value of developing and validating PROMs with an  
8 inclusive, patient-centered approach and following best practices, including a rigorous pilot  
9 test, use of both CTT and modern psychometric methods, and combining participatory and  
10 statistical methods of item reduction.

11 Researchers, clinicians, and regulatory agencies should choose measurement instruments  
12 based on their quality. The next and final step in PRIDD's development will be a study to test  
13 the remaining measurement properties, interpretability information (e.g. Minimally  
14 Important Change)<sup>38</sup> and comparison with other well used measures. Subsequently, PRIDD  
15 will undergo cultural translation, linguistic validation, and be used to collect global data on  
16 the life impact of dermatological conditions. It will also be beneficial to revalidate PRIDD's  
17 measurement properties in a sample of patients not involved in the original development  
18 and validation. The

### 19 **Strengths and limitations**

20 This study met the highest standards for tests of structural validity (Table S14) and internal  
21 consistency outlined by COSMIN (Table S15).<sup>39</sup> We recruited a diverse sample enabling us to  
22 test PRIDD's performance across a range of subgroups. However, as participants were  
23 primarily recruited through patient organisations and the sample was predominantly White  
24 and well-educated, these results may not be representative of the dermatology patient  
25 population. As we used the same recruitment methods for both surveys, it is possible that  
26 there was overlap between samples, but we were unable to verify this. We were also not  
27 able to check that all participants were sufficiently proficient in English.

28 Using a combination of classical and modern psychometric methods enabled us to select the  
29 best statistical methods for assessing structural validity and internal consistency. Data  
30 triangulation from the multiple methods used – CFA, EFA, parallel and Rasch analysis –  
31 provide strong support for the conceptual framework. The sample was relatively large for

1 factor and Rasch analyses, increasing the generalisability of the conclusions.<sup>35</sup> Existing  
2 dermatology-specific PROMs use ordinal, Likert-type responses meaning that intervals  
3 between successive points on the scales are not intrinsically equal.<sup>40</sup> This leads to challenges  
4 in comparing intervention efficacy across patients with PROM scores on different portions  
5 of the scale.<sup>41</sup> Using Rasch analysis allowed us to transform PRIDD's ordinal responses into  
6 interval level scores. This optimises the level of quantitative information that can be  
7 obtained, including the calculation of mean and change scores without the restrictions of  
8 nonparametric, representational measurement,<sup>37</sup> and enables valid comparison of scores  
9 across the scale.<sup>34</sup> We therefore recommend using the transformed rather than the raw  
10 scores, though the latter may be more feasible in routine practice.  
11 While we previously employed participatory methods to prioritise items for inclusion in  
12 PRIDD, this study used purely statistical techniques of item reduction, which may reduce  
13 item content coverage and consequently content validity. We recommend that PROM  
14 developers consider involving patients during final item selection to ensure a good balance  
15 between face validity and psychometric performance and ensure the final PROM is  
16 acceptable to the target population.

## 18 **Acknowledgements**

19 We would like to thank GlobalSkin for their efforts in conceiving of the Global Research on  
20 the Impact of Dermatological Diseases (GRIDD) project, project management, and recruiting  
21 participants for this study. We are thankful for the generous involvement of participants for  
22 sharing their expertise and experiences with us and acknowledge the support of  
23 GlobalSkin's patient organisation members. We are grateful to Mike Horton (University of  
24 Leeds, UK) for his invaluable expert support and guidance on Rasch analysis. We also wish to  
25 acknowledge the input of those serving on the GRIDD project's Scientific Advisory Board:  
26 Ramesha Bhat (Father Muller Medical College, India), Arnon D. Cohen (Clalit Health Services,  
27 Israel), Ncoza Dlova (Nelson R Mandela School of Medicine, South Africa), Toshiya Ebata  
28 (The Jikei University School of Medicine, Japan), Cristina Echeverría (ECHO Psoriasis,  
29 Argentina), Alice Gottlieb (Icahn School of Medicine at Mt. Sinai, US), Andrew Finlay (Cardiff  
30 University, UK), Luigi Naldi (Ospedale San Bortolo di Vincenza, Italy), Lone Skov (University

1 of Copenhagen, Denmark), and Marc Yale (International Pemphigus Pemphigoid  
2 Foundation, US).

ACCEPTED MANUSCRIPT

1 **Table 3: Steps in the iterative Rasch analysis**

1	Threshold ordering	<p>Rating scales function optimally when thresholds are ordered. Thresholds correspond with the threshold points between two different scores on the rating scale, in this case 'never' to 'always'. At the threshold point, it is equally likely to obtain either score (i.e. the probability of scoring 2 or 3 on the item is 50/50). This is demonstrated by category probability curves where each curve shows a distinct peak which illustrates the position along the continuum where the categories are most likely to be selected.<sup>46,47</sup> This indicates that respondents are able to discriminate between response options.<sup>47,48</sup></p> <p>Disordered thresholds indicate that an item is not working properly as the response categories are not progressing in a logical order. In this case, even when the probability of selecting a particular response option is at its highest, it is still more likely that another option will be selected.</p> <p>We examined threshold ordering visually using the threshold map. The category probability curves of disordered thresholds were visually inspected to determine whether the item response options were functioning optimally and whether rescoring was indicated.</p>
2	Tests of fit	<p>Model fit was acceptable if the item-trait interaction, reported as chi-square, was non-significant (<math>p &gt; .05</math>) and the item and person residuals had <math>\bar{x} \approx 0</math> and <math>SD \approx 1</math>. Individual items and persons were regarded as misfitting if their residuals fell outside of the range of <math>\pm 2.5</math>. Individual items were also tested by chi-square and F-tests.</p>
3	Unidimensionality	<p>Strict unidimensionality was confirmed with a series of t-tests reporting significantly different person estimates in <math>&lt; 5\%</math> of cases (or the lower bound of the 95% CI <math>&lt; 5\%</math>).</p>
4	Local independence	<p>Local dependency among the items was assessed via the residual correlations using a cut-point of the average plus 0.2.<sup>49</sup></p>
5	Differential item functioning (DIF)	<p>DIF occurs when members from different groups who have the same level of the latent trait (i.e. impact) have a different probability of giving a certain response to an item. DIF was tested by:</p> <ul style="list-style-type: none"> <li>• gender (male or female)</li> <li>• age group (four equal groups - Survey 1: 18-36, 37-55, 56-74, 75-90; Survey 2: 18-37, 38-57, 58-77, 78+)</li> <li>• inflammatory type (inflammatory and non-inflammatory). Inflammatory type was chosen over discrete diseases as DIF analysis can handle no more than four categories. For categorisation of diseases see Table S2.</li> <li>• highest qualification</li> <li>• English as a first language (yes or no)</li> </ul> <p>A statistically significant Bonferroni-adjusted <math>p</math> value indicated DIF.</p>
6	Targeting	<p>We visually inspected the Person-Item Threshold Distribution graphs and reported the <math>\bar{x}</math> person location value. Mean person locations within <math>+0.5</math> logits of the mean item location (i.e. 0 logits) suggested acceptable targeting.<sup>50</sup></p>

# THE OPPORTUNITY FOR COMPLETE, FAST AND LASTING SKIN CLEARANCE<sup>1,2</sup>

68.2% achieved PASI 100 at Week 16<sup>†1</sup>

75.9% of patients achieved PASI 75 at Week 4<sup>†1</sup>

82% of week 16 PASI 100 responders maintained this response up to 3 years<sup>2</sup>

BIMZELX was well tolerated, the most frequently reported adverse reactions were: upper respiratory tract infections (14.5%, 14.6%, in plaque psoriasis (Pso), and psoriatic arthritis (PsA) respectively) and oral candidiasis (7.3%, 2.3% in Pso, and PsA respectively). Other common reported adverse reactions include Tinea infections, Ear infections, Herpes simplex infections, Oropharyngeal candidiasis, Gastroenteritis, Folliculitis, Headache, Rash, Dermatitis, Eczema, Acne, Injection site reactions, and Fatigue.

Please refer to the SmPC for further information.<sup>1</sup>

**Footnotes:** <sup>†</sup>co-primary endpoints PASI 90 and IGA 0/1 at Week 16

Pso - Plaque Psoriasis; PsA - Psoriatic Arthritis

**BIMZELX<sup>®</sup> (Bimekizumab)** is indicated for the treatment of moderate to severe plaque psoriasis in adults who are candidates for systemic therapy. Bimzelx, alone or in combination with methotrexate, is indicated for the treatment of active psoriatic arthritis in adults who have had an inadequate response or who have been intolerant to one or more disease-modifying antirheumatic drugs (DMARDs). Please refer to the SmPC for further information.<sup>1</sup>

## PRESCRIBING INFORMATION FOR HCP'S IN GREAT BRITAIN

**BIMZELX<sup>®</sup> (Bimekizumab)** is indicated for the treatment of moderate to severe plaque psoriasis in adults who are candidates for systemic therapy, and for active psoriatic arthritis in adults who have had an inadequate response or who have been intolerant to one or more disease-modifying antirheumatic drugs (DMARDs), alone or in combination with methotrexate.<sup>1</sup> (Please consult the Summary of Product Characteristics (SmPC) before prescribing).

**Active Ingredient:** Bimekizumab – solution for injection in pre-filled syringe or pre-filled pen: 160 mg of bimekizumab in 1 mL of solution (160mg/mL). **Indications:** Moderate to severe plaque psoriasis in adults who are candidates for systemic therapy. Alone or in combination with methotrexate, for active psoriatic arthritis in adults who have had an inadequate response or intolerant to one or more disease-modifying antirheumatic drugs (DMARDs). Adults with active non-radiographic axial spondyloarthritis with objective signs of inflammation as indicated by elevated C-reactive protein (CRP) and/or magnetic resonance imaging (MRI) who have responded inadequately or are intolerant to non-steroidal anti-inflammatory drugs (NSAIDs). Adults with active ankylosing spondylitis who have responded inadequately or are intolerant to conventional therapy.

**Dosage and Administration:** Should be initiated and supervised by a physician experienced in the diagnosis and treatment of conditions for which Bimzelx is indicated. **Recommended dose:** Plaque Psoriasis: 320 mg (given as two subcutaneous injections of 160 mg each) at week 0, 4, 8, 12, 16 and every 8 weeks thereafter. Psoriatic arthritis: 160 mg (given as 1 subcutaneous injection of 160 mg) every 4 weeks. For psoriatic arthritis patients with coexistent moderate to severe plaque psoriasis, the recommended dose is the same as for plaque psoriasis. After 16 weeks, regular assessment of efficacy is recommended and if a sufficient clinical response in joints cannot be maintained, a switch to 160 mg every 4 weeks can be considered. Axial spondyloarthritis (nr-axSpA and AS): 160 mg (given as 1 subcutaneous injection) every 4 weeks. For patients with plaque psoriasis (including psoriatic arthritis with coexistent moderate to severe psoriasis) and a body weight  $\geq$  120 kg who did not achieve complete skin clearance at week 16, 320 mg every 4 weeks after week 16 may further improve treatment response. Consider discontinuing if no improvement by 16 weeks of treatment. Renal or hepatic impairment: No dose adjustment needed. Elderly:

No dose adjustment needed. Administer by subcutaneous injection to thigh, abdomen or upper arm. Rotate injection sites and do not inject into psoriatic plaques or skin that is tender, bruised, erythematous or indurated. Do not shake pre-filled syringe or pre-filled pen. Patients may be trained to self-inject. **Contraindications:** Hypersensitivity to bimekizumab or any excipient; Clinically important active infections (e.g. active tuberculosis). **Warnings and Precautions:** Record name and batch number of administered product. **Infection:** Bimekizumab may increase the risk of infections e.g. upper respiratory tract infections, oral candidiasis. Caution when considering use in patients with a chronic infection or a history of recurrent infection. Must not be initiated if any clinically important active infection until infection resolves or is adequately treated. Advise patients to seek medical advice if signs or symptoms suggestive of an infection occur. If a patient develops an infection, the patient should be carefully monitored. If the infection becomes serious or is not responding to standard therapy do not administer bimekizumab until infection resolves. **TB:** Evaluate for TB infection prior to initiating bimekizumab – do not give if active TB. While on bimekizumab, monitor for signs and symptoms of active TB. Consider anti-TB therapy prior to bimekizumab initiation if past history of latent or active TB in whom adequate treatment course cannot be confirmed. **Inflammatory bowel disease:** Bimekizumab is not recommended in patients with inflammatory bowel disease. Cases of new or exacerbations of inflammatory bowel disease have been reported. If inflammatory bowel disease signs/symptoms develop or patient experiences exacerbation of pre-existing inflammatory bowel disease, discontinue bimekizumab and initiate medical management. **Hypersensitivity:** Serious hypersensitivity reactions including anaphylactic reactions have been observed with IL-17 inhibitors. If a serious hypersensitivity reaction occurs, discontinue immediately and treat. **Vaccinations:** Complete all age appropriate immunisations prior to bimekizumab initiation. Do not give live vaccines to bimekizumab patients. Patients may receive inactivated or non-live vaccinations. **Interactions:** A clinically relevant effect on CYP450 substrates with a narrow therapeutic index in which the dose is individually adjusted e.g. warfarin, cannot be excluded. Therapeutic monitoring should be considered. **Fertility, pregnancy and lactation:** Women of child-bearing potential should use an effective method of contraception during treatment and for at

least 17 weeks after treatment. Avoid use of bimekizumab during pregnancy. It is unknown whether bimekizumab is excreted in human milk, hence a risk to the newborn/infant cannot be excluded. A decision must be made whether to discontinue breast-feeding or to discontinue/abstain from Bimzelx therapy. No data available on human fertility. **Driving and use of machines:** No or negligible influence on ability to drive and use machines. **Adverse Effects:** Refer to SmPC for full information. Very Common ( $\geq$  1/10): upper respiratory tract infection; Common ( $\geq$  1/100 to  $<$  1/10): oral candidiasis, tinea infections, ear infections, herpes simplex infections, oropharyngeal candidiasis, gastroenteritis, folliculitis; headache, rash, dermatitis and eczema, acne, injection site reactions, fatigue; Uncommon ( $\geq$  1/1,000 to  $<$  1/100): mucosal and cutaneous candidiasis (including oesophageal candidiasis), conjunctivitis, neutropenia, inflammatory bowel disease. Storage precautions: Store in a refrigerator (2°C – 8°C), do not freeze. Keep in outer carton to protect from light. Bimzelx can be kept at up to 25°C for a single period of maximum 25 days with protection from light. Product should be discarded after this period or by the expiry date, whichever occurs first.
