#### Abstract

This thesis is composed of two central themes of research; Chapters 2-6 describe efforts to understand and increase the activity of iminium ion catalysts. Chapters 7-9 are free-standing investigations exploring concepts and observations that were encountered through the course of the research.

Chapter 1 briefly introduces iminium ion catalysis before discussing the experimental and theoretical techniques that are routinely applied to investigate reaction mechanism. The discussion of techniques is divided into three sections; structural, kinetic and theoretical methods. This is followed by a passage that highlights the reported techniques that have been applied to understand mechanisms of iminium ion catalysed processes.

Chapter 2 highlights the work previously conducted within the group developing catalysts for the iminium ion catalysed Diels-Alder reaction and describes a SAR study designed to understand the relationship between the $\alpha$-effect and $\beta$-EWG components of catalysts to aid future catalyst design. The study found that the components work independently. Chapter 3 describes a further SAR study conducted to provide evidence for the role of the $\beta$-EWG in increasing catalyst activity. The important conclusions drawn were that $\beta$-EWG was not acting as a proton shuttle as previously hypothesised and that EWG's that do not contain a carbonyl group could be exploited to increase the activity of a catalyst.

Chapter 4 describes investigations into mechanistic aspects of the catalytic cycle for the iminium ion catalysed Diels-Alder reaction. The isolation of key iminium ion intermediate allowed for structural studies and kinetic investigations of the individual steps of the catalytic cycle. The Diels-Alder cycloaddition was found to be the RDS and the physical reasons for this were understood. The hypothesis was formed that a lowering in the LUMO energy of the dienophile by including a strong $\beta$-EWG into the catalyst would accelerate the overall catalytic cycle.

Chapter 5 describes the application of our findings to the design and synthesis of more active catalysts based around the scaffold of MacMillans imidazolidinone catalyst. The inclusion of an additional $\beta$-EWG within the catalyst scaffold provided unprecedented levels of activity supporting our hypothesis. The development and evaluation of a predictive theoretical tool for catalytic activity is also discussed.

Chapter 6 shows the preliminary development of piperazinones as catalyst for the iminium ion catalysed Diels-Alder reaction of aldehydes and ketones. Chapter 7 describes our efforts to develop a chiral dynamic resolution procedure for the iminium ion catalysed Michael addition reaction of nitroalkanes to $\alpha, \beta$-unsaturated ketones.

Chapter 8 reports the development of a one-pot monocarboxymethylation procedure for primary amines and diamines using glyoxylic acid under mild conditions. Chapter 9 describes the first aminocatalytic method for the preparation of non-natural and natural bis-indolyl alkanes.

## Acknowledgements

I would like to thank Dr Nick Tomkinson for all his support and wisdom throughout my studies at Cardiff University. Nick has provided excellent supervision and furthered my education both scientifically and personally for which I am extremely grateful. I also gratefully thank Dr Jamie Platts for his supervision and discussions on theoretical aspects of my work.

Thanks is extended to all the technical staff at Cardiff University particularly Dr Rob Jenkins for his extensive expertise and patience.

I would also like to thank my fellow group members Dr. Ian Jones, Dr. Garth Evans, Dr. Antonio Ruda, Dr. John Brazier, Michael Boomhoff, Eva Vogt and Gemma Talbot with who I have collaborated and also Dr. Teyrnon Jones, Dr. Jacky Yau, Dr. Eve Bridgeman, Dr. Rob Strevens, Dr. Achim Porzelle, Dr. Niall Killeen, Huw Davies, Kerri Jones, Paul Taylor, Deb Knowles, Kevin Jones and Oliver Stradling-John each of which has provided a forum for scientific and non-scientific discussions. Thanks goes to Eleanor Merritt and Dr. Matt Dix for instruction for the microwave experiments and also to other the members of Dr. Mark Bagley's Group.

I would like to thank my partner Bethan for her enduring unconditional loving support and understanding along with family members James, Sara, Martin, Caitlin, Tom, Megan, Phil amongst others. A number of other people have touched and enriched my life in a variety of ways and although you are not explicitly mentioned I ensure that I extend my sincere thanks for all you have done.

Finally, it is with extreme gratitude that I thank my Father Richard and late Mother Diana who throughout my youth invested their time and effort in encouraging me to pursue my interest in science and the natural world. It is they that I must thank for everything that I have achieved. This debt cannot be repaid and hence they have shown me true generosity.

# Chapter 1: Introduction: Techniques Available for the Elucidation of Reaction Mechanism and their Application to Iminium ion Catalysis 

### 1.1 Introduction

### 1.1.1 Asymmetric Catalysis within Synthetic Chemistry

The concept of asymmetric catalysis is arguably the most appealing in synthetic chemistry as it allows for the preparation of valuable chiral products with substoichiometric quantities of catalysts. Asymmetric catalysis has distinct advantages over resolution and chiral pool methods by minimising waste and providing a broad substrate scope. The area receives significant attention in a wide range of chemical research disciplines and continues to grow as a concept and a science.

### 1.1.2 Organocatalysis

Organocatalysis can be defined as 'the acceleration of chemical reactions with a substoichiometric amount of organic compound which does not contain a metal atom'.' Asymmetric organocatalysis was first practised in the 1970 's ${ }^{2}$ using proline but it was only at the start of this decade that the potential of the field was realised and exploited. The growth and expansion of the area is illustrated by analysis of the annual publications within the discipline over the last ten years (Figure 1.1).

(Figure 1.1) Number of publications vs year based on a SciFinder search using 'Organocatalysis' as the key word.

### 1.1.3 Organocatalysis within Asymmetric Catalysis

Of the efficient catalytic asymmetric reactions known, the majority involves an organometallic species. These metal catalysed reactions are widely used within chemical research but do not figure so prominently in industrial processes due to the expenses of scale. Therefore, development of less sensitive and less toxic methods is of interest in all aspects of synthetic chemistry. The future for development of efficient, robust, non-toxic and environmentally benign systems is far brighter for the field of organocatalysis.

Organocatalysis is an attractive alternative to metal catalysed processes and frequently provides superior levels of enantioenrichment. The field of organocatalysis has produced a remarkable number of efficient systems in its short history. ${ }^{1}$ Organocatalysis is still very much in its infancy and therefore should not currently be viewed as an alternative to metal based catalysis but as a complimentary tool to be used in conjunction with existing methods to realise synthetic targets.

### 1.1.4 Classification of Organocatalysts

Organocatalytic processes can be classified according to the mode of action of the catalyst; ${ }^{3}$

- Lewis acid catalysis
- Brønsted acid catalysis
- Lewis base catalysis
- Brønsted base catalysis

Within the literature, examples of each mode have been described. However, the majority of reported transformations are in the Lewis base category and involve the formation of iminium ions or enamines as the key catalytic intermediates.

### 1.1.5 Enamine Catalysis

Enamine catalysis represents the most successful branch of organocatalysis to date. Conceptually, enamine catalysis can be thought of as an alternative method for the generation of enolates that has numerous practical advantages over traditional methods. Enamine catalysis is a Lewis base method as the lone pair of the enamine raises the energy of the HOMO of the nucleophile increasing the associated nucleophilicity.

Enamine catalysis has been applied to many reactions that would normally involve the generation of an enolate. Catalysed reactions include the aldol, ${ }^{4}$ Robinson annulation, ${ }^{5}$ Mannich, ${ }^{6} \alpha$-amination, ${ }^{7} \alpha$-aminooxylation, ${ }^{8}$ conjugate addition, ${ }^{9}[4+2]$ cycloaddition, ${ }^{10}$ $[2+2]$ cycloaddition ${ }^{11}$ and the Mortia-Baylis-Hillman reaction, ${ }^{12}$ among others. The general enamine catalytic cycle for proline is shown below (scheme 1.1).

(Scheme 1.1)

Condensation of the amine catalyst (1) and a carbonyl (2) gives an iminium ion which is rapidly converted to the nucleophilic enamine species 3 . The enamine is sufficiently reactive to attack electrophile 4 which generates an iminium ion 5 . Subsequent hydrolysis releases the reaction product $\mathbf{6}$ along with the amine catalyst $\mathbf{1}$ to continue the catalytic cycle.

### 1.1.6 Iminium ion catalysis

Conceptually, iminium ions can be thought of as being analogous to Lewis acid activated $\alpha, \beta$-unsaturated carbonyl compounds and they posses similar $\pi$-electronics (Scheme 1.2). Iminium ions increase activity by accepting electron density from the $\mathrm{C}=\mathrm{C}$ of the parent $\alpha, \beta$-unsaturated carbonyl compound and thus lower the energy of the LUMO (the $\pi^{*}$ of the iminium ion derived from the parent carbonyl compound) which decreases the energy difference for interaction with the HOMO of the reaction partner resulting in a lower energy transition state and hence rate acceleration.

(Scheme 1.2)

The use of iminium ion technology has distinct practical advantages over the majority of Lewis acid catalysed reactions. The iminium ion catalysed reactions are inherently tolerant to air and moisture and are often conducted at ambient temperature. The area of iminium ion catalysis has been extensively reviewed. ${ }^{13}$ To date this methodology has been used in a number of asymmetric organic transformations including Diels-Alder ${ }^{14}$ and [3+2] dipolar cycloadditions, ${ }^{15}$ Michael ${ }^{16}$ and conjugate ${ }^{17}$ additions, conjugate reductions, ${ }^{18}$ ene reactions, ${ }^{19}$ cyclopropanations, ${ }^{20}$ aziridinations ${ }^{21}$ and epoxidations. ${ }^{22}$

Structurally, the favoured catalysts for iminium ion accelerated processes are based around pyrrolidine (e.g. 11) or imidazolidinone scaffolds (e.g. 7-10), using the high nucleophilicity of the nitrogen lone pair generated by ring strain. The use of a co-acid is necessary to accelerate formation and hydrolysis of the reactive iminium ions, allowing for greater efficiency in the overall process.

### 1.2 Methods of Determining Reaction Mechanism

### 1.2.1 Mechanism

Reactions are often written as simple transformations involving the conversion of one molecule to another. In actual fact, discreet intermediates are often involved. The study of mechanism is to understand the structural, thermodynamic and chemical relationships between each of the individual species that are formed in a reaction sequence.

Although the methods available to study mechanism have been categorised and discussed individually in this thesis, a single method provides insufficient evidence to confirm a proposed mechanism (although a single valid experiment is sufficient to discount a proposed mechanism). Therefore, numerous methods are often employed to provide sufficient evidence to support a mechanistic proposal.

### 1.2.2 The Philosophical Background to Physical Organic Chemistry ${ }^{24}$

Before discussion of the toolkit available to elucidate mechanism it is worth highlighting the philosophical constraints that an experimentalist must operate under. Detailed discussion can be found in historic and philosophical texts. ${ }^{23}$ The principle concept is that it is not possible to prove the mechanism of a reaction. It is, however, possible to disprove a mechanism by providing evidence to the contrary. Therefore, the acceptance of mechanism is based around strong supporting evidence in the absence of conflicting evidence.

Chapter 1 TJ K Gibbs- PhD Thesis 2008

A mechanism is to all extents and purposes a product of the human mind and therefore to ensure that a proposed pathway is reasonable there are some minimum requirements that a proposed mechanism should posses before consideration. ${ }^{24}$ The proposed mechanism should be:-

- Consistent with all of the available experimental data and should not be in direct conflict with any data (provided there is not strong independent evidence which devalues the contradicting evidence). Neutrality can be accepted on certain issues.
- Testable by experimental means that would provide evidence to the contrary if not successful.
- Where possible, free of ad hoc modifications to explain inconsistencies with experimental observations.

In the event that numerous mechanistic proposals are consistent with minimum requirements, and equally consistent with available experimental data, then favour is given to the simplest.

### 1.2.3 The Toolkit

Currently, chemists have a plethora of techniques at their disposal to gain insight into the mechanics of a reaction. These methods can be categorised into three main groups; structural, thermodynamic and theoretical. The following passage will provide a brief overview of the techniques that are often employed to provide evidence for mechanistic pathways.

### 1.2.4 Structural Methods

Structural studies are the simplest and often the most definitive method for providing evidence for a mechanistic pathway. These studies take the form of isolating and characterising reaction products and/or intermediates using physical methods such as spectroscopy and crystallography. The structure of reaction products often contain information which can be used to infer the reactants and intermediates that preceded them.

There are many techniques available that relate spectroscopic properties to physical structure. Such techniques include, infra-red spectroscopy (IR), ultra-violet spectroscopy (UV), fluorescence spectroscopy, ESR spectroscopy, mass spectrometry, NMR spectroscopy, atomic spectroscopy and X-ray crystallography.

### 1.2.4.1 Product Studies

The detection of chirality within a product can provide valuable information regarding the symmetry of the preceding intermediates or transition states, ${ }^{25}$ however, the absolute configuration of the products must first be determined. This is frequently achieved by sophisticated spectroscopic methods or X-ray crystallography. A classic application of chirality study is the nucleophilic substitution reactions on aliphatic carbons achieved in the $19^{\text {th }}$ century. ${ }^{26}$ Modern chirality studies can take a number of forms from racemisation or exchange studies to sophisticated mechanistic tools such as the Tolbert analysis ${ }^{27}$ and concepts such as the Skell hypothesis ${ }^{28}$ which have been used to investigate the mechanisms of many reactions. ${ }^{29}$

The use of isotopic labelling has also emerged as a powerful tool in mechanistic determination. ${ }^{30}$ Isotopes possess the same chemical properties but differ in their physical properties, for example, molecular weight and NMR activity. This provides a convenient tool to monitor the final positions of labelled atoms within reaction products. A classic example of isotopic labelling is the hydrolysis of esters. ${ }^{31}$ The use of ${ }^{18} \mathrm{O}$ labelled water can provide evidence as to whether acyl (13) or alkyl (14) bond cleavage occured in ester
hydrolysis reaction (Scheme 1.3). Labelling experiments however, can be applied to more complex systems, for example, the ozonolysis of olefins. ${ }^{32}$

(Scheme 1.3)

Mechanistic information can also be provided by variation of the reaction conditions. Common variables include reaction time and temperature. This method, however, must be validated as altering the conditions may lead to an alteration of the mechanism. A reduction in reaction temperature can often allow for the detection and isolation of intermediates. Additionally, lengthening reaction times of reversible reactions encourages the formation of greater quantities of the thermodynamic product.

### 1.2 4. 2 Intermediate Studies

Product studies can be of limited use as it is possible that many intermediates could lead to a given product. Therefore, it is desirable to isolate or directly detect intermediate species within a reaction sequence. Intermediates can often be detected with routine analysis such as GC-MS or NMR techniques under normal chemical conditions. However, this is not always possible and therefore numerous methods have been developed to detect and characterise intermediate species.

Low temperature techniques are often employed to increase the lifetime of transient species. An example of such a technique is matrix isolation infra-red spectroscopy where intermediates are trapped using a solid argon matrix. ${ }^{33}$ Intermediate compounds such as benzyne 16 and cylclobutadiene 15 have been characterised by this method (Figure 1.3).

15

16
(Figure 1.3)

Chemical trapping of intermediates is also possible where a reagent is introduced that is designed to react with an intermediate to yield a distinct product. A classic example is that of TEMPO 17, which is routinely used to selectively trap carbon centred radicals 18 (Scheme 1.5). ${ }^{34}$ Conjugated dienes have also been used successfully to trap benzyne intermediates $16{ }^{35}$ which have only been physically detected through matrix isolation. ${ }^{36}$

(Scheme 1.5)

Many sophisticated spectroscopic techniques have also emerged for direct detection of intermediates. NMR, ESR, mass spectrometry and laser techniques can all be employed. NMR has been used to detect and characterise carbonium ions in superacid media ${ }^{37}$ and techniques developed such as spin-saturation transfer ${ }^{38}$ while ESR has proved a reliable method for the detection of radical intermediates. ${ }^{39}$ The unique properties of laser radiation have lead to the development of spectroscopy on a picosecond timescale for the detection of short lived intermediates. ${ }^{40}$
$\qquad$ T J K Gibbs-PhD Thesis 2008

### 1.2.5 Kinetic Methods

Once the species that are involved in a mechanistic pathway have been identified it is often desirable to conduct studies to understand the relationships of the individual components. This provides information that will subsequently lead to a fundamental understanding of the transformation.

### 1.2.5.1 Rates of Reaction

Measurement of the rate of a chemical transformation is of fundamental importance. The reaction order for a proposed mechanism can be predicted. Experimental determination of the order of reaction provides strong evidence to support or discount a mechanism. It is noteworthy however, that many proposed mechanisms may be predicted to have the same reaction order. Rate measurements can be achieved by numerous methods that can quantitatively relate the concentration of a compound with time. UV and NMR are frequently used to monitor kinetics although numerous other techniques based on $\mathbb{R}$, fluorescence and calorimetry, amongst others, have been employed.

With the advent of modern instrumentation and techniques, the kinetics of reactions of the scale of $10^{-12} \mathrm{~s}$ can be determined. For reactions of the order $10^{-1}-10^{-3} \mathrm{~s}$ stopped flow methods are commonly applied. ${ }^{41}$ For reactions of the scale of $10^{-6}-10^{-12} \mathrm{~s}$ the use of pulses of electricity, sound or light (lasers are needed for the fastest reaction) are used to perturb systems from equilibrium and then the restoration of equilibrium is observed. ${ }^{41}$

The use of isotopes in kinetic measurements can yield valuable mechanistic data. Primary and secondary Kinetic Isotope Effects (KIE) have been exploited by mechanistic chemists. The physical origin for KIE is complex when constructed properly and is covered elegantly by Carpenter. ${ }^{42}$ Primary KIE's involve the cleavage of the isotope containing bond before or in the rate determining step whereas secondary KIE's involves cleavage of a bond $\alpha$ or $\beta$ to the isotopic atom. Primary KIE's can be successfully observed using a range of isotopic atoms while secondary KIE are of a much smaller magnitude and therefore only observable for X-H/D bonds.

The observation of a primary KIE provides evidence for participation of a bond breaking before or during the rate determining step of the reaction. The method has been applied successfully to rationalise the mechanism of many reactions.

The use of the Hammett equation is another method that allows the electronic nature of the transition state to be probed. Examination of the relationship of the electronic nature of substituents and the respective rate can provide evidence to support or eliminate mechanistic proposals. ${ }^{43}$

### 1.2.5.2 Activation Parameters

There are three equations that describe the temperature dependence of a reaction. The Arrhenius equation is the most simplistic model and allows for measurement of activation energy $\boldsymbol{E}_{a}$ along with a pre-exponential factor $\boldsymbol{A}$.

$$
k=A e^{-\frac{E a}{R T}}
$$

Transition state theory (Eyring equation) relates the rate constant $k$ to enthalpy of activation $\Delta H^{\ddagger}$ and the entropy of activation $\Delta S^{\ddagger}$.

$$
k=\frac{\mathbf{k} T}{h} e^{\frac{\Delta S^{\ddagger}}{R}} e^{-\frac{\Delta H^{\ddagger}}{R T}}
$$

Finally, collision theory is constructed from a detailed collision model $Z$ a steric factor $p$ and a Boltzmann energy term $-E^{*} / R T$. Collision theory is effective at predicting rate constants of simplistic reactions in the gas phase but is quite arbitrary for larger molecules and reactions in solution.

$$
k=p Z e^{-\frac{E^{*}}{R T}} \quad Z=d_{A B}^{2} \sqrt{\frac{8 \pi \mathrm{k} T}{m_{A} m_{B}}\left(m_{A}+m_{B}\right)}
$$

Using these equations it is possible to extract activation parameters provided that rate constants are measured at a range of temperatures. Methods such as Benson additives ${ }^{44}$
and computational chemistry can provide good estimates of activation parameters for proposed mechanisms and become powerful tools when combined with experimental data for supporting or eliminating mechanistic proposals.
$\qquad$

### 1.2.6 Theoretical Methods ${ }^{45}$

Chemists have always used theory to develop models to aid the understanding of chemical reactivity. In recent years there has been an explosion in computing technology and power. This affordable and accessible technology has allowed chemists to model more complex systems. Modern theoretical studies can contain tens of thousands of calculations which require computing ability that was not available until very recently.

Theoretical chemistry needs further development before it can be treated as a definitive tool for predicting and explaining reaction mechanism. However, theoretical chemistry is an extremely influential method when used in conjunction with physical experiment. Numerous theoretical models have emerged each with its merits and faults. An overview of the techniques frequently used is given below

### 1.2.6.1 Molecular Mechanics (MM)

Molecular Mechanics Force Field (MMFF) ${ }^{46}$ is the most simplistic theoretical model, requiring relatively small amounts of resources and providing cheap and rapid calculations, which are ideal for studying large systems such a proteins. Highly accurate MMFF models have been developed through careful parameterisation. ${ }^{47}$ MMFF is purely mechanical and therefore does not account for electron interactions and inadequately describes systems dominated by these effects. An example of a MMFF is MM2. The MM2 force field can be superficially described as: ${ }^{45}$

- Purely mechanical model (no electrons included)
- Can provide bond lengths accurate to 0.01 A
- Can provide bond angles within a few degrees
- Conformational energies to $1 \mathrm{kcal} \mathrm{mol}^{-1}$ with careful parameterisation
- Vibrational frequencies accurate to $20-30 \mathrm{~cm}^{-1}$

### 1.2.6.2 Self Consistent Field Theory (SCF)

The majority of theoretical techniques are based around SCF. The techniques involve the construction of a wavefunction in which a term describing the electron correlation is included. The varying expense and accuracy of these techniques is proportional to the manner in which electron interaction is considered. The simplest SCF treatments are semi-empirical methods ${ }^{48}$ that discard certain electron correlations in the wave function and subsequently introduce experimental or higher theoretical data. As with MMFF, semi-empirical methods rely on careful parameterisation for accuracy. A popular semiempirical method is the Austin Model 1 (AM1). Some interesting features of AM1 are highlighted below: ${ }^{45}$

- Direct calculation of valence electrons only
- Non-classical compounds considered to be less stable
- Faster calculations than higher SCF or DFT methods
- Sterically crowded and hyper coordinate compounds appear too unstable
- Rotational barriers often underestimated
- Four membered rings appear too stable
- Calculated activation barriers often too high
- For pericyclic reactions biradicaloid mechanisms favoured

In the Hartree-Fock (HF) ${ }^{49}$ model the influence that an electron feels is treated as the average field of all other electrons. This average treatment fails to account for specific electron repulsion and can lead to shorter bond lengths and higher total energies ( $\mathrm{E}_{\mathrm{HF}}$ ) than true energies, it also poorly describes highly delocalised systems. Common features of HF are: ${ }^{45}$

- Good accuracy for bond lengths and angles for standard organic molecules
- Conformational energies accurate to $1-2 \mathrm{kcal} \mathrm{mol}^{-1}$
- Vibrational frequencies systematically $10-12 \%$ too high for most covalent bonds
- Zero point vibrational energies inaccurate by $\sim 1-2 \mathrm{kcal} \mathrm{mol}^{-1}$
- Protonation/deprotonation energies in gas phase inaccurate by $\sim 10 \mathrm{kcal} \mathrm{mol}^{-1}$
$\qquad$ T J K Gibbs- PhD Thesis 2008
- Atomisation/homolytic bond-breaking reactions inaccurate by $25-40 \mathrm{kcal} \mathrm{mol}^{-1}$

In the instances when HF theory is inappropriate, e.g. when investigating aromaticity, polarisation or delocalisation, then use of higher level theories is needed that correlate electron-electron interactions. There are many different treatments of electron correlation from those just above HF to complex detailed theories. The high level SCF methods are considered to be the benchmark for theoretical calculations. The electron-correlation theories can be described as being: ${ }^{45}$

- Straightforward to interpret complete electronic description
- Highly accurate rivalling experiment for small organic molecules
- Very time consuming and therefore expensive
- Strongly basis set dependent
- Straightforward to improve systematically

### 1.2.6.4 Density Functional Theory DFT

DFT uses an electron density functional (e.g. B3LYP) ${ }^{50}$ to replace the many body electronic wavefunction used in methods based on HF. This treatment requires less computation time but is of similar accuracy, greatly reducing cost. In principle, DFT is an exact quantum mechanical method, providing that the true functional is known. However, a degree of arbitrariness is involved when choosing functional combinations and therefore validation of the results is often necessary. Another consequence of this is that systematic improvement is difficult. DFT methods often display the following features: ${ }^{45}$

- Straightforward interpretation of results
- Large molecular systems can be examined
- Little basis set dependence
- Variable accuracy, validation often necessary
- Systematic improvements not possible
$\qquad$ TJ K Gibbs- PhD Thesis 2008

### 1.2.6.5 Selection of Theoretical Method

The selection of a theoretical method for the study of a system is normally governed by economic and time constraints. Ordinarily, lower levels of theory are applied to basic structural optimisations of normal organic molecules. High levels of theory are generally applied to compounds or transition state modelling where structure specific interactions of electrons are important. The size of a molecule or the complexity of a system also governs the level of theory that can be used. Practicality dictates that only small molecules can be treated with the highest levels of theory, whereas huge protein molecules are frequently modelled with MMFF. It is for this reason that simplified structures are often used for theoretical calculations.

### 1.3 Mechanistic Studies of Iminium Ion Catalysed Processes

The primary objective of the majority of investigators in the field of organocatalysis has been the discovery of novel organocatalytic asymmetric reactions rather than development of existing methods. This approach is understandable given the vast potential of the field and its relative youth. A consequence of this is that mechanistic aspects of the reactions have been generally overlooked. The following section will highlighted the mechanistic studies that have been conducted within the field of iminium ion catalysis.

### 1.3.1 Structural Studies

The majority of publications in the field of iminium ion catalysis describe asymmetric transformations. Consequently, there is a mass of structural information through enantioenriched reaction products determined by crystallography and sophisticated NMR studies. The information obtained by determining the absolute configuration of reaction products has lead to numerous proposed transition state models and mechanisms with little supporting evidence. Transition state models based purely on structural information have been proposed for the enantioselective organocatalytic Diels-Alder, ${ }^{51}[2+2],{ }^{52}$ $[4+3],{ }^{53}[3+2]$ dipolar cycloadditions, ${ }^{54}$ Michael additions, ${ }^{55}$ hydrogenation, ${ }^{56}$ epoxidation, ${ }^{57}$ ene, ${ }^{58}$ Baylis-Hillman ${ }^{59}$ reactions along with numerous organocatalytic

Chapter 1 $\qquad$ TJ K Gibbs- PhD Thesis 2008 cascade processes. ${ }^{60}$ The reports that support mechanistic proposals based on structural studies with computational or thermodynamic studies are discussed under these headings.

The study of non-linear behaviour has been applied successfully within the field of enamine catalysis to reveal mechanistic insights. Non linear studies involving iminium ions have proved less successful. Hanessian conducted nonlinear studies for the Michael addition of nitroalkanes to cyclic enones using $L$-proline as the catalyst and piperazine derivatives as additives. ${ }^{61}$ A nonlinear effect was observed for the reaction using trans-2,5-dimethylpiperazine as an additive. Clear mechanistic conclusions could not be drawn as the system was complex, similar behaviour has, however, been reported for metal ligand based systems. ${ }^{62}$

### 1.3.2 Kinetic Studies

There are few reports of thermodynamic mechanistic investigations within the literature of iminium ion catalysis.

The most complete mechanistic investigation came form the group of Ogilvie who employed a combination of structural, kinetic and computational techniques to probe the mechanism of the organocatalysed Diels-Alder reaction with an asymmetric hydrazide catalyst 21 (Scheme 1.0). Ogilvie used ${ }^{1} \mathrm{H}$ NMR studies to detect and then observe the individual species in the catalytic cycle as the reaction proceeded. ${ }^{63}$ The kinetic evidence provided clearly indicated that the rate determining step of the catalytic cycle was the Diels-Alder cycloaddition reaction. It was also concluded that the hydrolysis step was rapid as the Diels-Alder cycloaddition iminium ion adducts 23 were not observed in significant quantities.

Chapter 1 $\qquad$

(Scheme 1.6)

Ogilvie subsequently isolated and crystallised the iminium ion intermediate 22 and combined this with PM3 semi-empirical computational studies to rationalise the favoured reactive conformation in solution. ${ }^{64}$

MacMillan undertook kinetic studies using ${ }^{1} \mathrm{H}$ and ${ }^{15} \mathrm{~N}$ NMR to explain the efficiency of [(nosylimino)iodo] benzene 30 as an in situ source of iodosobenzene 27 as an alternative to oligomeric iodosobenzene in an organocatalytic asymmetric epoxidation reaction. ${ }^{65}$

26

27

$-30^{\circ} \mathrm{C}$

29
(Scheme 1.7)

MacMillan used ${ }^{1} \mathrm{H}$ NMR studies to determine the rate of formation of 27 from $\mathbf{3 0}$ and from oligomeric iodosobenzene. The experiments clearly indicated that 27 formed much faster from oligomeric iodosobenzene (ca 35\% after 1h) and remained at a constant level for 6 h . The active oxidant $\mathbf{2 7}$ formed at a much slower rate from $\mathbf{3 0}$ steadily increasing to $15 \%$ conversion after 6 h .
$\qquad$

(Scheme 1.8)

Subsequent ${ }^{15} \mathrm{~N}$ NMR experiments demonstrated that compound 27 degenerated the reaction catalyst 28 resulting in compounds 31, 32 and 33 when oligomeric iodosobenzene was used as the source of oxidant 27 . However, when $\mathbf{3 0}$ was used as the oxidant precursor only decomposition product 32 was observed in comparatively minor concentrations.

(Scheme 1.9)

The work provided evidence that elegantly explained the increased reaction efficiency and levels of asymmetric induction observed when using $\mathbf{3 0}$ as the source of stoichiometric oxidant which was described as an 'internal syringe pump effect'. The results of this study demonstrated that the use of routine analytical tools can provide powerful evidence to rationalise experimental observations.

In a report on an asymmetric epoxidation reaction Córdova concluded that the reaction was possibly first order in respect to the pyrrolidine based catalyst $\mathbf{1 1}$ for catalyst loadings up to $10 \mathrm{~mol} \% .{ }^{66}$

(Scheme 1.10)

The reasons for his investigations are not entirely clear as the initial rates would be expected to be pseudo first-order in this process, independent of the true reaction order.
$\qquad$ TJ K Gibbs-PhD Thesis 2008

The rate constants are also plotted in unusual units and no information is published as to how the kinetic information was obtained.

### 1.3.3 Computational Studies

Theoretical studies represent the largest portion of mechanistic studies undertaken within the field of iminium ion catalysts. The primary role of these studies is to provide support and further refinement to existing proposals based on structural studies.

The level of theory and detail of the studies vary dramatically from simple low level molecular modelling which supports proposed intermediates to full theoretical papers calculating the relative energies of the species in the catalytic cycle concerned.

### 1.3.3.1 Molecular Mechanics Studies

The simplest molecular model employed for molecular modelling (CS Chem3D Pro ${ }^{\text {TM }}$ 4.0) was used by Karlson to provide relative energies of the reactive conformations of iminium ion intermediates in an asymmetric 1,3-dipolar cycloaddition reaction of nitrone 35 with $\alpha, \beta$-unsaturated aldehyde 34 (Scheme 1.11). ${ }^{67}$ Unsurprisingly, the application of the simplistic model to a complex reaction involving charged species led to ambiguous conclusions being drawn.

(Scheme 1.11)

The group of MacMillan have employed Monte Carlo (MC) simulations using the MM3 force field ${ }^{68}$ to rationalise the sense of asymmetric induction for a number of their imidazolidinone based catalysts 7,8 and 9 .
$\qquad$

7

8

9

38

39

40

The calculated structures are in agreement with the sense of asymetric induction observed in the reaction products. The conformation of iminium ion 38 has been used to rationalise the asymmetric Diels-Alder reaction, ${ }^{69}$ 1,3-dipolar cycloaddition ${ }^{70}$ and Michael addition of pyrrole ${ }^{71}$ with $\alpha, \beta$-unsaturated aldehydes. The conformation of iminium ion 39 has been used to rationalise the asymmetric Mukaiyama-Michael, ${ }^{72}$ Michael addition of indole ${ }^{73}$ and conjugate reduction reactions. ${ }^{74}$ Finally, the conformation of iminium ion 40 has been applied to explain the asymmetric induction of the Diels-Alder reaction with $\alpha, \beta$-unsaturated ketones. ${ }^{75}$ Subsequent to these reports higher level DFT calculations indicate that the structure of $\mathbf{3 8}$ may not be entirely correct (Figure 1.4). ${ }^{76}$ The correction however, does not, in this case, affect the sense of asymmetric induction and therefore is of limited importance. However, this does serve as a potent reminder that critical analysis of the considered choice of theoretical method is important.

(Figure 1.4) Left: MacMillan's calculated lowest energy conformation; Right: Calculated conformation reported by Houk.

Chapter
A further report of an MM study uses the MM3 force field to calculate the relative conformational energy of iminium ions, derived from imidazolidinone catalyst 9 and cyclopent-1-enecarbaldehyde, to explain the sense of asymmetric induction in a Michael addition reaction with substituted indoles (Scheme 1.12). ${ }^{77}$

(Scheme 1.12)

### 1.3.3.2 Semi Empirical Studies

Semi-empirical calculations have also been used to model iminium ion catalysed processes. The group of Jørgensen employed PM3 semi-empirical calculations to discover the minimum energy conformation of the iminium ion intermediate of the imidazoline based catalysts $\mathbf{1 0}$ and $\mathbf{4 4}$ to rationalise the asymmetry observed in a series of Michael additions to $\alpha, \beta$-unsaturated ketones.

10

43

44

The computationally determined structure of intermediate $\mathbf{4 3}$ has been used to explain the asymmetry observed for the Michael addition of nitroalkane ${ }^{16}$ and malonate ${ }^{78}$ nucleophiles. Intermediate iminium ion 45 and aminal 46 were modelled to explain the sense of induction observed when cyclic 1,3-dicarbonyl compounds were used as nucleophiles using 44 as the catalyst. ${ }^{79}$ Interestingly, both structures 45 and 46 are proposed as possible reactive intermediates. Furthermore, calculations indicated that the energy of the LUMO of 46 is activated when compared to the parent ketone.

Disappointingly, no further investigations to attempt to identify the actual catalytic species have been reported.

Nevalainen and co-workers also used PM3 calculations to provide supporting evidence for the favoured $E$-geometry of an iminium ion intermediate to rationalise the observed sense of asymmetric induction in an organocatalysed 1,3-dipolar cycloaddition reaction. ${ }^{80}$

The most detailed semi-empirical study using AM1 of iminium ion catalysed processes investigates the Diels-Alder reaction with protonated ammonia as a catalyst. ${ }^{81}$ The study investigated various reaction pathways indicating that cycloaddition across the $\mathrm{C}=\mathrm{C}$ bond was most favourable energetically.

(Scheme 1.13)

The study also found that the cycloaddition was a step-wise process, firstly forming an intermediate cation 48 followed by ring closure (Scheme 1.13). However, higher level calculations of reactive Diels-Alder systems have been conducted suggesting that the Diels-Alder cycloaddition although asynchronous is concerted. ${ }^{82}$ This demonstrates the pitfalls of theoretical chemistry when little thought is given to experimental evidence and oversimplified models are employed.

### 1.3.3.3 DFT Studies

DFT studies are the most detailed and frequently applied of the methods in the theoretical literature on iminium ion catalysis. The DFT studies reported are either detailed theoretical studies or are provided as supporting evidence for proposed transition states and intermediates.

The group of Houk have made several theoretical contributions to the field of organocatalysis. ${ }^{83}$ Detailed DFT (B3LYP) studies of MacMillan's asymmetric Diels-

Chapter I TJ K Gibbs- PhD Thesis 2008

Alder reaction ${ }^{84}$ and asymmetric Michael addition ${ }^{85}$ have been published. The calculated conformational energies of the corresponding reactive iminium ion intermediates and transition-states are obtained and applied to statistically predict the level of asymmetry observed. The studies correlate with experimental evidence and are therefore useful in mechanistic interpretation. Comprehensive and detailed studies such as these represent the bench mark for theoretical investigations within the field to date.

Subsequently, Uggerund published a detailed study validating the use of DFT for investigation of nucleophilic addition reactions to $\alpha, \beta$-unsaturated carbonyl compounds. ${ }^{86}$ The study involved comparison of high level ab initio calculations to the faster and cheaper DFT calculations. The study found that DFT (B3LYP) performed well and also revealed an unexpected intermediate $\mathbf{5 3}$ for the iminium ion catalysed Michael addition of nitromethane (Scheme 1.14).

(Scheme 1.14)

The study also found that protonated acrolein is more activated to nucleophilic attack than the corresponding iminium ion 51. This study highlights how detailed theoretical studies can provide interesting predictions which can be explored experimentally.

A DFT (B3LYP) study conducted by Platts examined the performance of numerous catalysts in key stages of the iminium ion catalysed Diels-Alder reaction. ${ }^{87}$ An energy profile for iminium ion formation was determined and the relative energies associated with a series of catalysts were calculated. The study found that the introduction of an $\alpha$-heteroatom and $\beta$-electron withdrawing group into acyclic catalysts lowered the activation barrier of iminium ion formation. The energy of the cycloaddition step was also measured and found to have a lower activation barrier than for iminium ion formation. The inclusion of an $\alpha$-heteroatom and a $\beta$-electron withdrawing group within the catalyst is known to accelerate the reaction when compared to standard catalysts and therefore it was suggested that the rate determining step may be iminium ion formation. ${ }^{88}$

Recently, Jørgensen has applied DFT (B3LYP) calculations rather than semi-empirical PM3 calculations to aid mechanistic understanding. The calculations were used to compare structural optimisations of reaction intermediates. The calculations identified the energetically favoured species to explain the observed asymmetry in the respective products for the Michael addition of a range of N -containing heterocycles ${ }^{89}$ and a domino Michael-aldol- $\mathrm{S}_{\mathrm{N}} 2$ reaction (Scheme 1.15). ${ }^{90}$ The computational results were consistent with the sense of asymmetric induction in both cases.

(Scheme 1.15)
The computations indicated that the formation of 54 in the ring forming intramolecular-aldol reaction was considerably more stable than 55 providing an explanation of the excellent levels of asymmetry observed (Scheme 1.15).

Córdova has used DFT to calculate possible theoretical transition-states and intermediates for an iminium ion catalysed hydrophosphination reaction to explain the observed enantioselectivity (Scheme 1.16). ${ }^{91}$

(Scheme 1.16)

The computations supported the hypothesis that the $E$-iminium ion was lower in energy than the $Z$-isomer, rationalising the observed asymmetry in intermediate 57. Compound 57 was however, not isolable and therefore was further elaborated in situ by oxidation to phosphine oxide 58 or treatment with $\mathrm{NaBH}_{4}$ to give the alcohol 59.

### 1.4 Conclusions

The potential for the discovery of novel asymmetric reactions or sequences within the field of iminium ion catalysis is vast. It is for this reason that the majority of leading researchers within the field pursue this goal. The discovery of novel methodology is of course important, however, there is a culture within the field that seeks only to display novel reactions or applications rather than to gain a thorough understanding of the reactions and their scope. Furthermore, there are several reasons why the organocatalytic methodology is not practical for widespread chemical manufacture at a large scale, notably, catalyst inefficiency and narrow substrate scope.

Within the field of iminium ion catalysis little effort has been deployed to understand the exact mode of action of the catalysts in the reactions. Frequently, groups postulate a transition-state based on structural studies of the reaction product and then use simple molecular modelling to provide supporting evidence. While in the majority of cases the transition states proposed seem perfectly viable, it is of extreme importance for future synthetic development that physical experiments are also conducted to validate the theory and provide a better mechanistic understanding.

The most thorough mechanistic study to date was conducted by Ogilvie who used a combination of techniques including qualitative kinetic measurements, structural studies and computational studies to gain a mechanistic insight. However, Oglivie's catalyst is considerably less efficient than others reported for the Diels-Alder reaction. Supporting theoretical studies investigated the mode of asymmetric induction rather than attempting to understand the low activity of the catalyst. From a developmental point of view the catalyst scaffold induces near perfect levels of asymmetry in the product therefore there is little room for improvement, whereas there is a significant potential to increase activity

Chapter 1 $\qquad$ TJ K Gibhs- PhD Thesis 2008
when compared to similar catalysts. This preoccupation with asymmetry is mirrored across the field of organocatalysis.

Kinetic and thermodynamic studies are the least represented of the mechanistic tools that have been used to investigate iminium ion catalysed processes, however, it is this class of study that will allow for a fundamental understanding of the catalytic processes. Development of more efficient catalysts to address the issues of low activity will be accelerated once sufficient mechanistic evidence is available to allow for rational design.

The lack of detailed mechanistic evidence for iminium ion catalysed processes is primarily a consequence of the infancy of the subject, encouraged by the fact that much kudos and consequently funding is given to large synthetic groups with high publication rates. Almost all the sub-disciplines of organocatalysis are fiercely competitive which might lead to a lack of mechanistic information being communicated and certainly promotes the culture of rapid publication and short-term investigations. With time, the field will mature and longer-term detailed studies will become more evident within the literature. Currently, the potential for detailed mechanistic investigations of organocatalytic transformations appears bright and exciting. It was these factors coupled with our curiosity, which provided the impetus for the investigations carried out within this thesis.

# Chapter 2: Investigations to Determine the Role of the $\beta$-EWG within Secondary Amine Catalysts Based Around the $\alpha$-Effect 

$\qquad$ TJ K Gibbs- PhD Thesis 2008

### 2.1 Introduction

### 2.1.1 The Aim of the Research

The overall goal of the research began as an attempt to develop novel, highly active catalysts for a range of asymmetric iminium ion catalysed processes.

### 2.1.2 Previous Work Within the Group

Work began within the group in an attempt to make more active catalysts for iminum ion catalysed transformations. ${ }^{92}$ Catalysts reported within the literature were of moderate activity presenting a developmental opportunity. The investigation began with the choice of the iminium ion catalysed Diels-Alder reaction as a tool to systematically improve catalyst design. The generalised catalytic cycle of this transformation is shown below (Figure 2.1).

(Figure 2.1)

The proposed catalytic cycle has three major components. The initial step is iminium ion formation, in which the secondary amine salt 65 condenses with the $\alpha, \beta$-unsaturated aldehyde 61 to yield the activated iminium ion 62. The iminium ion then undergoes a cycloaddition reaction with a diene such as cyclopentadiene 19 to yield the Diels-Alder iminium ion adduct 63. The cycle is complete when a molecule of water hydrolyses 63 to
yield the product of the reaction 64 and regenerate the amine 65 which can continue the catalytic cycle.

From the initial observation that all the effective catalysts reported in the literature contained a nucleophilic amine bound within a five-membered ring it was rationalised that the nucleophilicity of the amine was crucial to catalytic activity and that iminium ion formation was likely to be the rate determining step. ${ }^{93}$ Therefore, the group sought to find ways to increase the nucleophilicity of the amine and thus increase the catalytic activity. Work began to prepare a series of catalysts utilising the $\alpha$-effect to achieve this increased activity.

### 2.1.3 The $\alpha$-effect

The $\alpha$-effect can be defined as the increased nucleophilicity of a heteroatom by an adjacent heteroatom bearing a lone pair of electrons. The specific origin of this effect is not fully understood although many suggestions have been put forward. The two that are most widely accepted are:

- The interaction of the adjacent lone pairs leads to an increase in the energy of the HOMO of the nucleophile accelerating orbital controlled reactions. ${ }^{94}$
- The extra lone pair of electrons stabilises the transition state (stabilisation is substrate specific). ${ }^{95}$

Although a complete theoretical understanding of the $\alpha$-effect remains elusive, it is the $\alpha$-heteroatom's ability to increase reactivity that is of interest to the synthetic chemist and of which there can be no dispute. ${ }^{96}$

In order to allow direct comparison of a specific catalyst's activity the Diels-Alder cycloaddition between cinnamaldehyde 20 and cyclopentadiene 19 was used as a standard transformation.

(Scheme 2.1)

The catalysts that were initially investigated to determine if the $\alpha$-effect would accelerate the iminium ion catalysed Diels-Alder reaction were dimethylamine hydrochloride 65 as the standard, $N, N^{\prime}$-dimethylhydrazine dihydrochloride 66, $N, N^{\prime}$-diphenylhydrazine dihydrochloride 67 and $N, O$-dimethylhydroxylamine hydrochloride 68. On obtaining proof of principle more detailed studies would be warranted (Figure 2.2).

65

66

67

68
(Figure 2.2)

In the absence of catalyst and in the presence of $10 \mathrm{~mol} \%$ triethylamine hydrochloride the reaction of cinnamaldehyde 20 and cyclopentadiene 19 gave a $7 \%$ conversion after a 48 h period with predominance of the kinetically favoured endo-isomer 25. With dimethylamine hydrochloride 65, at a $10 \mathrm{~mol} \%$ loading, $22 \%$ conversion was observed with approximately $2: 1$ ratio of exo 24 to endo $\mathbf{2 5}$ isomer (the observation of this ratio is diagnostic of an iminium ion catalysed reaction). $N, N^{\prime}$-Dimethylhydrazine hydrochloride 66 and $N, N^{\prime}$-diphenylhydrazine hydrochloride 67 both demonstrated increased reactivity relative to the standard dimethylamine hydrochloride catalyst 65 ( $48 \%, 72 \mathrm{~h}$ and $33 \%, 48$ h, respectively). However, $\mathrm{N}, \mathrm{O}$-dimethylhydroxylamine hydrochloride 68 displayed a greater increase providing a $65 \%$ conversion under identical conditions. The results of this experiment clearly indicated that the $\alpha$-effect could be used as a tool to increase reactivity in iminium ion catalysis.

During this work another interesting observation was made when examining cyclic catalysts. Proline methyl ester hydrochloride 70 demonstrated superior activity to pyrrolidine hydrochloride 69 as a catalyst for the standard Diels-Alder reaction, suggesting that inclusion of a carbonyl group $\beta$ - to the reactive nitrogen could increase activity. With these results to hand the next stage was to develop catalysts based around the $\alpha$-effect to rival and compete with the reported cyclic catalysts in terms of efficiency.

71

7
(Figure 2.4)

The benchmark catalyst for this transformation is MacMillans catalyst 7 which facilitates a quantitative conversion for the standard Diels-Alder reaction after an 8 h period with excellent levels of asymmetric induction $\geq 90 \%$ e.e. ${ }^{14}$ The group began research to develop catalysts that could provide a more efficient catalyst than 7. The first step in the right direction was synthesis of catalyst $\mathbf{7 1}$ (Figure 2.4) which was prepared in two steps from commercially available ethyl carbazate and acetone. Catalyst $\mathbf{7 1}$ took the reaction between cinnamaldehyde 20 and cyclopentadiene 19 under the standard conditions to $93 \%$ after 48 h .

The success of these experiments led to a comprehensive structure activity relationship (SAR) study based around five variables of the newly developed catalytic architecture (Figure 2.5). ${ }^{97}$

(Figure 2.5)
The SAR resulted in numerous catalysts being prepared which allowed for many comparisons to be drawn, however, only the structural features important for activity will be highlighted. The SAR can be summarised with the following statements:

- The optimal $\alpha$-heteroatom $\mathbf{X}$ is nitrogen.
- The optimal co-acid is HCl .
- The optimal substitution $\alpha$ - to the reactive nitrogen is secondary $\left(\mathrm{R}^{1}\right)$.
- Optimal EWG is ethyl carbamate.
- Optimal substitution on the $\alpha$-heteroatom $X$ is tertiary $\left(\mathrm{R}^{2}\right)$.
- Most active catalyst scaffold was based around a six- membered ring.
- Catalysts based around five membered rings were ineffective.

Catalysts 72 and 73 were the optimal catalysts prepared for the cyclic and acyclic series respectively (Figure 2.6).

72

73
(Figure 2.6)

Catalyst 72 and 73 accelerated the standard Diels-Alder reaction to $86 \%$ and $89 \%$ conversion respectively after a 3 hour period at $10 \mathrm{~mol} \%$ loading.

The SAR study succeeded in producing more active catalysts than those reported in the literature for the Diels-Alder reaction. It was also observed that the $\beta$-EWG held a vital role in facilitating increased activity. However, it was not clearly apparent how the EWG increased the catalyst activity in the transformation. We therefore sought to make a series of catalysts that could generate information as to role of the EWG to aid our understanding of the $\alpha$-effect catalysts.

### 2.2 Results and Discussion

### 2.2.1 Separating the $\alpha$-effect and the $\beta$-EWG

The initial investigation sought to increase the reactivity of the catalysts by introduction of the $\alpha$-effect, however, this was only achieved by incorporation of a $\beta$-EWG, the role of which was not understood.

The first question that was addressd was whether the EWG was directly affecting the $\alpha$ heteroatom responsible for increasing the nucleophilicity of reactive nitrogen or was the effect independent? To provide an answer to this question we sought to include both structural features into a series of catalysts in a manner that would allow us to probe the role of the respective structural features. The structures 74, 75, 76 and 77 were proposed to achieve our aim.

74

75

76

77
(Figure 2.7)

The targets were chosen to allow direct comparison of structurally similar catalysts in the acyclic series. These targets also had the advantage that the synthesis was anticipated to be straightforward. Catalyst 74 allowed for separation of the $\alpha$-effect facilitated by a nitrogen atom remote from the $\beta$-EWG while catalyst 75 was prepared as the oxygen analogue of catalyst 74. Catalyst 76 allowed us to observe the effect of including an additional $\beta$-EWG on catalyst activity. Catalyst 77 was targeted as previous synthetic studies indicated that the increase in substitution $\alpha$ - to the reactive nitrogen should further increase activity.

(Scheme 2.2)

Synthesis of catalyst 74 was envisaged from condensation of $\mathrm{N}, \mathrm{N}$-dimethylhydrazine 79 with ethylglyoxylate $\mathbf{8 0}$ to afford the hydrazal $\mathbf{7 8}$ which could be subsequently selectively reduced to achieve the target 74 (Scheme 2.2). The other catalysts $\mathbf{7 5 - 7 7}$ were envisaged using similar methodology.

### 2.2.2 Synthesis of Catalysts

The synthesis of $\mathbf{7 4}$ proved to be difficult with many attempts needed to finally achieve the target compound in 5\% overall yield (Scheme 2.3). The initial condensation of the hydrazine $\mathbf{7 9}$ with ethyl glyoxylate $\mathbf{8 0}$ was efficient, although the imine intermediate was not rigorously purified. Considerable problems arose on reduction of the imine. Many methods were employed unsuccessfully including hydrogenation, reduction with sodium triacetoxyborohydride and sodium borohydride. Initially, sodium cyanoborohydride was unsuccessful, but finally granted access to the reduced catalyst 74 by increasing the number of equivalents of hydride to three and decreasing the pH of the reaction.

(Scheme 2.3)

The reaction proceeded with low conversion determined by ${ }^{1} \mathrm{H}$ NMR (ca $20 \%$ ) but the amount of compound obtained after purification was significantly lower than the conversion. A likely explanation for this is that the compound $\mathbf{7 4}$ has a low boiling point and therefore significant quantities were lost on concentration of the fractions after column chromatography. Despite this frustrating observation we were able to access sufficient quantities of $\mathbf{7 4}$ in order to examine its activity as an iminium ion catalyst.

Catalysts 75, 76, and 77 were synthesised in poor to average overall yields by a reductive animation procedure.

(Scheme 2.4)

### 2.2.3 The Standard Procedure for Analysing Catalyst Efficiency

To allow for direct comparison with previous work in the group a standard set of conditions was applied for the Diels-Alder cycloaddition (Scheme 2.5).

(i) Amine catalyst. $\mathrm{HCl}\left(10 \mathrm{~mol} \%\right.$ ), $\mathrm{MeOH}, 25^{\circ} \mathrm{C}, 24 \mathrm{~h}$ (ii) TFA, $\mathrm{CHCl}_{3}, \mathrm{H}_{2} \mathrm{O}, \mathrm{rt}, 16 \mathrm{~h}$
(Scheme 2.5)

The reaction was preformed in a set sequence. Initially $10 \mathrm{~mol} \%$ of catalyst was placed in methanol ( 2 mL ). To this was added the cinnamaldehyde $20(1 \mathrm{eq})$ and the reaction mixture allowed to stir for 2 minutes at $25^{\circ} \mathrm{C}$ before addition of cyclopentadiene 19 (2.5 eq). The reaction was promptly sealed and allowed to stir for a specific time. The starting time of the reaction was taken as the addition of cyclopentadiene 19. Upon completion of the reaction time the mixture was diluted with dichloromethane and reduced in vacuo to remove the cyclopentadiene 19 and hence terminate the reaction. Hydrolysis of the methyl acetals 86 and 87 was achieved by stirring in a TFA, water and chloroform mixture overnight. Neutralisation of the acidic solution followed by extraction gave the crude product for analysis. Further purification was possible with column chromatography but was not routinely conducted.

The conversion of the reaction was analysed using the crude product. This was possible as there were discreet and distinct peaks in the ${ }^{1} \mathrm{H}$ NMR spectrum which allowed for comparison of the ratio of product and starting material through integration. It had been shown that the signals corresponding to the exo-24 and endo- 25 isomers appeared at $\delta 9.85$ and $\delta 9.53$ respectively with cinnamaldehyde 20 at $\delta 9.64$ (Figure 2.8). ${ }^{98}$

(Figure 2.8) ${ }^{1} \mathrm{H}$ NMR spectrum of the region used to calculate conversion and exo:endo ratios for catalytic runs.

This method had previously been validated by comparison of the isolated yield of the experiment with those predicted from the conversion (determined by the method outlined above) being within experimental error ( $1-2 \%$ yield). ${ }^{99}$ There was no evidence of side reactions other than dimerisation of cyclopentadiene 19 which occured in a small and comparable extent in all catalytic runs independent of catalyst.

### 2.2.4 Performance of Catalysts

Catalysts were submitted to standard reaction conditions to gauge their respective activities (Tables 2.1 and 2.2).

(i) Catalyst ( $10 \mathrm{~mol} \%$ ), $\mathrm{MeOH}, 2{ }^{\circ} \mathrm{C}$. (ii) $\mathrm{TFA}, \mathrm{CHCl}_{3}, \mathrm{H}_{2} \mathrm{O}$

| Entry | Catalyst ${ }^{\text {a }}$ | Structure | Conversion \% ${ }^{\text {b }}$ | exo:endo |
| :---: | :---: | :---: | :---: | :---: |
| 1 | 74. HCl |  | 4 | n.d. |
| 2 | 75. HCl |  | 62 | 66:34 |
| 3 | 76. HCl |  | 65 | 65:35 |
| 4 | 77. HCl |  | 94 | 67:33 |
| 5 | 85. HCl |  | 94 | 65:35 |

(a) Reactions were carried out at $25^{\circ} \mathrm{C}$ for 6 hours with $10 \mathrm{~mol} \%$ catalyst in methanol.
(b) Conversion determined by ${ }^{1} \mathrm{H}$ NMR of crude reaction mixtures.
(c) exo/endo ratios determined by ${ }^{1} \mathrm{H}$ NMR of crude reaction mixtures.
(Table 2.1)

| Entry | Catalyst ${ }^{\text {a }}$ | Structure | Conversion \% ${ }^{\text {b }}$ | exo:endo |
| :---: | :---: | :---: | :---: | :---: |
| 1 | 74.HCl |  | 16 | 64:36 |
| 2 | 75. HCl |  | 83 | 66:34 |
| 3 | 76. HCl |  | 88 | 65:35 |
| 4 | 77. HCl |  | 94 | 67:33 |
| 5 | 85. HCl |  | 94 | 65:35 |

(a) Reactions were carried out at $25^{\circ} \mathrm{C}$ for 24 hours with $10 \mathrm{~mol} \%$ catalyst in methanol.
(b) Conversion determined by ${ }^{1} \mathrm{H}$ NMR of crude reaction mixtures.
(c) exdendo ratios determined by ${ }^{1} \mathrm{H}$ NMR of crude reaction mixtures.
(Table 2.2)

Hydrazine $74 . \mathrm{HCl}$ proved to be a disappointing catalyst for the reaction especially when compared with catalyst $\mathbf{7 5 . H C l}$. Catalyst 74 was difficult to synthesise with doubts over its stability. However, when the results from 6 h and 24 h are compared it suggests that the amount of compound catalysing the reaction remains constant as the conversion after $24 \mathrm{~h}(16 \%)$ is four times the magnitude of the conversion after $6 \mathrm{~h}(4 \%)$ which is expected in the early part of the kinetics for a first order process. A possible explanation in hindsight could be the formation of the dihydrochloride salt $\mathbf{8 8}$ which would severely alter the magnitude of the $\alpha$-effect as the lone pair believed to be responsible for increased nucleophilicity would be protonated and hence 88 would no longer posses the $\alpha$-effect. Due to the difficulties associated in the preparation of catalyst 74 investigations into whether this was the case were not conducted.

(Figure 2.9)
Catalyst 75 provided the most interesting results of those examined as it took the standard reaction to 62 and $83 \%$ conversion after 6 h and 24 h respectively. When catalyst 75.HCl was compared to catalysts $\mathbf{6 8}, 72$ and 70 interesting conclusions could be drawn (Table 2.3).

| Entry | Catalyst ${ }^{\text {a }}$ | Structure | Conversion \% ${ }^{\text {b }}$ | exo:endo |
| :---: | :---: | :---: | :---: | :---: |
| 1 | 75. HCl | $\text { H. } \mathrm{HCI} \text { İ }$ | 62 | 66:64 |
| 2 | 68 |  | <5 | n.d. |
| 3 | 89 | H.HCIII | <5 | 64:36 |
| 4 | 72 |  | 98 | 65:35 |
| 5 | 69 |  | <5 | n.d. |
| 6 | 70 |  | 62 | 70:30 |
| (a) Reactions were carried out at $25{ }^{\circ} \mathrm{C}$ for 24 hours with $10 \mathrm{~mol} \%$ catalyst in methanol. <br> (b) Conversion determined by ${ }^{1} \mathrm{H}$ NMR of crude reaction mixtures. <br> (c) exolendo ratios determined by ${ }^{1} \mathrm{H}$ NMR of crude reaction mixtures. <br> (Table 2.3) |  |  |  |  |

Catalysts 68 and 89 both contain less nucleophilic nitrogens and gave conversions less than $<5 \%$ after 6 h . Catalyst $75 . \mathrm{HCl}$ contains a nucleophilic nitrogen as well as $\beta$-EWG and is reasonably active (Table 2.3 , entry 1). Catalyst 72 (Table 2.3 , entry 4) is considerably more active than $\mathbf{7 5}$ but this can easily be attributed to superior structural features determined form the results of the previously conducted SAR study; namely the $\alpha$-heteroatom is nitrogen along with secondary substitution $\alpha$ - to the reactive nitrogen. Comparing this result with that of proline methyl ester hydrochloride 70 (Table 2.3, entry 6 ) and pyrrolidine hydrochloride 69 (Table 2.3, entry 5) it can be concluded that in order to have an active catalyst a nucleophilic nitrogen is required (achieved either by incorporation into a five membered ring or by utilising the $\alpha$-effect) along with a $\beta$-carbonyl based EWG. Importantly, these functionalities may be separated to obtain high activity.

Interestingly, incorporation of an additional EWG as in catalyst 76 (Table 2.2, entry 3) increases the conversion only slightly. With consideration of the structural differences
and previous SAR studies the catalysts can be thought of as having similar activity. This suggests that only a single $\beta$-EWG is necessary for efficient catalysis. The activities observed for catalysts 77 and 85 are consistent with the results of previous investigations. ${ }^{99}$

An explanation that would be consistent with the results obtained might be that the carbonyl in the $\beta$-position could be acting as a proton shuttle, aiding in the protonation and deprotonation of the various intermediates 81a and 81b involved in formation (and/or hydrolysis of iminium ion $\mathbf{8 4}$ (Scheme 2.7). If indeed it is these types of processes that are kinetically significant, then acceleration by a proton shuttling effect would increase the overall rate of iminium ion formation and hence the catalytic cycle, providing that iminium ion formation was the RDS.

(Scheme 2.7)

This model is consistent with the fact that the $\alpha$-heteroatom and the $\beta$-EWG can be separated spatially and with no loss of catalyst activity, and also the fact that a second $\beta$-EWG leads to no further gain in activity.

### 2.3 Conclusions

This study, along with previous investigations highlighted the need for both a nucleophilic nitrogen and a carbonyl based $\beta$-EWG within the catalyst architecture for high activity. The study also demonstrated that the two effects appeared to operate independently and therefore could be separated to allow for more structurally diverse catalysts to be designed. However, it was still unclear as to what was the mode of action of the $\beta$-EWG, despite the fact that synergy with the $\alpha$-effect could be eliminated.

# Chapter 3: Investigations to Discover the Function of the $\beta$-Electron Withdrawing Group 

### 3.1 Aim of the Investigation

The aim of this study was to synthesise a number of novel catalysts, based around the acyclic catalyst architecture developed previously within the group, to probe the optimal electronic properties for the $\beta$-carbonyl electron withdrawing group to increase catalyst activity. Appropriate electron withdrawing/donating groups were introduced to allow for a Hammett plot to be obtained.

### 3.2 Introduction

The results of previous experiments lead us to hypothesise that the $\beta$-EWG was acting as a proton shuttle in iminium ion formation and thus increasing the efficiency of iminium ion formation and hydrolysis, accelerating the catalytic cycle. We sought to provide evidence for this mode of action and attempted to tune the electronics of the $\beta$-EWG to provide more active catalysts, while providing information to aid future rational design of chiral catalysts.

To provide supporting evidence for our hypothesis we designed an SAR study in which variation of the electron density centred on the carbonyl might provide more active catalysts and further our understanding. Considered choice of the catalyst scaffold to be modified would allow us to construct Hammett plots by relating the pseudo first order rate constants of the overall catalytic cycle to the Hammett parameters of the substituents.

### 3.2.1 Catalyst Design

The catalyst scaffolds chosen for elaboration were 90 and 91 . The reasons for this were three fold: Firstly, the catalysts had moderate activity over a 6 h period ( $76 \%$ and $58 \%$ conversion respectively) which would allow for any alteration in activity to be easily observed. Secondly, synthesis of the catalysts was envisaged to be short and straightforward. Finally, electronically perturbing substituents placed on the benzoyl EWG groups allow for Hammett analysis to be conducted.

90

91
(Figure 3.1)

The catalysts chosen as targets were designed to include a range of stronger and milder $\beta$-EWG relative to the standard catalysts 90 and 91 . We also targeted catalysts that could not be used in a Hammett plot but would allow qualitative conclusions to be drawn about the nature of the $\beta$-EWG.

(Figure 3.2)

Catalysts 90 and $\mathbf{9 5 - 9 9}$ were targets for the Hammett analysis. Catalysts 92 and 94 were designed to replace the oxygen of the carbonyl with a sulphur atom to explore the effect on catalyst activity. Catalyst $\mathbf{9 3}$ was chosen to investigate the effect of a strong electron donating group on activity.
$\qquad$

### 3.3 Results and Discussion

### 3.3.1 Synthesis

Synthesis began with formation of hydrazone 100 from the condensation of acetone and N -methylhydrazine 101 ( $70 \%$ ) followed by coupling with the corresponding acid chloride to yield the catalyst precursor which was subsequently reduced to yield the target catalysts in yields of 13-73\% from 100.

[^0] (ix) 5 eq HCl in ether, ( x ) HCl salt formed in reaction vessel with HCl in MeOH , (xi) $\mathrm{H}_{2}, \mathrm{PtO}_{2}, \mathrm{EtOH}, 16 \mathrm{~h}$

Compound 93 was synthesised in an analogous manner coupling the hydrazone 100 and phenyl isocyanate followed by reduction to yield the free base of the catalyst (Scheme 3.2). Synthesis of $\mathbf{9 4}$ was attempted, however, difficulties were encountered in the purification with minor but detectible impurities present. No further studies were performed with catalyst 94.

(i) $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, rt, 16 h , (ii) $\mathrm{NaCNBH}_{3}, 2 \mathrm{~N} \mathrm{HCl}, \mathrm{MeOH}, 16 \mathrm{~h}$, (iii) 5 eq HCl in MeOH
(Scheme 3.2)

Catalyst 91 was synthesised from commercially available benzoic hydrazide 102 and acetone to yield hydrazide 103 followed by a reduction and salt formation to give 91 (Scheme 3.3). ${ }^{100}$

(i) $\mathrm{CH}_{3} \mathrm{CN}, \mathrm{rt}, 16 \mathrm{~h}$, (ii) $\mathrm{H}_{2}, \mathrm{PtO}_{2}, \mathrm{EtOH}, 16 \mathrm{~h}$, (iii) 5 eq HCl in ether
(Scheme 3.3)

Catalyst $\mathbf{9 2}$ was synthesised from compound $\mathbf{1 0 3}$ using Lawesson's reagent to convert the carbonyl to the corresponding thio carbonyl. The product was reduced and the salt formed to yield the catalyst 92 (Scheme 3.4).

(i) Lawesson's reagent, $\mathrm{CH}_{3} \mathrm{Ph}, \Delta, \mathrm{N}_{2}, 16 \mathrm{~h}$, (ii) $\mathrm{NaCNBH}_{3}, 2 \mathrm{M} \mathrm{HCl}, \mathrm{MeOH}, 16 \mathrm{~h}$, (iii) 5 eq HCl in ether
(Scheme 3.4)

The salts of all the catalysts (except 97) were formed on adding 5 equivalents of HCl in methanol to the free base. The salt of 97 was generated in situ for the catalytic run by adding a single equivalent of HCl in MeOH of known concentration. This method was validated by comparing the performance of the free base of catalyst 91 , forming the salt in situ, with that of the preformed HCl salt. The results were found to be within experimental error (ca 3\%) confirming the validity of this method. This was necessary to allow for direct comparison with experiments previously conducted.

### 3.3.2 Catalyst Performance

Once the catalysts were prepared they were examined in the standard Diels-Alder reaction between cinnamaldehyde 20 and cyclopentadiene 19 for $6 h$.

(Scheme 3.5)
Entry Catalyst $^{\text {a }}$
(Table 3.1)

The results of this study yielded some interesting but overall disappointing results. The catalyst with the lowest activity was 92 (entry $3,<5 \%$ ). The reaction appeared extremely sluggish, especially when compared to the equivalent catalyst 91 (entry $2,58 \%$ ), such
that after a 6 h period insufficient product was formed to enable measurement of an exo:endo ratio. It is noteworthy, however, that the ${ }^{1} \mathrm{H}$ NMR spectrum of the reaction mixture indicated that some other process may have occurred as it appeared uncharacteristically complex and untidy. Whether or not the catalyst was just poor or had reacted in a different manner was not defined, however, it can be concluded that thiocarbamate EWG's were not effective within the catalyst scaffold for this transformation.

The introduction of a urea based EWG in catalyst 93 had a detrimental effect on catalyst activity (entry 4, 25\%) when compared to standard catalyst 90 (entry 1, 76\%). The urea group was chosen for the high electron density that would be present on the carbonyl from donation of the lone pairs of the nitrogens. It was concluded that this effect was possibly too strong for optimal catalyst activity.

The catalysts designed to have lower electron density on the carbonyl of the EWG displayed a mixture of results. Catalyst 97 (entry 7, 52\%) gave the lowest conversion followed by 96 (entry 6, 61\%). Catalyst 99 (entry 9, 77\%) displayed similar activity to the standard 90 (entry 1, 76\%). It is clear from these results that apart from commenting on individual catalysts there was no apparent relationship between electron density on the carbonyl oxygen and catalyst activity.

The catalysts designed to have greater electron density on the carbonyl also provided inconclusive results. Catalysts 95 (entry 5, 75\%) and 98 (entry 8, 77\%) both gave conversions that were within experimental error of the standard catalyst 90 (entry 1,76\%) and therefore it can be concluded that these subtle changes in the electron density had no significant effect on reactivity.

Originally, the catalysts were designed to construct a Hammett analysis to yield information of the electronic environment of the key transition-state in the overall catalytic cycle. However, it is clear from the results (Table 3.1) that there was no
relationship between catalyst activity and electron withdrawing ability, therefore, a Hammett analysis was not conducted.

In parallel to this work on acyclic catalysts another group member conducted a similar study based on a cyclic catalyst scaffold (Table 3.2). ${ }^{99}$

| Entry | Catalyst ${ }^{\text {a }}$ | Structure | Time h | Conversion \% ${ }^{\text {b }}$ | exo:endo ${ }^{\text {c }}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 105 |  | 6 | 67 | 66:34 |
| 2 | 106 |  | 6 | 59 | 64:36 |
| 3 | 107 |  | 6 | 32 | 62:38 |
| 4 | 108 |  | 6 | 17 | 50:50 |
| 5 | 109 |  | 6 | 15 | 32:68 |
| 6 | 110 |  | 6 | 35 | 69:31 |
| 7 | 73 |  | 6 | 99 | 68:32 |
| 8 | 111 |  | 6 | 94 | 68:32 |

(a) Reactions were carried out at $25^{\circ} \mathrm{C}$ for 24 hours with $10 \mathrm{~mol} \%$ catalyst in methanol.
(b) Conversion determined by ${ }^{1} \mathrm{H}$ NMR of crude reaction mixtures.
(c) exdendo ratios determined by ${ }^{1} \mathrm{H}$ NMR of crude reaction mixtures.
(Table 3.2)

The results obtained for the cyclic series were in good agreement with the acyclic series. Catalysts based on thiocarbamates 110 (entry 6, 35\%) and urea derivatives 109 (entry 5, 15\%) and 108 (entry 4, 17\%) performed badly compared to standard catalyst 106 (entry 2,59\%). However, a small but significant increase was observed for the slightly electron donating $p$-methoxyphenyl catalyst 105 (entry 1, 67\%) relative to standard catalyst 106 (entry 2, 59\%). The catalyst containing a $p$-nitro EWG displayed reduced activity compared to standard catalyst 106 (entry $3,32 \%$ ).

The number of catalyst synthesised suitable for Hammett analysis was insufficient although the limited results looked promising. It is noteworthy, however, that none of the catalysts prepared had comparable activity to the previously synthesised benchmark catalyst 73 (entry 1, 99\%). The study managed to discount numerous structural features for future design but provided little information that could be applied to enhance catalyst activity.
$\qquad$

### 3.3.3 The Role of the Electron Withdrawing Group EWG

An important question that needed to be addressed to aid our understanding was whether the $\beta$-EWG must be carbonyl based to be effective. Therefore, we sought a commercially available catalyst that contained a nucleophilic nitrogen but also a strong $\beta$-EWG that could not act as a proton shuttle. Trifluoromethyl pyrrolidine (112) was selected as it would allow direct comparison with pyrrolidine hydrochloride (69) and proline methyl ester hydrochloride (70). The trifluoromethyl group is a very strong EWG but the fluorine atoms should not act as a proton shuttle. Catalyst 112 was converted to the HCl salt 112. HCl and examined in the standard Diels-Alder reaction.

(Table 3.3)

Catalyst $112 . \mathrm{HCl}(93 \%, 6 \mathrm{~h})$ was surprisingly active, especially given the fact that it had a simple structure compared to the more elaborate catalysts that we had prepared of similar activity. This result suggested that the $\beta$-EWG was acting on a purely inductive basis as it was difficult to envisage any other mode of action. We therefore concluded that ability of the $\beta$-EWG to act as a proton shuttle could also be excluded as an important feature in catalyst design.

The significant conclusion was that our understanding of the role of the $\beta$-EWG was inadequate. The underlying reason for this was that we had a poor understanding of the relationship of the individual steps of the catalytic cycle. This lack of knowledge made it extremely difficult to arrive at credible conclusions because our deductions to date were based largely on qualitative experiments.

### 3.4. Conclusions

Our attempts to prepare more active catalyst for the iminium ion catalysed Diels-Alder reaction by altering the electron density of the carbonyl group failed. Each of the novel catalysts prepared were of lower activity to catalysts previously prepared within the group. The catalysts prepared were designed to probe the electronic requirements of the carbonyl based $\beta$-EWG, however, due to the spread of results obtained, this was not possible. The effectiveness of trifluoromethyl pyrrolidine hydrochloride $\mathbf{1 1 2} . \mathrm{HCl}$ as a catalyst suggested that the $\beta$-EWG was not exclusively acting as a proton shuttle as previously hypothesised. It was also concluded that detailed investigations into the mechanism of the catalytic cycle should be conducted to achieve a better appreciation of the relationships of catalyst architecture and activity.

# Chapter 4: Studies to Determine the Mechanism of the Organocatalysed Diels-Alder Reaction 

### 4.1 The Aim of the Research

The purpose of this investigation was to establish the kinetically important features within the catalytic cycle by measurement of the rate constants and activation energies associated with each step. We also sought to extract any additional information that would aid us in the rational design of secondary amine catalysts for the Diels-Alder reaction.

### 4.2 Introduction

Having spent much effort within the group developing and testing catalysts for the DielsAlder reaction between cinnamaldehyde 20 and cyclopentadiene 19 it was evident that our conclusions were philosophically weak due to our inherent ignorance of the physical parameters of the catalytic cycle.

(i) Catalyst ( $10 \mathrm{~mol} \%$ ), $\mathrm{MeOH}, 25^{\circ}$ С. (ii) TFA, $\mathrm{CHCl}_{3}, \mathrm{H}_{2} \mathrm{O}$
(Scheme 4.1)

To aid in the interpretation and also development of catalysts we sought to discover the relative rates and activation energies associated with the individual steps of the catalytic cycle. Previous attempts to understand the mechanism had been undertaken within the group and a range of techniques had been applied to gain an insight. ${ }^{99}$ These attempts failed to provide any quantitative evidence for the mechanism but provided a solid platform from which to expand the research.

The previous work was thwarted by the inability to isolate iminium ions to allow for independent study of the individual steps of the reaction. To further this research we targeted the isolation of the iminium ion intermediate as the key task to unlock the kinetics of the reaction.

Concurrent with our investigations Ogilive published similar work based on the kinetic observation of his asymmetric $\alpha$-effect catalyst 24 . The study comprised of monitoring the entire catalytic cycle by ${ }^{1} \mathrm{H}$ NMR and observing the relative quantities of the various intermediates against time. From the data obtained it was possible to identify the rate determining step which was highlighted as the Diels-Alder cycloaddition. However, as quantitative kinetic measurements were not conducted, no explanation could be given to explain the observation. From our preliminary studies we could postulate that the RDS was the Diels-Alder cycloaddition step form the observation that it was sluggish relative to the other steps in the catalytic cycle. Furthermore, Ogilive's catalyst, although asymmetric was not very active and the reactions were conducted in nitromethane and therefore, could have very different kinetics to the systems that were of interest to us. The publication, although elegant, failed to provide any of the explanations that we sought to further our understanding of the catalytic cycle. Therefore, we continued with our studies with a hope to satisfy our curiosity.

### 4.2.1 The Concept

(Figure 4.1)

The isolation or favourable equilibrium in solution of an intermediate iminium ion $\mathbf{1 1 5}$ would allow for the determination of the kinetics for the formation of the iminium ion if a suitable physical technique could be found (Scheme 4.2).

Chapter 4

The isolation of 115 would also allow for a subsequent independent reaction with cyclopentadiene 19 to form Diels-Alder iminium ion adduct 116 (and its endo-isomer). Under anhydrous conditions the isolation of compound 116 should also be possible (Scheme 4.3).

The isolation of Diels-Alder iminium adduct 116 would also allow for the independent study of step 3 on addition of water (Scheme 4.4).

The combination of the three steps would allow us to build up a picture of the entire catalytic cycle to aid in our understanding and the quest for more active catalysts.

### 4.3 Results and Discussion

### 4.3.1 Isolation of Iminium Ions

Previous attempts to isolate iminium ions as their HCl salts had proved unfruitful, indicating that modification of the system was necessary to achieve our aims. We therefore sought a catalyst-dienophile-co-acid combination that would provide a stable iminium ion (Figure 4.2).

(Figure 4.2)

We began our search by identifying catalysts that would, from our experience, provide a practical and useful system for kinetic evaluation. We rationalised that we should select an active catalyst that we had previously studied on the bench, as the relative order of kinetics for each step might be different for less active catalysts (it was of course the active catalysts that interested us most). Also, the collection of data would be more rapid with an efficient system. The catalysts selected were trifluoromethyl pyrrolidine 112, MacMillan's imidazolidinone 7 and the most active catalyst developed by the group to date 73 (Figure 4.3).

112

7

73
(Figure 4.3)

Our intention was to use either cinnamaldehyde $\mathbf{2 0}$ or its derivatives $\mathbf{1 1 7 - 1 2 1}$ as our dieneophile to ensure that our model system was as similar as possible to the system we had used for our SAR studies (Figure 4.4).

Chapter 4 $\qquad$

20

117

118

119

120

121
(Figure 4.4)

Compounds 117 and 118 were chosen as substrates for use with fluorescence spectroscopy as they are known fluorophores. 117 and 118 were synthesised via a literature Heck reaction. ${ }^{101}$ The remaining aldehydes $\mathbf{1 1 9 - 1 2 1}$ were commercially available.

It was clear that the one aspect of our system that needed addressing was the co-acid as numerous attempts to isolate the iminium chloride salts had failed. This was believed to be due to their instability towards hydrolysis. We therefore sought a co-acid that might have a stabilising effect on the resulting iminium ion. To achieve this we selected a number of weakly coordinating anions highlighted as good candidates in a review of noncoordinating anions. ${ }^{102}$ We selected hexafluorophosphoric acid $\mathrm{HPF}_{6}$, tetrafluoroboronic acid $\mathrm{HBF}_{4}$ and fluoroantimonic acid $\mathrm{HSbF}_{6}$. Pleasingly, on reaction of one equivalent of cinnamaldehyde 20, trifluoromethyl pyrrolidine 112 and aqueous $\mathrm{HPF}_{6}$ in methanol at room temperature we obtained the iminium ion 122 in $82 \%$ yield as a geometrically pure bench stable compound.

(Scheme 4.5)
This initial success allowed us to synthesise a range of iminium ions based on catalysts 112 and 7 with a variety of cinnamaldehyde derivatives and co-acids. These iminium ions were primarily characterised by HRMS and occasionally X-ray diffraction as in solution the majority of iminium ions were clearly in equilibrium with the starting materials making spectroscopic analysis difficult. Full analysis was conducted for the iminium ion 122 which was important to the study.
$\mathrm{HPF}_{6}$ quickly emerged as the optimal co-acid for the isolable iminium ions although $\mathrm{HBF}_{4}$ and $\mathrm{HSbF}_{6}$ did yield iminium ions, but they appeared to be less stable than those derived from $\mathrm{HPF}_{6}$. Catalyst $\mathbf{1 1 2}$ gave the most stable iminium ions isolated and therefore was selected for subsequent kinetic studies.

### 4.3.2 Structural Studies

Having synthesised numerous examples of stable iminium ions we attempted to grow crystals suitable for X-ray analysis. The iminium ions for which X-ray structures were determined are shown below (Figure 4.5).

It was hoped that a comparison of structural features of the isolated iminium ions and their relative activity would structuaral information that could be related to the electronic of the $\pi$-system. A selection of these structures are shown below (Figure 4.6). These Xray structures clearly show that the $E$-geometry is favoured for iminium ions $\mathbf{1 2 4}$ and $\mathbf{1 2 2}$ and that in all iminium ions the $\pi$-system is planar indicating good conjugation. The X ray structures also provided structural information about the catalyst conformation in the iminium ion providing a more accurate model from which to design asymmetric catalysts. We have used the approach to investigate a novel class of secondary amines to be developed as asymmetric catalyst for iminium ion catalysed processes (see Chapter 6).

124

122

123
(Figure 4.6) From left to right: X-ray structures of 124, 122 and 123

The isolation of the MacMillan derived iminium ion 124 allowed comparison of the solid-state structure with the two published calculated structures (MacMillan 124a ${ }^{103}$ and Houk $\mathbf{1 2 4 b} \mathbf{b}^{104}$ ) and a calculated structure obtained during complementary theoretical studies conducted by Platts and Evans in Cardiff. ${ }^{105}$ The structure reported by Houk was remarkably similar to the structure obtained from Evans's calculations and thus only the Evans structure of the two is shown (124b).

(Figure 4.7) From left to right: MacMillan's calculated structure 124a, Evans calculated structure $\mathbf{1 2 4 b}$ and X-ray structure 124.

This evidence suggests that the structure proposed by MacMillan using low level MM3 calculations in which $\pi-\pi$ stacking localises the benzyl arm over the iminium ion is incorrect in the solid-state. The most likely structure is the benzyl arm residing over the centre of the imidazolidinone ring of the catalyst 124 (Figure 4.7). However, the argument is academic as the mode of asymmetric induction is consistent for both conformations.

The direct comparison of the experimentally obtained and calculated structures of iminium ion 124 display remarkable similarity when comparing the conformation of the benzyl group. The observed difference in the planarity of the iminium ion itself can be explained by coordination of the $\mathrm{PF}_{6}$ anion in the solid state which has been removed for clarity (Figure 4.8).

(Figure 4.8) Displaying the X-Ray 124 and the Evans calculated structures 124b overlaid.

Having established that isolation of iminium ions was possible and fairly general for cyclic secondary amines with cinnamaldehyde derivatives and $\mathrm{HPF}_{6}$, we sought to identify the technique that would be most useful for determining the kinetics of the individual steps of the catalytic cycle.

### 4.3.3 Establishing a Physical Technique for Kinetic Analysis

The work previously conducted by Jones ${ }^{99}$ suggested that UV spectroscopy would be a useful technique. We were also aware that fluorescence spectroscopy was a similar technique with departmental expertise to aid the physical studies. To explore this avenue we synthesised reported cinnamaldehyde derivatives $\mathbf{1 1 7}$ and $\mathbf{1 1 8}$ with fluorescent tags by a Heck reaction between the aryl halide and acrolein ethyl acetal followed by acetal hydrolysis. Subsequently we formed the corresponding iminium ions using $\mathrm{HPF}_{6}$ and trifluoromethyl pyrrolidine 112.

It was clear from preliminary experiments that low concentrations were needed for UV and fluorescence spectroscopy which favoured the starting materials $\mathbf{2 0}$ and 112. $\mathrm{HPF}_{6}$ in the equilibrium of step 1 (Scheme 4.6). The reason for this was that on dilution of the solution containing iminium ion $\mathbf{1 2 2}$ the relative amount of water present was drastically increased using bench solvents. This amount of water essentially made the hydrolysis reaction pseudo $1^{\text {st }}$ order and hence independent of the concentration of the iminium ion, where as the forward iminium ion formation reaction was still a concentration dependant $2^{\text {nd }}$ order reaction as the reactants were present in equimolar amounts. This observation highlighted that use of these spectroscopic techniques would require significant experimental effort and development to be useful, and therefore, we investigated NMR as an experimental technique.

(Scheme 4.6)

Jones had previously discounted ${ }^{1} \mathrm{H}$ NMR as a useful technique as it appeared that the majority of the reaction had taken place before the first physical measurement could be made at approximately 7 minutes after mixing. We rationalised however, that reducing the concentration would decrease the actual rate of reaction and allow for physical measurements to be conducted. Furthermore, technical consultation indicated that methods were available for more rapid measurement of data points. Knowing this, qualitative experiments were conducted which clearly indicated that ${ }^{1} \mathrm{H}$ NMR would be a useful tool for the measurement of kinetics of iminium ion formation and of the subsequent Diels-Alder cycloaddition. The conditions and experimental details used are discussed in the following section.

### 4.3.4 Choice of Solvent for Study

The solvents of choice for the iminium ion catalysed Diels-Alder reaction for the majority of active catalysts are MeOH or $\mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O}$ mixtures. However, mechanistic studies involving these solvents would be complex as the aldehydes in the reaction would be in equilibrium with their corresponding methyl acetals causing complications (Scheme 4.7).

(Scheme 4.7)

If the reaction were to be conducted in MeOH then it would add extra equilibria to the catalytic cycle and thus create an additional level of complexity (Scheme 4.7). To circumvent this problem we sought a solvent that would maintain reactivity but would not react with the aldehydes and iminium ions in the reaction. The solvent would also have to be available in its deuterated form to be of use in NMR studies. Conducting a solvent screen revealed $\mathrm{CH}_{3} \mathrm{CN}$ as the optimal reaction medium as it facilitated the fastest reaction for a non-alcoholic solvent. ${ }^{106}$ Subsequently, it was found that the iminium ion of our model system $\mathbf{1 2 2}$ was only soluble in $\mathrm{CH}_{3} \mathrm{CN}$ reinforcing our choice of solvent.

### 4.3.5 Validation of Model System

The components of our model system differ from those we would use to conduct the reaction on the bench. Therefore it was important to validate our model system by performing a bench reaction and then compare observations with the optimal system.

Comparison of the $\mathrm{HPF}_{6}$ and HCl counter co-acids in methanol was not possible as the use of $\mathrm{HPF}_{6}$ co-acid caused precipitation of the iminium ion 122 in the reaction vessel thus removing the active component from the catalytic cycle. We therefore conducted a reaction on the bench with $\mathrm{HPF}_{6}$ in acetonitrile which gave $56 \%$ conversion in 6 h compared to HCl in methanol $93 \%$ in 6 h . Considering that we had moved form the optimal solvent and co-acid the drop in reactivity was expected.

No significant by-products were observed in the ${ }^{1} \mathrm{H}$ NMR of the crude reaction mixture consistent with the standard reactions. This evidence suggested that alteration of the coacid affects the rate of the reaction but did not effect the mechanics of the reaction. Therefore, conclusions drawn from study of the model system should be applicable to the optimal bench system.

### 4.3.6 Iminium Ion Formation Step 1

We used the distinct ${ }^{1} \mathrm{H}$ NMR signal of the cinnamaldehyde 20 at 9.65 ppm and the iminum ion 122 at 8.64 ppm to allow us to monitor the progress of the reaction (Figure 4.9). Using the integrations of the peaks we could quantitatively determine the conversion of the reaction. The conversion was then related to concentration at any data point as the initial concentrations were known. This allowed us to extract the second order rate constant $k_{\text {imin }}$ from a plot of $1 /[\mathrm{A}]$ vs t (Appendix) (where [ A ] is the concentration of the cinnamaldehyde) (Appendix).

Chapter 4 $\qquad$

(Figure 4.9)

We measured the rate constants at 293, 298 and 303 K (in duplicate) to allow the construction of an Arrhenius plot and hence determination of the activation energy. The rate constant was found to be $2.65 \pm 0.35 \times 10^{-3} \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$ at 293 K .

(Figure 4.10)
Measuring the rate constants at different temperatures allowed us to plot $\ln k_{\mathrm{imin}}$ vs $1 / \mathrm{T}$ to obtain the $E_{a}$ for step 1 at $100.0 \pm 7.9 \mathrm{~kJ} \mathrm{~mol}^{-1}$ with an associated Arrhenius parameter A
of $6.694 \times 10^{15} \mathrm{~s}^{-1}$. The error on the intercept for the linear fit is $\pm 3.17$ leading t a uncertainty of $\pm e^{3.17}$ (Figure 4.8). (For experimental data see Appendix)

### 4.3.7 Diels -Alder Cycloaddition Step 2

The Bruker 500 MHz NMR machine was also employed for similar measurements of the Diels-Alder cycloaddition step. Ideally, we wanted to study steps 2 and 3 separately, however, this was not possible using our model system as the ${ }^{1} \mathrm{H}$ NMR signals of the Diels-Alder iminium ion adducts $\mathbf{1 3 0}$ and $\mathbf{1 3 1}$ overlapped with those of the iminium ion $\mathbf{1 2 2}$ at 8.64 ppm . Furthermore, the Diels-Alder iminium adducts $\mathbf{1 3 0}$ and $\mathbf{1 3 1}$ were observed to convert to side products corresponding to new unidentified broad peaks in the NMR signal at 9.21 and 9.33 ppm (Scheme 4.8). The reaction to these new unidentified peaks was not reversible by addition of 2 equivalents of water over a period of an hour (see Appendix).

We had strong evidence that the hydrolysis of the Diels-Alder iminium ion adducts $\mathbf{1 3 0}$ and 131 was extremely rapid relative to the Diels-Alder cycloaddition: When 2 equivalents of water were added to a $\mathrm{CH}_{3} \mathrm{CN}$ solution of $\mathbf{1 2 2}$ followed by addition of $\mathbf{1 9}$, the only observable peaks in the ${ }^{1} \mathrm{H}$ NMR were the Diels-Alder adducts 24 and 25 (Figure 4.11). No indication of the intermediate iminium ions $\mathbf{1 3 0}$ and $\mathbf{1 3 1}$ could be detected. The absence of the unidentified peaks at 9.21 and 9.33 ppm in any of the reactions carried out in the presence of water in an NMR tube and on the bench suggested that there was never a sufficent amount of Diels-Alder iminium adduct formed in solution to facilitate this side reaction that was readily observed in absence of water. Furthermore, in the actual bench reactions MeOH or $\mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O}$ (19:1) are used as solvents so there are huge excesses of methanol and water present to hydrolyse the Diels-Alder iminium adducts 130 and $\mathbf{1 3 1}$ greatly reducing the kinetic significance of this step.

With 2 equivalents of water the reaction that we were effectively observing was the conversion of iminium ion $\mathbf{1 2 2}$ at ( 8.64 ppm ) to the Diels-Alder products 24 and $\mathbf{2 5}$ (9.84 and 9.53 ppm respectively).

(Scheme 4.9)
Confident that the rate of hydrolysis was rapid compared to the cycloaddition we can state that our $\mathrm{k}_{\mathrm{obs}}=\mathrm{k}_{\mathrm{DA}}$. We then went on to measure the rate constants at a series of temperatures to allow us to calculate the Arrhenius parameter $A$ and activation energy $E_{a}$.

To allow for practical measurement 2.5 equivalents of cyclopentadiene were used as this accelerated the reaction to allow observation of the important portion of the kinetics within a one hour period. This treatment complicated the mathematics slightly but was easily manageable (see Appendix).

(Figure 4.12)
The second order rate constant of the Diels-Alder transformation was determined at 293, 298 and 303 K . The rate constant $\mathrm{k}_{\mathrm{DA}}$ was found to be $3.74 \pm 0.02 \times 10^{-4} \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$ at 293 K . The $E_{a}$ for the Diels-Alder cycloaddition was found to be $E_{a}=45.1 \pm 1.7 \mathrm{~kJ} \mathrm{~mol}^{-1}$
with an associated Arrhenius parameter value of $4.14 \times 10^{4} \mathrm{~s}^{-1}$ with an uncertainity of $\pm e^{0.17}$ (Figure 4.12).

### 4.3.8 Comparison to Theoretical Data

To compliment the experimental work Evans and Platts performed theoretical calculations to determine the activation energy of the individual steps of the catalytic cycle. ${ }^{107}$ A comparison of the experimentally determined and calculated values for the $E_{a}$ are shown below (Table 4.2).

| Step | Experimental $\mathrm{E}_{\mathrm{a}}$ <br> $\left(\mathrm{kJ} \mathrm{mol}^{-1}\right)$ | Theoretical $\mathrm{E}_{\mathrm{a}}$ <br> $\left(\mathrm{kJ} \mathrm{mol}^{-1}\right)$ |
| :---: | :---: | :---: |
| Iminium ion formation 1 <br> Diels-Alder cycloaddition <br> 2 | $45.1 \pm 1.7$ | 96.9 |
| Diels-Alder Iminium ion <br> adduct hydrolysis 3 | n.d. | 62.3 |
| (Table 4.2) |  |  |

The theoretical data was found to be in reasonable agreement with the experimentally determined values. This experimental validation of the theoretical model was interesting as it provided the possibility of developing a predictive tool for catalyst activity.

### 4.3.9 Interpretation of Kinetic Data

By comparing the physical data for the steps of the catalytic cycle, we concluded that the Diels-Alder cycloaddition was the rate determining step of the catalytic cycle as it had a smaller rate constant than iminium ion formation. It can also be concluded that the DielsAlder cycloaddition had the lower activation energy of the two steps measured.

The physical parameter that was most interesting for the development of more active catalysts was the magnitude and consequence of the Arrhenius parameter $A$. The $A$ value contains qualitative information as to the nature of the transition state and is commonly
thought of as the number of collisions that take place per second, independent of the energy of the colliding molecules. This $A$ value is then multiplied with the Boltzmann term containing the activation energy and temperature. Therefore, the magnitude of rate constant $k$ at a constant T depends on $A$ and $E_{a}$.

$$
k=A e^{-\frac{E_{a}}{R T}}
$$

Iminium ion formation is a bimolecular reaction which requires two atoms to approach each other in the correct geometry for reaction. In this case it will be related to the Bürgi-Dunitz angle of $109^{\circ}$. The probability of this collision is relatively high and is reflected in the A value of $6.694 \times 10^{15} \mathrm{~s}^{-1}$ with a uncertainty of $\pm e^{3.17}$. The thermal Diels-Alder cycloaddition however, is a concerted process and therefore requires four atoms to collide in the correct geometry for reaction. The probability of this is far smaller as a consequence of the ordered transition state necessary for a pericyclic reaction which is clearly reflected in the magnitude of the A value of $4.14 \times 10^{4} \mathrm{~s}^{-1}$ with a uncertainty of $\pm e^{0.17}$.

It can be concluded that the Diels-Alder cycloaddition is the rate determining step due to the highly ordered concerted transition state that defines the reaction. The small magnitude of A is effectively constant for this pericyclic process and consistent with reported A values for uncatalysed Diels-Alder reactions. ${ }^{108}$ Manipulation of the reactive system to achieve a higher value of A would be extremely difficult. Therefore, in order to increase the magnitude of the rate constant $k_{D A}$ a lowering in the energy of the LUMO of the iminium ion should be targeted to decrease the magnitude of $\mathrm{E}_{\mathrm{a}}$ which, according to our findings will accelerate the overall reaction.

This conclusion can be used to explain the need for a $\beta$-EWG in active catalysts. The $\beta$-EWG further reduces the energy of the LUMO of the iminium ion thus making it more active. Explanation of the reactivity of catalysts based on the pyrrolidine scaffold is also possible. We demonstrated that pyrrolidine hydrochloride 69 forms iminium ions (for Xray data see Appendix) but is extremely sluggish in catalysing the Diels-Alder reaction ( $<5 \% 6 \mathrm{~h}$, Table 4.3 entry 1). Proline methyl ester hydrochloride 70 is a significantly

Chapter 4 $\qquad$ TJ K Gibbs- PhD Thesis 2008
more active catalyst containing a moderate EWG which is reflected in our catalytic observations ( $62 \%, 6 \mathrm{~h}$, entry 2). Activity is increased further when a strong $\beta$-EWG is present such as trifluoromethylpyrrolidine hydrochloride 112. HCl ( $93 \%, 6 \mathrm{~h}$ ).

### 4.3.10 Diels Alder Reaction with Cinnamaldehyde Derivatives

We had now hypothesised that the energy of the LUMO was responsible for overall activity. To allow us to test this for our system we wanted to examine a range of cinnamaldehyde derivatives ( $\mathbf{2 0} \mathbf{1 1 9 - 1 2 1}$ ) which would vary the electron density located in the LUMO of the dienophile and hence change the energy associated with it.

20

119

120

121

The aldehydes were submitted to the standard Diels-Alder reaction with cyclopentadiene and catalyst 7 in MeOH for 6 h (Scheme 4.9).

(Scheme 4.9)

| Entry | Aldehyde $^{\mathrm{a}}$ | ${\text { Conversion } \%^{\mathrm{a}}}^{\text {endo/exo }}$ |  |
| :---: | :---: | :---: | :---: |
| 1 | 20 | 86 | $57: 43$ |
| 2 | 119 | 97 | $58: 42$ |
| 3 | 120 | 55 | $60: 40$ |
| 4 | 121 | 0 | n.d |

(a) Reactions were carried out at $25^{\circ} \mathrm{C}$ for 6 hours with $10 \mathrm{~mol} \%$ catalyst in methanol.(b) Conversion determined by ${ }^{1} \mathrm{H}$ NMR of crude reaction mixture.

Electron deficient aldehyde 119 (Table 4.3 entry 2) preformed best with $97 \%$ conversion followed by cinnamaldehyde 20 (entry 1) at $86 \%$ conversion. Electron rich aldehyde $\mathbf{1 2 1}$ (entry 3) gave 55\% conversion while aldehyde $\mathbf{1 2 0}$ (entry 4) failed to react.

The usefulness of this study is limited, as the order of reactivity could have been predicted beforehand from frontier orbital arguments ${ }^{109}$ and the electronics of the aldehyde will also effect iminium ion formation as there is a distinct difference in the electrophilicity of the respective carbonyl groups. However, what is significant is that with a strong electron donating group on the aldehyde $\mathbf{1 2 0}$ no reaction occured. This electron donating effect should also make the carbonyl less electrophilic and should decrease the rate of iminium ion formation. However, we were able to isolate compound 128 at ambient temperature from methanol (confirmed by HRMS). We were also able to crystallise iminium ion $\mathbf{1 2 9}$ derived from catalyst 112. Catalyst $\mathbf{1 1 2}$ is of similar activity to catalyst 7 suggesting that iminium ion formation for catalyst with similar activity is not a significant step in the overall catalytic cycle for this substrate.

(Figure 4.13)
$\qquad$

### 4.3 Conclusions

Isolation of the key iminium ion $\mathbf{1 2 2}$ allowed us to obtain kinetic data of the components of the catalytic cycle. From this data we can concluded that the Diels-Alder cycloaddition was the RDS of the catalytic cycle for our model system. The magnitude of the rate constant $\mathrm{k}_{D A}$ is governed by the associated $A$ value. The small magnitude of the $A$ value is a consequence of the highly ordered transition state of the concerted Diels-Alder reaction. Iminium ion formation was found to have an activation energy of $100 \mathrm{~kJ} \mathrm{~mol}^{-1}$ consistent with the theoretically calculated value. The hydrolysis of the Diels-Alder iminium adducts was found to be extremely rapid and not observable on the ${ }^{1} \mathrm{H}$ NMR timescale.

The conclusions drawn allowed us to rationalise the role of the $\beta$-EWG acting to lower the energy of the LUMO of the reactive iminium ion. The results could now be incorporated in the design of novel catalysts suggesting that increased electron withdrawing ability of the $\beta$-EWG should afford increased activity.

Chapter 5: Design and Synthesis of More Active Catalysts for the Organocatalysed Diels-Alder Reaction

### 5.1 The Aim of the Research

The aim of these synthetic investigations was to prepare a more active variant of MacMillans imidazolidinone catalyst 7 by incorporating an additional $\beta$-EWG. Upon synthesis, catalytic testing would be conducted to establish whether the information gained from our mechanistic studies could be successfully applied to increase catalyst activity.

### 5.2 Introduction

MacMillans imidazolidinone catalyst 7 has been extremely successful and efficiently catalyses a wide range of transformations. ${ }^{110}$ Furthermore, other catalysts developed within MacMillans group based around a similar architecture catalyse an even wider number of transformations. However, widespread industrial use of the methodology has not occurred principally due to the high catalyst loadings that are necessary which can prove unworkable in large-scale synthesis. Increasing the reactivity of these catalysts while maintaining the asymmetric induction reported would therefore be more attractive to industry and academia alike.

7

Having identified the Diels-Alder cycloaddition as the RDS of the catalytic cycle and acknowledged the physical reasons for the magnitude of the rate constant, we targeted a lowering in the energy of the LUMO of the iminium ion to increase the rate of the cycloaddition and therefore the overall catalytic cycle. In order to achieve this LUMO energy lowering effect we rationalised that inclusion of an additional $\beta$-EWG in the scaffold of catalyst 7 could lead to increased reactivity.

The proposed, and widely accepted argument to explain the asymmetry observed in the asymmetric Diels-Alder reaction catalysed by 7 is that subtle differences in the steric requirements for the $E$-isomer 132 and $Z$-isomer 133 of the iminium ion lead to the exclusive formation of the $E$-isomer. This can be visualised when the two isomers of the iminium ion are drawn with the benzyl group away form the $\pi$-system (as the evidence from our solid-state studies suggest might be the true conformation (Chapter 4). The iminium ion in the $Z$-conformation (133) has an additional steric interaction with the geminal dimethyl group of the catalyst. This steric interaction is absent in the E-conformation(132) and therefore it is favoured energetically (Figure 5.1).

E-Isomer 132

Z-Isomer 133
(Figure 5.1)

To ensure that this mode of asymmetry is maintained within our modified catalysts, it was imperative that we maintained this structural feature by designing catalysts with similar spatial coordinates.

### 5.3 Results and Discussion

### 5.3.1 Computationally Aided Catalyst Design

Initially, based on experience within the group, we selected a number of catalyst targets 134-137 that we believed would demonstrate increased activity (Figure 5.2).

134

135

136

137
(Figure 5.2)

Catalyst $\mathbf{1 3 4}$ and $\mathbf{1 3 5}$ contained the trifluoromethyl functionality as the $\beta$-EWG which we had identified as a good candidate to increase activity. Compounds 136 and 137 were identified as good candidates form SAR studies prior to the mechanistic investigation.

Having hypothesised that it was the LUMO energy lowering ability of a catalyst that was important for activity (provided the active nitrogen was sufficiently nucleophilic) we saw the opportunity to use basic computational modelling to establish whether there was a correlation between the energy of the LUMO and catalyst activity.

To achieve this we conducted Hartree-Fock (HF) geometry optimisations on the $E$-isomers of the iminium ions of the catalysts $134-137$ with acrolein and then subsequently introduced a phenyl group into the plane of the iminium to represent cinamaldehyde. We then re-optimised the geometry using HF and it was from this final optimisation that we then extracted the energy of the LUMO corresponding to the $\pi$-system of the iminium ion. The values obtained could not be treated as absolute values. Instead it was the relative values that allowed direct comparison between activity determined experimentally and the calculated values of the LUMO energy. This form of calculation was also performed on iminium ion 122 and a pictorial representation of the results obtained in these investigations is shown in (Figure 5.2).

(Figure 5.2)

The results of these calculations had to be treated with some caution as it was known that HF is an inaccurate method for delocalised systems, such as the $\pi$-system of the iminium ion. This is due to the approximations made about electron correlation in the construction of the HF theory. These inaccuracies should be largely consistent for molecule of a similar structural class. HF does, however, have the advantage that it allows rapid and simple calculation of the LUMO energy which allows many catalysts to be screened in a short period of time. Higher levels of theory might provide more accurate calculations but the time and financial costs involved would be far greater.

A correlation was found between activity and LUMO energy for a catalyst of similar structural class. The correlation did not extend between structural classes. The example that illustrates this best is comparison of pyrrolidine hydrochloride 69 and trifluoromethyl pyrrolidine hydrochloride $\mathbf{1 1 2} . \mathrm{HCl}$. Pyrrolidine hydrochloride $\mathbf{6 9}$ is a poor catalyst ( $<5 \%$, 6 h ) although we have good evidence it formed iminium ions (X-ray). This suggested that the iminium ion was not sufficiently activated to facilitate a rapid Diels-Alder cycloaddition reaction. The pyrrolidine derived iminium ion had a calculated LUMO energy of -2.50 eV (Table 5.1, entry 1) Trifluoromethyl pyrrolidine derived iminium ion 122 however, was a considerably more active catalyst $(93 \%, 6 \mathrm{~h})$ and contained a $\beta$-EWG that lowered the energy of the LUMO. The calculated value obtained for $\mathbf{1 2 2}$ is -2.78 eV (Table 5.1, entry 2 ).
$\qquad$

| Entry | Catalyst | Structure | Yield \% | LUMO energy eV |
| :---: | :---: | :---: | :---: | :---: |
| 1 | 69 |  | <5\% | -2.50 |
| 2 | 112 |  | 93\% | -2.78 |
| 3 | 7 |  | 80\% | -2.72 |
| 4 | 137 |  | n.d. | -2.72 |
| 5 | 135 |  <br> (Table 5.1) | n.d. | -3.24 |

Knowing that the simplistic model that we had developed had some credibility we calculated the LUMO energy of the iminium ions of our proposed catalysts $\mathbf{1 3 7}$ and $\mathbf{1 3 5}$ which were -2.72 and -3.24 eV , respectively. The value obtained for the LUMO energy of the iminium ion of catalyst 135 was extremely interesting as, according to our hypothesis, it should be extremely active. We therefore devoted considerable attention to its preparation.

### 5.3.2 Catalyst Synthesis

Our initial attempt to synthesise the compounds 134-137 was analogous to the method described by MacMillan to prepare catalyst 7. ${ }^{111}$ The procedure involved reacting the precursor 138 and the corresponding carbonyl compound in methanol at reflux for 16 h with $10 \mathrm{~mol} \%$ p-TSA as the catalyst.

The reaction of trifluoroacetone 139 with 138 led to the imine 140 . To encourage ring closure further attempts were conducted at higher temperatures but this led to occurrence of side reactions and decomposition.

(Scheme 5.1)

The reaction of hexafluororacetone trihydrate 141 with $\mathbf{1 3 8}$ also proved unsuccessful with the initial mass of starting material recovered. This observation suggested that the hexafluoroacetone trihydrate was a poor electrophile. We therefore consulted the literature and found examples where the hexafluoroacetone was first dehydrated and bubbled through a reaction solution as a gas facilitating rapid and efficient condensation reactions. ${ }^{112}$

(Scheme 5.2)

Initially, we bubbled gaseous hexafluoroacaetone through methanol at room temperature containing 138 and $p$-TSA but recovered only starting materials upon work up. Following literature precedent we selected DMSO as a solvent for the reaction as it had been successfully utilised in similar reactions. ${ }^{113}$ Attempts at room temperature yielded only starting materials. Conscious that temperature was important for successful reaction we repeated the reaction in DMSO at the elevated temperature of $80^{\circ} \mathrm{C}$. In the analysis of the resulting mixture we observed a molecular ion at the correct mass for the imine $\mathbf{1 4 2}$ or the desired catalyst $\mathbf{1 3 5}$, however, the ${ }^{1} \mathrm{H}$ NMR clearly indicated that the isolated spots were not pure and further purification proved unsuccessful. Time restrictions ended our pursuit of this catalyst.

138

143

16hrs

136
(Scheme 5.3)

The reaction of ethyl pyruvate $\mathbf{1 4 3}$ and $\mathbf{1 3 8}$ lead to a complex mixture of products from which no compound resembling 136 could be isolated. It was difficult to ascertain the fate of the starting materials. Further failed attempts, combined with the work previously conducted by Jones ${ }^{99}$ led us to abandon 136 as a target.

The reaction of diethyl oxomalonate 144 with $\mathbf{1 3 8}$ led to similar results (Scheme 5.4).

138

### 5.3.3 Catalyst Redesign

Having failed in successfully synthesising the catalysts $\mathbf{1 3 4}, \mathbf{1 3 5}, \mathbf{1 3 6}$, and 137 we set about attempting to introduce an alternative EWG into the MacMillan scaffold in an attempt to obtain proof of concept. This would allow us to establish if such modified catalysts would have greater activity. If proof of concept was obtained then significant synthetic effort would be justified in pursuit of our initial targets.

Analysing the catalysts reported by MacMillan we saw the opportunity to modify catalyst 145 by introducing benzaldehyde derivatives containing stronger EWGs (catalysts 146 and 147). We also believed that the additional EWG introduced in catalyst 148 would provide a rate enhancement (Figure 5.3).

145

146

147

148
(Figure 5.3)

Mindful of the difficulties encountered with the synthesis of these types of compound we also selected other EWGs to hopefully increase the likelihood of a successful synthesis (Figure 5.4).

149

150
(Figure 5.4)

The attempts at the synthesis of $\mathbf{1 4 8}$ failed, more than likely due to the crowded nature of the ketone. The synthesis of $\mathbf{1 4 7}$ using the conditions of MacMillan led to a complex mixture of compounds from which the product could not be identified.

Reacting p-nitrobenzaldeyde 151 with 138 at $80^{\circ} \mathrm{C}$ in MeOH yielded the corresponding imine 152. To assist in the cyclisation of the amide onto the imine we added HCl in ether as a strong acid to form the corresponding iminium ion 153 (Scheme 5.5). This strategy proved unsuccessful, as the only compounds observed were the imine 152 and the initial starting aldehyde 151.

(Scheme 5.5)
$\qquad$

Therefore, we attempted to form an iminium ion using protecting group strategies. We prepared the Boc 154, Cbz 155 and Bn 156 protected MacMillan precursors (Figure 5.5). Reaction of 154 and $\mathbf{1 5 5}$ with a variety of aldehydes led to no reaction in MeOH at $80^{\circ} \mathrm{C}$ and at elevated temperatures. The most plausible explanation for this is that the reduction in nucleophilicity of the protected nitrogen prevented formation of the iminium ion in both cases.

154

155

156
(Figure 5.5)

The benzyl protected catalyst $\mathbf{1 5 6}$ however, was still nucleophilic and on reaction with p-nitrobenzaldehyde 151 and glyoxylic acid 255 led to protected catalysts 157 (15\%) and 158 (17\%) respectively.

157

158
(Figure 5.6)

To convert 157 to 146 we performed a reduction using $10 \% \mathrm{Pd} / \mathrm{C}$ under an atmosphere of $\mathrm{H}_{2}$ (Scheme 5.6). The benzyl protecting group was removed but we also reduced the nitro group to the aniline to give compound $\mathbf{1 5 9}$ (as might have been expected) thus replacing our desired EWG with and an electron donating group.

(Scheme 5.6)

To prepare catalyst 149 (Figure 5.4) we successfully attempted to deprotect $\mathbf{1 5 8}$ with $\mathrm{Pd} / \mathrm{C}$ and $\mathrm{H}_{2}$ indicating that the deprotection step was feasible. However, we sought to form the methyl ester before deprotection. To achieve this we used concentrated $\mathrm{H}_{2} \mathrm{SO}_{4}$ in methanol as a catalyst which gave a complex mixture of products. Subsequently, we used diazomethane to form the ester which appeared to be good method. Despite our efforts catalyst 149 was not isolated although it is our belief that another attempt using diazomethane to form the ester followed by deprotection would yield the catalyst. Regrettably, time restraints and more encouraging results meant that a final attempt was not conducted.

We also reacted the benzyl protected amine 156 with trifluoroacetone, ethyl glyoxylate, ethyl pyruvate, dibromoacetic acid, chloral, pentafluorobezaldehyde, benzophenone and hexafluoroactetone under MacMillans conditions all without any indication of the desired products.

Having succeeded in synthesising and isolating the imine precursor $\mathbf{1 5 2}$ we made a final attempt at the preparation of catalyst $\mathbf{1 4 6}$ by refluxing the starting materials in DMSO for 1 h and then reacted at $120^{\circ} \mathrm{C}$ overnight which resulted in a small amount of desired catalyst 146 in $6 \%$ yield amidst numerous products.

(Scheme 5.7)

The result of this experiment indicated to us that the reaction required large amounts of energy in order to proceed. This prompted us to use microwave technology in order to deliver sufficient energy to the substrates. Initial success affording cleaner transformations using DMSO prompted us to begin to optimise a microwave procedure.

| Entry | Solvent | ${\text { Temperature }{ }^{\circ} \mathrm{C}}^{\text {Time (mins) }}$ | Yield of 146 |  |
| :---: | :---: | :---: | :---: | :---: |
| 1 | MeOH | 100 | 30 | trace |
| 2 | MeOH | 120 | 30 | trace |
| 3 | DMSO | 120 | 30 | $12 \%$ |
| 4 | DMSO | 120 | 90 | decomp |
| 5 | DMSO | 180 | 30 | decomp |
| 6 | DMF | 120 | 30 | $25 \%$ |
|  |  | (Table 5.2) |  |  |

Our brief optimisation indicated that MeOH was a poor solvent. The optimal temperature was found to be $120^{\circ} \mathrm{C}$ as higher temperatures gave greater quantities of side products. DMF emerged as the solvent of choice affording a clean reaction mixture with only product, starting materials and imine present by ${ }^{1} \mathrm{H}$ NMR. Further optimisation was not conducted in the interest of time.

### 5.3.4 Catalyst Performance

Having synthesised catalyst $\mathbf{1 4 6}$ as a single diastereoisomer, we prepared the HCl salt and examined it in the standard Diels-Alder reaction between cinnamaldehyde and cyclopentadiene with a range of catalyst loadings.

| Entry | Solvent | Catalyst loading $(\mathrm{mol} \%)^{\mathrm{a}}$ | Time (h) | Conversion \% ${ }^{\text {b }}$ | endo:exo ${ }^{\text {c }}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | MeOH | 10 | 6 | 99 | 65:35 |
| 2 | MeOH | 10 | 3 | 99 | 65:35 |
| 3 | MeOH | 5 | 3 | 82 | 65:35 |
| 4 | MeOH | 2.5 | 3 | 56 | 65:35 |
| 5 | MeOH | 1 | 3 | 23 | 67:33 |
| 6 | $\begin{gathered} \mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O} \\ 19: 1 \end{gathered}$ | 10 | 3 | 78 | 68:32 |
| (a) Catal (b) Conv (c) exo:e | st 146 used as | $\mathrm{HCl} \mathrm{salt} \mathrm{at} 25^{\circ} \mathrm{C}$. by ${ }^{1} \mathrm{H}$ NMR of crude rea ed by ${ }^{1} \mathrm{H}$ NMR of crude | ion mixture. eaction mixtu |  |  |

MeOH proved to accelerate the reaction compared to $\mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O}$. It is also noteworthy that the endolexo ratio observed for our catalysts was $2: 1$ whereas it was $1: 1$ for MacMillans original catalyst 7. The conversion of $82 \%$ after 3 hours at $5 \mathrm{~mol} \%$ loading is unprecedented and demonstrates superior activity to MacMillan catalyst 7 ( $99 \%$, $24 \mathrm{~h}, 5$ $\mathrm{mol} \%$ ). This result delighted us as we had only introduced a relatively weak EWG into the MacMillan scaffold. This result provided considerable encouragement form which to pursue some of the synthetically more challenging catalysts.

### 5.3.5 Testing the Predictive Model

The experiments demonstrated that catalyst 146 ( $82 \%, 3 \mathrm{~h}, 5 \mathrm{~mol} \%$ ) was indeed significantly more active than MacMillan's imidazolidinone 7 ( $89 \%$, $6 \mathrm{~h}, 10 \mathrm{~mol} \%$ ) validating our design concept. The level of activity present at $5 \mathrm{~mol} \%$ catalyst loading $(82 \%, 3 \mathrm{~h})$ was sufficient to be a practical alternative to using higher loadings.

Synthesising an active catalyst gave us a chance to test our simplistic computational LUMO energy model. Pleasingly, the energy of the LUMO corresponding to the $\pi^{*}$ orbital of the iminium ion of $\mathbf{1 4 6}$ was -2.86 eV compared to that of the original catalyst $\mathbf{7}$ -2.72 eV . This is consistent with our hypothesis that the lower the energy level of the LUMO energy the more active the catalyst. The LUMO energy value obtained for the iminium ion of catalyst 146 was still significantly higher than that of proposed catalyst 135, further highlighting 135 as a desirable catalyst to synthesise.

### 5.3.6 Asymmetric Induction

To establish the relative conformation of the catalyst 146 we used NOESY NMR. Analysis of the spectrum displayed an enhancement between $\mathrm{H}_{\mathrm{a}}$ of the ring junction and $\mathrm{H}_{\mathrm{b}}$ in the ortho-position of the nitrophenyl ring indicating that they are close in space (Figure 5.7). This observation is most consistent with that of the catalyst with the trans-conformation with respect to the benzyl and nitro phenyl groups.

To determine whether catalyst $\mathbf{1 4 6}$ had led to any asymmetric induction in the DielsAlder cycloaddition reaction, we formed the corresponding 2,4-DNP derivatives ${ }^{114}$ (160) (Scheme 5.8). Subsequent analysis of the derivatives by chiral phase HPLC was conducted in accordance to the methods developed by Cavill. ${ }^{115}$

$\qquad$

We found that the enantiomeric excess present was an excellent $87 \%$ for the $2 R, 3 R$ endo-isomer $\mathbf{2 5 - R}$ and a disappointing $26 \%$ for the $2 R, 3 R$ exo-isomer $\mathbf{2 4 - R}$.

(Figure 5.8 )

Knowing the relative trans-stereochemistry of the catalyst allowed us to develop a tentative transition state model to assist in explaining the experimental observations. Our first assumption was that exchanging the geminal dimethyl group in catalyst 7 for a nitrophenyl and a hydrogen in catalyst 146 would lead to loss of control in iminium ion geometry.

(Figure 5.9 )

Provided that both $E$ and the $Z$-isomers of the iminium ion were present in solution there were eight transition-states that could lead to a product (Figure 5.10). The Si and Re labels refer to the face of the dienophile that is approached by the diene in order to provide the Diels-Alder cycloaddition products $\mathbf{2 4 - S} / \mathbf{2 5}-S$ and $\mathbf{2 4 - R} / \mathbf{2 5 - R}$ respectively.
$\qquad$

163

$Z$-isomer-Re-endo 167

164

$Z$-isomer-Re-exo 168
(Figure 5.10)

Without evidence to suggest the position of the benzyl arm in the reactive conformation of the iminium ion, it is difficult to discuss the mode of stereo-induction with any accuracy. The e.e, observed for the endo Diels-Alder product can be explained: in the Si-endo transition-states 161 and 166 the approach of the diene is hindered. This hindrance is not present in the Re-endo transition-states 164 and 167 promoting reaction at the $R e$-face of the iminium ion for endo-approach of the diene. Therefore the $\mathbf{2 5 - R}$ Diels-Alder product is favoured consistent with our observation.

The selectivity observed for the exo-Diels-Alder product was much smaller and more difficult to rationalise. Transition-states 165 and 162 should be the most energetically favoured as approach of the diene is less hindered compared to $\mathbf{1 6 3}$ and 168. The observation of this slight stereo enhancement indicates there must be a small energy difference between 165 and 162 compared to 163 and 168. The origin of this energy difference is difficult to rationalise using basic modelling due to the large number of variables. The use of computational transition state modelling could provide a more detailed analysis that might explain the observed sense of asymmetric induction for the exo product 24-R.

Interested by the levels of asymmetric induction observed with catalyst 146 we considered whether ( $R$ )-2-(trifluoromethyl)pyrrolidine 169 would yield enatioenriched products (Figure 5.11). We obtained commercially available 169 and prepared the corresponding HCl salt prior to utilising it as a catalyst in the reaction of cinnamaldehyde and cyclopentadiene at $25^{\circ} \mathrm{C}$ in methanol.

(Figure 5.11)

The Diels-Alder product was purified and a portion converted to the $2,4 \mathrm{DNP}$ derivative 160 for analysis by chiral phase HPLC. We found a pleasing $84 \%$ e.e. for the minor endo $\mathbf{2 5}-\boldsymbol{R}$ isomer and $4 \%$ e.e. for the major exo $\mathbf{2 4 - R}$ product. Construction of a simple transition state model provides an explanation of the enantioinduction observed. Previous X-ray and spectroscopic data indicated that only the $E$-isomer was present in solution, therefore only four transition-states need be considered.

170

171

172

173
(Figure 5.12)

The steric differentiation for the transitions states with exo approach of the diene to the Si and the $R e$ face 171 and $\mathbf{1 7 2}$ is minimal. Transition states $\mathbf{1 7 1}$ and $\mathbf{1 7 2}$ should therefore be of similar energy, consequently resulting in a low e.e. There is a larger steric differentiation between the $S i$ and $R e$ faces with endo attack of the diene. In the Si-endo transition state $\mathbf{1 7 0}$ the approach of the diene is hindered by the trifluoromethyl group. This hindrance is not present in the Re-endo transition state 173. The additional steric hindrance in 170 raises its energy and therefore disfavours formation of the endo $2 S, 3 S$ Diels-Alder product leading to the favoured endo $2 R, 3 R$ product 25-R.

### 5.4 Conclusions

We have demonstrated that the inclusion of an additional $\beta$-EWG within the scaffold of the MacMillan imidazolidinone will increase catalyst activity consistent with our hypothesis. We failed to synthesise catalysts 134, 135, 136, or 137 which are architecturally similar to MacMillan's imidazolidinone 7. However, the catalyst $\mathbf{1 4 6}$ that we synthesised afforded good $87 \%$ e.e. for the 25-R Diels-Alder adduct. Unfortunately, the e.e. for the $\mathbf{2 4 - R}$ isomer, which was the major product, was found to be $26 \%$. With the experimental observations obtained we were able to construct a transition state model to explain the observed sense of induction. Straightforward arguments could be invoked to explain the e.e, of the endo isomer $\mathbf{2 5 - R}$ whereas the sense of asymmetric induction for the exo isomer 24-R was more difficult to explain.

The calculated energy of the reactive LUMO of 146 is significantly lower than the calculated value for the corresponding LUMO energy of the iminium ion derived from MacMillan's catalyst 7. This provides further evidence that lowering in the LUMO energy will increase activity provided a nucleophilic amine is present in the scaffold. This evidence also provides credibility to our simplistic model and as a consequence can be used with more confidence.

To achieve a highly active asymmetric catalyst compounds $134,135,136$ and 137 should be targeted. The use of microwave technology could prove crucial in the synthesis of these molecules as it appears that large amounts of energy are needed to facilitate efficient cyclodehydration.

# Chapter 6: Development of a Novel Catalytic Architecture for the Secondary Amine Catalysed Diels-Alder Reaction of Enones 

### 6.1 The Aims of the Research

The aim of this study was to develop a piperazindione scaffold as a catalytic architecture, suitable upon modification, to facilitate the asymmetric organocatalysed Diels-Alder reactions of $\alpha, \beta$-unsaturated ketones and aldehydes. We sought to synthesise a series of simple catalysts based around the piperazindione structure to obtain proof of concept by demonstrating their ability to catalyse Diels-Alder reactions involving aldehydes and ketones. Once achieved, synthesis of more challenging chiral variants would begin.

### 6.2 Introduction

To date, there have been a number of reports of organocatalysed Diels-Alder reaction with $\alpha, \beta$-unsaturated aldehydes with excellent yields and selectivity. ${ }^{116}$ However, this success has not been mirrored with more challenging $\alpha, \beta$-unsaturated ketone substrates of which there is only one report. ${ }^{117}$

The group of MacMillan were the pioneers in this challenging area. Their initial investigations indicated that catalyst 7, which had been successful for the asymmetric Diels-Alder reaction of $\alpha, \beta$-unsaturated aldehydes, was not effective with $\alpha, \beta$ unsaturated ketone substrates. Further investigations highlighted catalyst 9 with $\mathrm{HClO}_{4}$ as the co-acid was the optimal catalyst-co-acid combination for the asymmetric Diels-Alder reactions of $\alpha, \beta$-unsaturated ketones with cyclopentadiene (Table 6.1).
$\qquad$

(Scheme 6.1)

| Entry | Catalyst | $R^{1}$ | $R^{2}\left(R^{3}\right)$ | Time (h) | \% Yield | exo:endo | e.e. \% |

| 5 | 9 | Bn | $5-\mathrm{Me}-\mathrm{Furyl}(\mathrm{H})$ | 22 | 89 | $25: 1$ | 90 |

(Table 6.1)
It is clear from the results (Table 6.1) that the mode of asymmetric induction for reactions involving ketone substrates is different from that of aldehydes. The catalysts that provided the highest levels of enantioselectivity were 145 and 9 which both contain two sterically shielding groups cis-across the catalyst scaffold.

To explain the sense of asymmetric induction observed, MacMillan proposed a model which was supported by MM3 calculations. The structures obtained from these calculations are shown below (Figure 6.1).

(Figure 6.1)

Importantly, the model provided an explanation as to why methyl ketones provided poor enantioselectivities. The model stated that both the cis and trans iminium ions $\mathbf{1 7 9}$ and 178 were accessible, but the cis-iminium ion 179 was favoured energetically. With methyl ketone substrates one face of the $\mathrm{C}=\mathrm{C}$ bond was exposed for the cis and trans iminium ions $\mathbf{1 7 9}$ and $\mathbf{1 7 8}$ respectively. For the cis-iminium ion 179 it is the Si -face and for the trans iminium $\mathbf{1 7 8}$ the $R e$-face. Therefore low levels of asymmetric induction are observed. With ethyl ketone substrates the cis and trans-iminium ions $\mathbf{1 7 9}$ and $\mathbf{1 7 8}$ are also accessible. Crucially however, both faces of the trans-iminium ion $\mathbf{1 7 8}$ are blocked. The Si-face of the iminium ion 178 is blocked by the bulky furfural group and the $R e$-face by the terminal methyl group of the ethyl ketone substrate (Figure 6.1). The Si-face of cis-iminium ion 179 was exposed (analogous the methyl ketone substrates) and therefore reaction at this face predominates leading to the observed sense of asymmetric induction.

Further evidence to support the proposed mode of induction was sought through application of catalyst 9 with a series of cyclic $\alpha, \beta$-unsaturated ketones $\mathbf{1 8 0}$ (Table 6.2).

19

(Scheme 6.2)

| Entry | n | Time (h) | \% Yield | exo:endo | e.e. \% |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 0 | 12 | 81 | $15: 1$ | 48 |
| 2 | 1 | 17 | 81 | $12: 1$ | 63 |
| 3 | 2 | 28 | 85 | $18: 1$ | 90 |
| 4 | 3 | 72 | 83 | $6: 1$ | 91 |
| 5 | 10 | 72 | 88 | $5: 1$ | 93 |

The observed increase in enantioselectivity with increasing ring size (Table 6.2 entries 4 and 5) was consistent with the proposed model. The large ring cyclic dieneophiles ( $\mathrm{n}=3$, 10 , entries 4 and 5) possess a higher degree of rotational freedom about the $\mathrm{N}=\mathrm{C}$-alkyl bond of the iminium ion and therefore behave in a similar manner to the ethyl ketones with good $R e$-face coverage. However, dieneophiles with the smaller rings ( $\mathrm{n}=0,1$, entries 1 and 2) result in moderate enantioselectivities as a consequence of the restricted rotational freedom around the $\mathrm{N}=\mathrm{C}$-alkyl bond preventing effective coverage of the $R e$ face. The substrate specificity was therefore a consequence of the catalytic architecture of 9. No conjugate additions to $\alpha, \beta$-unsaturated ketones using the imidazolidinone architecture have been described to date. These observations revealed the opportunity to develop a universal catalyst that could tolerate both $\alpha, \beta$-unsaturated aldehydes and ketones as substrates.

### 6.2.1 Catalyst Design

Having rationalised that an active asymmetric catalyst for Diels-Alder reaction with $\alpha, \beta$-unsaturated ketones required the following elements: a nucleophilic nitrogen, a $\beta$ EWG and a chiral scaffold that could selectively hinder attack at one diasterotopic face of the iminium ion we proposed catalyst 185 as a novel candidate.

185

Piperidine is known to have a higher nucleophilicity than acyclic secondary amines. The piperazindione $\mathbf{1 8 5}$ should have a relatively flat geometry caused by the geometrically planar amides. This flattening of the ring should further expose the lone pair of the nitrogen and thus further increase the nucleophilicity. The scaffold of $\mathbf{1 8 5}$ also contains two $\beta$-EWG's which could facilitate a further increase in activity. Finally, the fact that the catalyst was $\mathrm{C}_{2}$ symmetric dictates that independent of the geometry of the iminium ion, the same diastereotopic face should be shielded leading subsequent asymmetric reactions. For example, the iminium ions derived from 185 and cyclohexanone are identical and hence the stereochemical course of subsquent reactions would be the same (Figure 6.2).

188

188
(Figure 6.2)

### 6.3 Results and Discussion

### 6.3.1 Preparation of Model Catalysts

Aware that synthesis of catalyst $\mathbf{1 8 5}$ may not be straightforward we set about synthesising a range of catalysts based around the piperazindione scaffold that would be synthetically more accessible to allow us to asses the feasibility of catalysts based around this scaffold.

189

190

191

192

193
(Figure 6.3)

Piperazin-2-one 189 was obtained commercially. Compounds 190 and 191 were synthesised according to the procedure of Mancilla by reaction of glycine ethyl ester hydrochloride 186 and phenylalanine ethyl ester hydrochloride 187 respectively with 2 bromoacetamide 194 (Scheme 6.3). ${ }^{118}$

(Scheme 6.3)

Compounds 192 and 193 were synthesised in an analogous manner by reacting $\alpha$-bromoester 195 with glycinamide 196 or phenylalaninamide 138 (Scheme 6.4).
$\qquad$

(Scheme 6.4)

Compound 193 was isolated in a respectable $78 \%$ yield while catalyst 192 was isolated in $29 \%$ along with $23 \%$ of the overalkylated byproduct 197. Attempts to improve the yield using toluene as the solvent failed to provide any of catalyst 192 while a reductive amination protocol utilising ethyl glyoxylate also proved unsuccessful. Despite the low yield, sufficient quantities of $\mathbf{1 9 2}$ could be obtained using this method to pursue our studies.

### 6.3.2 Piperazindiones as Catalysts for Diels-Alder Reaction with $\alpha, \beta$-aldehydes

Having obtained the catalysts we set about examining their activity with our standard Diels-Alder cycloaddition. Catalysts 189, 190-193 were converted to their hydrochloride salts by adding the free amines to 5 equivalents of HCl in ether. The catalysts were reacted at $10 \mathrm{~mol} \%$ catalyst loading with $(E)$-cinnamaldehyde 20 and cyclopentadiene 19 in MeOH and $\mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O}$ (19:1) as the solvents to gauge catalyst activity (Table 6.3).

(i) Catalyst ( $10 \mathrm{~mol} \%$ ), solvent, $25^{\circ} \mathrm{C}$. (ii) TFA, $\mathrm{CHCl}_{3}, \mathrm{H}_{2} \mathrm{O}$
(Scheme 6.5)
$\qquad$

| Entry | Catalyst ${ }^{\text {a }}$ | Time (h) | Solvent | Conversion \% ${ }^{\text {b }}$ |
| :---: | :---: | :---: | :---: | :---: |
| 1 | 191. HCl | 6 | MeOH | 38 |
| 2 | 191. HCl | 6 | $\begin{gathered} \mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O} \\ 19: 11 \end{gathered}$ | 18 |
| 3 | $192 . \mathrm{HCl}$ | 6 | MeOH | 15 |
| 4 | 192. HCl | 24 | MeOH | 32 |
| 5 | 192. HCl | 6 | $\begin{gathered} \mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O} \\ 19: 11 \end{gathered}$ | 41 |
| 6 | 192. HCl | 24 | $\begin{gathered} \mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O} \\ 19: 11 \end{gathered}$ | 54 |
| 7 | 192. HCl | 24 | $\begin{gathered} \mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O} \\ 19: 11 \end{gathered}$ | $69^{\text {c }}$ |
| 8 | 193.HCI | 6 | MeOH | 44 |
| 9 | 193.HCI | 6 | $\begin{gathered} \mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O} \\ 19: 11 \end{gathered}$ | 22 |
| 10 | $193 . \mathrm{HCl}$ | 24 | MeOH | 62 |

(a) catalyst used at $10 \mathrm{~mol} \%$ loading as the HCl salt in the stated solvent at $25{ }^{\circ} \mathrm{C}$ with 2.5 equivalents 19 (b) conversion determined by ${ }^{1} \mathrm{H}$ NMR of the crude reaction mixture (c) reaction conducted at $20 \mathrm{~mol} \%$ loading with 5 equivalents of 19.
(Table 6.3)

Catalyst $189 . \mathrm{HCl}$ and $190 . \mathrm{HCl}$ proved inactive for the transformation with no reaction occurring after 6 h . This somewhat surprising result may be explained by the limited solubility of these catalysts in the reaction medium. Catalyst $191 . \mathrm{HCl}$ displayed moderate activity ( $38 \%$, Table 6.3, entry 1) in MeOH and low activity in $\mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O}$ (19:1) ( $18 \%$, Table 6.3, entry 2). Catalysts $192 . \mathrm{HCl}$ and $193 . \mathrm{HCl}$ which both contain a methyl amide performed better. The optimal solvent for $192 . \mathrm{HCl}$ was $\mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O}$ (19:1) leading to modest conversion ( $54 \%$, Table 6.3, entry 6) while for catalyst 193. HCl the optimal solvent was $\mathrm{MeOH}(44 \%$, Table 6.3, entry 8).

Examining the literature it was evident that there was no single co-acid that was efficient with all catalysts or indeed in every transformation. Therefore, we tested catalyst 192 with a range of co-acids in the standard Diels-Alder reaction with $(E)$-cinnamaldehyde 20 and cyclopentadiene 19 conducted in $\mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O}$ (19:1) (Table 6.4).

| Entry $^{\text {a }}$ | Co-acid | Conversion\% ${ }^{\text {b }}$ |
| :---: | :---: | :---: |
| 1 | $\mathbf{H C l}$ | 41 |
| 2 | HCIO $_{4}$ | 22 |
| 3 | TFA | 33 |
| 4 | TCA | 25 |
| 5 | HPF $_{6}$ | 4 |
| 6 | MsOH | 50 |
| 7 | BzOH | 0 |

(a) catalyst used at $10 \mathrm{~mol} \%$ loading as stated salt in $\mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O}$ (19:1) for 6 h at $25^{\circ} \mathrm{C}$ with 2.5 equivalents 19 (b) conversion determined by ${ }^{1} \mathrm{H}$ NMR of the crude reaction mixtures
(Table 6.4)

The study found that HCl and MsOH were the optimal co-acids for the standard DielsAlder reaction (entry 1 and 0). Consistent with previous findings BzOH and $\mathrm{HPF}_{6}$ were poor co-acids for the reaction. ${ }^{119}$ TFA, TCA and $\mathrm{HClO}_{4}$ all provided moderate yields for the reaction (entries 2,3 and 4). Given the similar activities of MsOH and HCl as coacids, HCl was chosen as it allowed the convenient use of the preformed HCl salts of catalysts in the reactions.

### 6.3.3 X-Ray Study

A key feature in our design of catalyst 185 was the increased nucleophilicity of the nitrogen, facilitated by the flat geometry of the ring. To investigate the extent of this effect we attempted to form crystals of the iminium ions derived from the model catalyst 192 to allow further insight.

(Figure 6.4.)

We formed the iminium ion $\mathbf{1 2 5}$ by reaction of $\mathbf{1 9 2}$ with cinnamaldehyde 20 and $\mathrm{HPF}_{6}$ cleanly in $72 \%$ yield (Scheme 6.6). Crystals suitable for X-ray crystallography were obtained by evaporation from $\mathrm{CH}_{3} \mathrm{CN}$. The crystal structure confirmed our hypothesis that the piperazindione ring would have a high degree of planarity and hence an enhanced nucleophilicity (Figure 6.4).

### 6.3.4 Diels-Alder Reactions with $\alpha, \beta$-Unsaturated Ketones

Our initial aim was to develop a reaction that could be used as a benchmark to aid in the development of future catalysts for this class of transformation. We chose the literature reaction of cyclohexenone 198 and cyclopentadiene 19 to probe the reactivity of our catalysts (Scheme 6.7). ${ }^{120}$
$\qquad$

(Scheme 6.7)

Attempts using catalysts 112, 70, 7, and 91 all failed to provide any indication of product 181. The product 181 was isolated however, in $1.4 \%$ yield from the Brønsted acid catalysed reaction utilising $20 \mathrm{~mol} \% \mathrm{HCl}$ over a 4 day period.

112. HCl

70

7

91

We then examined the reaction of 4-hexen-3-one 175 with cyclopentadiene 19 utilising MacMillans catalyst $\mathbf{9 . H C l O}_{4}$. Performing this reaction and isolating the product allowed us to develop a method for the determination of the conversion of the reaction by analysis of the ${ }^{1} \mathrm{H}$ NMR of the crude reaction mixture. The NMR spectra of $\mathbf{1 7 5}$ (Figure 6.5) and $\mathbf{1 7 6}$ (Figure 6.0) display diagnostic peaks at 6.85 ppm for $\mathbf{1 7 5}$ and 5.83 ppm for $\mathbf{1 7 6}$ to allow for measurement of conversion.

(Figure 6.5)

(Figure 6.6)

We then submitted our piperazindione catalyst $192 . \mathrm{HCl}$ and $193 . \mathrm{HCl}$ to the reaction conditions developed by MacMillan to discover whether our catalysts were active with ketone dienophiles. To our delight we obtained conversions of 21 and $26 \%$ for the transformation with catalysts $192 . \mathrm{HCl}$ and $193 . \mathrm{HCl}$ respectively ( $20 \mathrm{~mol} \%, \mathrm{H}_{2} \mathrm{O}, 24 \mathrm{~h}$ )
clearly demonstrating the ability of piperazin-2,6-diones to catalyse the organocatalysed Diels-Alder reaction with ketone dienophiles.

### 6.3.5 Development of an Asymmetric Piperazin-2,6-dione

Knowing that the catalysts based around the piperazin-2,6-dione scaffold were active for the reaction of ketone dienophiles in the Diels-Alder reaction we set about synthesising catalyst 185 as a chiral variant. Our first attempt was to perform a reported Ugi reaction that had been utilised to construct similar compounds (Scheme 6.9). Ugi had reported a one-pot synthesis of related non symmetrical compounds, however, the diastereoselectivity of these reactions was not discussed within the paper. ${ }^{121}$

(Scheme 6.9)

The procedure involved formation of iminium ion 202 from reaction of phenylacetaldehyde 200 with $L$-phenylalanine 201. The iminium ion 202 can undergo attack from the isocyanide 203 followed by intramolecular attack of the carboxylic acid to form cyclic intermediate 204. Hydrolysis of the intermediate with methanol leads to the acyclic precursor $\mathbf{2 0 5}$ which upon cyclisation with loss of methanol gives compound 185, preferably with the desired trans-stereochemistry. Unfortunately, the reaction provided a complex mixture of compounds from which the desired product was not
isolated. This fact, coupled with the rancid stench of compound 203 led us to abandon this method as a route to 185 .

Our second approach was to modify the preparation that we had used to synthesise compounds 192 and 193. To begin the synthesis we prepared bromo-ester 208 from ketoester 206 and NBS via isolated intermediate 207 in $82 \%$ overall yield (Scheme 6.10). ${ }^{122}$

(Scheme 6.10)

The bromo-ester 208 was initially reacted with $\mathbf{1 3 8}$ in $\mathrm{CH}_{3} \mathrm{CN}$. This led to ethyl cinnamate 209 as the major isolated product via an elimination reaction (Scheme 6.11). The reaction yielded other unidentifiable spots by TLC whose spectroscopic data was not consistent with the desired product.

(Scheme 6.11)

The reaction was repeated in toluene which allowed isolation of a compound whose analytical data was consistent with that of the diasteriomeric uncyclised compound $\mathbf{2 1 0}$, determined from ${ }^{1} \mathrm{H}$, COSY and HSQC NMR spectra. However, full characterisation was not possible with the available data and without further purification. Time constraints ended our synthetic efforts at compound 185.

(Figure 6.7)

Future attempts at the preparation of catalyst $\mathbf{1 8 5}$ could use the work of MacMillan who has reported compound 211 as a catalyst for the Diels-Alder cycloaddition. ${ }^{123}$

(Figure 6.8)

Adaptation of this methodology should allow for the synthesis of $\mathbf{1 8 5}$ with the desired trans- stereochemistry (Scheme 6.12). Evaluation of 185 as an asymmetric catalyst for the Diels-Alder reaction of $\alpha, \beta$-unsaturated ketones and other iminium ion catalysed reactions could then be conducted.

212

(Scheme 6.12)

### 6.4 Conclusions

The work to date has demonstrated that catalysts based on the piperazin-2,6-dione scaffold as their HCl salts can be effectively deployed to accelerate the Diels-Alder reaction of $\alpha, \beta$-unsaturated aldehydes and ketones. We have developed a method for the rapid determination of catalyst activity based around conversions determined from the ${ }^{1} \mathrm{H}$ NMR spectrum of the crude reaction mixture. However, this method has yet to be fully validated. Structural studies on the iminium ion derived form catalyst 192 indicate that these cyclic catalysts have the desired flat geometry designed to increase the nucleophilicity of the active nitrogen. The synthesis of an asymmetric variant has to date proved elusive

Chapter 7: Investigations into an Organocatalytic Dynamic Resolution Procedure

### 7.1 The Aims of the Study

We sought to demonstrate the reversibility of an organocatalysed Michael addition reaction with a view to the development of an organocatalysed chiral dynamic resolution procedure.

### 7.2 Introduction

The notion of chiral dynamic resolution is an extremely attractive concept for organic synthesis. It allows for the installation of a racemic functionality early within a synthesis followed by chiral resolution in the final stages. With consideration of the complex and synthetically challenging compounds that are frequently targets in modern chemistry, development of such methods would provide a powerful alternative tool to aid the efficient synthesis of optically active compounds.

(Scheme 7.1)

In order to afford dynamic chiral resolution, an asymmetric reagent or catalyst is required. Catalytic dynamic resolution is of course the more attractive. The search for a chiral resolution procedure should then begin with a search for an asymmetric transformation facilitated by a catalyst which could be reversible under the reaction conditions. Examination of the literature suggested that the Michael addition reaction would be a good candidate.

The reversibility of the Michael addition reaction is well documented. ${ }^{124}$ There are examples of reversibility where cleavage of C-C, ${ }^{125} \mathrm{C}-\mathrm{N},{ }^{126} \mathrm{C}-\mathrm{O}^{127}$ and $\mathrm{C}-\mathrm{S}^{128}$ bonds have occurred in a retro-Michael fashion. An example of this is with the naturally occurring alkaloid myrtine 215 which readily undergoes epimerisation under acidic or basic conditions via intermediate 216 to yield a 1:1 mixture of myrtine 215 and
epimyrtine 217. ${ }^{129}$ The proposed mechanism of this epimerisation was a retro-Michael reaction followed by a non selective Michael addition.

(Scheme 7.2)

A further example of the facility of these processes is the enzyme catalysed dynamic resolution of oxazole 218 which is believed to undergo a retro-Michael reaction to give 219 followed by a selective Michael addition to give 220 and finally hydrolysis to give 221. ${ }^{130}$

(Scheme 7.3)

Having examined the literature we rationalised that this type of process could be achieved utilising asymmetric organocatalysed Michael additions. We therefore set about finding a procedure that we could adapt to investigate the possibilities of organocatalysed dynamic resolution.

Within the field of organocatalysis Ogilvie began to develop a chiral dynamic resolution for the asymmetric Diels-Alder reaction catalysed by hydrazide 21 (Scheme 7.4). ${ }^{131}$

(Scheme 7.4)

Within his report Ogilvie stated that the iminium ion catalysed Diels-Alder reaction was reversible. He also concluded that the forward Diels-Alder reaction was catalysed by the hydrazide 21 while the retro-Diels-Alder reaction is primarily catalysed by the TfOH coacid. Ogilvie demonstrated that on adding 21 to a racemic mixture of $\mathbf{2 4}$ and $\mathbf{2 5}$ under the standard reaction conditions for 48 h a small increase in the e.e. was observed. Despite his initial success Ogilvie did not fully exploit this observation to develop an efficient dynamic resolution procedure, primarily due to the sluggish kinetics encountered for the reversible process.

We sought to obtain a proof of concept for a dynamic resolution procedure with an organocatalysed Michael addition reaction by demonstrating the reversibility of another process. Once this was achieved we could tune the reaction conditions to obtain a practical dynamic resolution procedure.

Our attention was drawn to the work of Jørgensen who had described asymmetric organocatalytic C-C bond forming Michael additions of nitroalkanes, ${ }^{132} \beta$-keto esters, ${ }^{133}$ 1,3 -dicarbonyls ${ }^{134}$ and $\beta$-keto-sulphones ${ }^{135}$ to $\alpha, \beta$-unsaturated carbonyl compounds using imidazolidine based catalysts 10 and 222.

The mode of asymmetric induction of these catalysts was rationalised by comparing the calculated energy for the various iminium ion intermediates 223-226. ${ }^{16}$ PM3 semi
empirical calculations suggested that the trans-iminium ions 224 and 226 were considerably higher in energy ( $>3 \mathrm{kcal} / \mathrm{mol}$ ) than $\mathbf{2 2 3}$ and $\mathbf{2 2 5}$ due to unfavourable steric interactions. Iminium ions $\mathbf{2 2 3}$ and $\mathbf{2 2 5}$ were of similar energy although $\mathbf{2 2 3}$ was slightly favoured.

(Figure 7.1)

Constructing a model of iminium ion $\mathbf{2 2 3}$ demonstrates that the $R e$-face of the iminium ion intermediate was blocked by the benzyl group of the catalyst and that the Si-face was more exposed to nucleophilic attack (Figure 7.2). The proposed theoretical model was consistent with the observed asymmetric induction of the products determined by X-ray crystallography.

(Figure 7.2)
In particular, we were attracted by the Michael addition of nitroalkanes to $\alpha, \beta$ unsaturated ketones principally due to the formation of the a $\mathrm{C}-\mathrm{C}$ bond and the numerous
$\qquad$
subsequent elaborations possible with the nitro group. Catalyst $\mathbf{1 0}$ took the reaction to $100 \%$ conversion with $79 \%$ e.e. over a period of 240 h with $20 \mathrm{~mol} \%$ catalyst loading. The reaction times for a number of the reported transformations were extremely long (up to 300 h ) to achieve modest yields. Therefore, we chose a system that was comparatively rapid to allow us to obtain our proof of concept (Scheme 7.4).

(Scheme 7.4)

The catalytic cycle for this transformation begins with condensation of the secondary amine with the enone 227 to generate the iminium ion 230 (Scheme 7.5). The Michael acceptor is now sufficiently activated for attack by the nucleophile. In this case, the deprotonated nitropropane $\mathbf{2 2 8}$ reacts. Upon attack of the nucleophile, the enamine $\mathbf{2 3 2}$ is formed. The catalytic cycle is then completed by hydrolysis of the enamine to yield the product 229 and regenerate the catalyst.

(Scheme 7.5)

The proposed mechanism for the reversible Michael addition would begin by iminium ion formation by condensation of the secondary amine catalyst with the carbonyl of Michael adduct 229. The resulting iminium would then form the enamine 232. Donation of the lone pair of the nitrogen to form an iminium ion would displace electrons that in turn would displace the nitropropane anion 231 to generate the activated Michael acceptor 230. The iminium ion could then be hydrolysed or undergo a Michael addition to reform 229 (Scheme 7.6).

### 7.2.1 Experimental Design

In order to demonstrate the potential for dynamic resolution we designed three experiments that would give us proof of concept, or at least demonstrate the reversibility of the organocatalysed Michael addition.

## Experiment I

The first and the most attractive would be to take a racemic Michael addition product from an organocatalysed reaction and submit this product to the optimal literature conditions for the asymmetric organocatalytic procedure in the presence of a chiral catalyst such as $\mathbf{1 0}$ (Scheme 7.7).

(Scheme 7.7)

The observation of an increased e.e. in the Michael addition product would clearly indicate that intermediate $\mathbf{2 3 0}$ must have been formed with the reaction.

## Experiment II

Another experiment very similar to experiment II, but less desirable, would be to subject an enantioenriched Michael addition adduct to an achiral catalyst under optimal reaction conditions and detect a decrease in the observed e.e. of the Michael adduct. As with experiment I this would clearly indicate that the intermediate iminium ion $\mathbf{2 3 0}$ must have been formed under the reaction conditions.

## Experiment III

The third experiment would be to take the product of the Michael addition of a nucleophile and submit it to reaction conditions used for introducing an alternative nucleophile (Scheme 7.8). Detection of 234 would strongly indicate that the reaction was reversible as direct substitution would be unlikely.

(Scheme7.8)

### 7.2.2 Selection of Catalyst for the Study

Our preferred choice of asymmetric catalyst was the imidazolidine 10. In order to begin the research we had to prepare $\mathbf{1 0}$ which proved more difficult than expected. Preparation of $\mathbf{2 3 5}$ was straightforward and consistent with the literature. However, the cyclisation to afford 10 proved difficult and time consuming with many attempts conducted. It was found, however, that the glyoxylic acid starting material was the problem and on purchase of a fresh batch the synthesis was completed (Scheme 7.9).

Chapter 7 $\qquad$ TJ K Gibbs- PhD Thesis 2008

(i) $\mathrm{NH}_{2} \mathrm{Me}$ (5 eq) in $\mathrm{EtOH}, 16 \mathrm{~h}, \mathrm{rt} 89 \%$.(ii) $\mathrm{LiAlH}_{4}$ (10 eq), THF, 16 h , reflux, $25 \%$. (iii) $\mathrm{CHOCO}_{2} \mathrm{H}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 16 \mathrm{~h}, \mathrm{rt}, 62 \%$.
(Scheme7.9)

We also required an achiral catalyst for Experiments II and III and therefore we proposed to use hydrazide catalyst 91 previously developed in the group as it was known to catalyse Michael addition reactions. ${ }^{136}$ However, 91 proved inactive for the reaction of nitroalkanes with enones as the HCl salt and the free base. We also attempted using the MacMillan catalyst 7 to subsequently allow for preparation of an achiral variant but this also proved inactive. This may be for two reasons firstly; the catalysts were only sparingly soluble under reaction conditions. Secondly, the $\mathrm{pK}_{\mathrm{a}}$ of the co-acid may have been too low as the majority of active catalysts for this transformation contain an internal carboxylic acid with a higher $\mathrm{pK}_{\mathrm{a}}(\approx 4)$. It is important to stress, however, that these organocatalysed Michael additions are slow, even under optimal conditions and therefore we could only realistically screen for the most active catalysts for this class of transformation.

We therefore targeted compound 237 as an achiral catalyst as it was structurally very similar to the chiral Jørgensen catalyst $\mathbf{1 0}$ and therefore should posses similar activity and be accessible by an analogous synthetic approach to catalyst $\mathbf{1 0}$.

However, compound 237 proved elusive although much synthetic effort was deployed developing reaction conditions. In hindsight the most probable reason for this was a similar reaction to that discussed in (Chapter 8), however, due to the complex mixture of products obtained this was not clearly evident at the time. We therefore decided to use proline 236 as our 'achiral' catalyst as it was successful in catalysing the Michael addition reaction of nitropropane 228 and eneone 227 with low selectivity (e.e. $\approx 7 \%$ ).

### 7.2.3 Obtaining the Compounds for the Experiments

Having found suitable catalysts $\mathbf{1 0}$ and $\mathbf{2 3 6}$ for this investigation, in order to conduct experiments I-III outlined earlier we need access to sufficient quantities of chiral and racemic Michael addition products. We obtained our chiral Michael addition product 229 by conducting the procedure reported by Jørgensen. Due to the lack of information in the literature on achiral organocatalysed Michael additions we obtained our racemic product 237 (equivalent to the reaction of $\mathbf{2 2 9}$ and nitromethane 238) from an efficient proline catalysed conjugate addition of acetone to trans-nitrostyrene 239 (Scheme 7.10). ${ }^{137}$

### 7.2.4 Establishing a Method of Analysis

In his work Jørgensen determined the enantiomeric excess of the Michaels adducts using GC with a chirasil Dex-CB chiral stationary phase. ${ }^{16}$ Without this apparatus we had to develop a novel procedure for analysis. To achieve this we repeated Jørgensen's procedure for the reaction and determined the e.e. by chiral phase HPLC. Comparing our observed values with those of the literature allowed us to validate our method and deduce the retention times of each enantiomer by analogy. An analogous procedure was conducted to establish the HPLC conditions for compound 237 using data provided by List (see Appendix). ${ }^{137}$

### 7.3 Results and Discussion

### 7.3.1 Reversibility Experiments

To satisfy the criteria of experiment I (Section 7.2.1) we took compound ( $\pm \mathbf{2 3 7}$ along with catalyst 10 and applied the reaction conditions provided for the transformation by Jørgensen. After a generous reaction time of 240 h the reaction was stopped, columned
$\qquad$
and analysed by HPLC. Disappointingly, the e.e. observed for the Michael addition adduct 237 was identical to the starting material ( $7 \%$ ). Therefore, it can be concluded that this reaction is effectively irreversible at this time scale.

(Scheme 7.11)

To achieve proof of concept using experiment II we took the enantioenriched product 229 and subjected it to $D$-proline, $L$-proline and ( $\pm$ )-proline individually in 2-nitropropane for 3 weeks. Again, the e.e. of the products, determined by HPLC, obtained for all three catalysts was identical to that of the starting material.

(Scheme 7.12)

Experiment III was conducted using the racemic compound ( $\pm$ ) 237 which was stirred in diethyl malonate 240, ethylacetoacectate 241 and nitropropane 228 in the presence of proline 236 for one week (Scheme 7.13).

$\qquad$

Spectroscopic analysis provied no indication of the new products and the initial mass of racemic adduct was recovered. This experiment also indicated that the reaction was not reversible.

### 7.3.2 Effect of Methanol on Reaction Rate Of Michael Additions

The organocatalysed Michael additions involving nitroalkanes frequently use the nitroalkane as the solvent. In our investigations we made the observation that the catalyst did not appear to be well solubilised under the reaction conditions which could possibly explain the sluggish rate of reaction. We therefore added a small amount of methanol to see if this would accelerate the rate of reaction by making the catalyst more available in solution.

This proved successful and we managed to considerably lower the reaction time. In order to quantify this effect we did series of experiments where we altered the relative amount of methanol and nitroalkane (Figure 7.3).

We discovered that the optimal amount of methanol for the reaction was $60 \%$ (V/V $\mathrm{MeOH} / \mathrm{CH}_{3} \mathrm{NO}_{2}$ although a similar acceleration was observed for $20 \%$ added methanol. Interestingly, addition of $>60 \%$ methanol had a detrimental effect on the rate but was still superior than the levels of activity observed in the absence of co-solvent. An explanation for these observations may be that on addition of a greater portion of methanol there are fewer molar equivalents of nitropropane available for reaction, hence slowing the rate. This data suggested that with between $20-60 \%$ added methanol that all the catalyst was in solution. This was consistent with the physical observation of the transformation.

With these results in hand we believed that we might be able to accelerate the rate of the reactions and therefore added $60 \%$ methanol to reaction with the chiral 10. Disappointingly, a significantly lower e.e. ( $21 \%$ compared to $80 \%$ ) was observed rendering the discovery obsolete as a method to accelerate the rate of this class transformation.

It is noteworthy, that although the published catalyst loadings for these transformations is $20 \mathrm{~mol} \%$, in fact only a small fraction of this amount can be involved in the actual reaction due to an inherent lack of solubility of the catalyst.

### 7.3.3 Investigation of Alternative Catalysts for the Retro-Michael Reaction

Although we had failed to demonstrate the reversibility of the Michael addition with the published chiral catalyst $\mathbf{1 0}$ or proline $\mathbf{2 3 6}$ we rationalised that the requirements for a catalyst for the reverse reaction may be different to that of the forward reaction. There are examples in the literature of multiple organocatalysts selectively accelerating different reactions within a single reaction vessel. ${ }^{138}$ We believed that we could exploit this concept to develop a dynamic resolution procedure. In order that an amine be efficient at facilitating the retro-Michael reaction, we rationalised that greater electron density associated with the lone pair of the nitrogen is desirable to facilitate elimination of the nucleophile(Scheme 7.14).

(Scheme 7.14)

To achieve our aims we selected a range of simple commercially available secondary amines with inductive electron donating groups. We also believed that the $\alpha$-effect could encourage the retro-Michael reaction. We therefore selected a range of commercially available amines which would allow us to test this hypothesis (Figure 7.4).

242

243

69

244

68

66
(Figure 7.4)

Initially, we examined the catalysts in the forward reaction of eneone 227 with nitromethane with $60 \%$ added methanol. No reaction was observed for any of the catalysts 242-244, 66, 68 and 69 after a 48 h period.

Having established that the catalysts $\mathbf{2 4 2 - 2 4 4}, \mathbf{6 6}, 68$ and 69 would not rapidly catalyse the Michael addition we sought to discover whether they could catalyse the retro-Michael reaction. We submitted compound 237 to the catalysts $242-244,66,68$ and 69 at 20 $\mathrm{mol} \%$ loading in deuterated solvent and monitored the reaction mixtures by ${ }^{1} \mathrm{H}$ NMR over a period of 7 d for the presence of eneone 227 . The presence of 227 was not observed in the ${ }^{1} \mathrm{H}$ NMR spectra for any of the catalysts. Furthermore, the initial spectrum was identical to all subsequent spectra. We therefore concluded that none of the catalysts employed could facilitate a retro-Michael addition reaction.
$\qquad$

### 7.3.4 Iminium Ion Activation vs $\mathbf{H}$-Bonding Activation

Subsequent to our investigations we became aware of work conducted by Lattanzi investigating the organocatalytic expoxidation of $\alpha, \beta$-unsaturated ketones using peroxides (Scheme 7.15). ${ }^{139}$

(Scheme 7.15)

Within this work Lattanzi conducted non linear studies and from the results postulated that catalyst 247 was acting as a bifunctional catalyst by simultaneously activating the ketone 245 and the peroxide 246 as outlined in the proposed catalytic cycle below (Scheme 7.16).

(Scheme 7.16)

The cycle is initiated through deprotonation of the peroxide 246 by catalyst 247 to form the active peroxide anion 250 and the corresponding ammonium cation 249 which forms a tight ion pair in the non-polar hexane medium. It was then believed that the hydroxyl group of the catalyst activates the $\alpha, \beta$-unsaturated ketone through hydrogen bonding via the transition state 251. Electrostatic interactions then arrange the reaction components to allow for the conjugate addition of peroxide anion $\mathbf{2 5 0}$ to form a hydrogen bond stabilised enolate, which subsequently attacks the $\mathrm{O}-\mathrm{O}$ bond of the peroxide
intramolecularly generating the epoxide 248, ammonium species 249 and the tert-butoxide anion 252. The final step is regeneration of the catalyst 247 by deprotonation with the tert-butoxide anion 252.

We began to consider whether catalyst $\mathbf{1 0}$ could be acting in a similar manner activating the $\alpha, \beta$ unsaturated carbonyl by hydrogen bonding (254) rather than activation via iminium ion formation (253) to nucleophiles (Figure 7.5).

10

253

254
(Figure 7.4)

It is noteworthy that there has been no evidence presented that confirms the occurrence of iminium ion 253 within the organocatalysed Michael additions reported by Jørgensen. Through conducting our work we have not observed any indication of the presence of iminium ion 253 although we did not explicitly look for it. What is significant is that within our iminium ion catalysed Diels-Alder work, where we conducted detailed studies of iminium ions (Chapter 2-5), the presence of an iminium ion was clearly indicated by a strong yellow colour within the reaction. This yellow colouration was not observed within this Michael addition investigation. This argument may be easily discounted as the reaction medium and substrates have been altered considerably. It is also noteworthy that catalyst 91 which is known to be efficient at catalysing Michael additions to $\alpha, \beta$ unsaturated aldehydes through iminium ion activation is inactive in this transformation. ${ }^{140}$

(Figure 7.5)

It may also be significant that the addition of MeOH as a co-solvent in the reaction increased the activity. This was thought to be due to solubility of the catalyst but it may well be that the MeOH present is contributing to the activation of the $\alpha, \beta$-unsaturated ketone through hydrogen bonding. This is certainly consistent with the loss of asymmetry induced by adding MeOH (see section 7.3.2).

To discover whether or not catalyst 10 operates via iminium ion activation or through hydrogen bonding activation would require further experiments to be conducted. These additional experiments should be relatively straightforward to perform and certainly worthwhile.

### 7.4 Conclusions

Despite significant efforts to demonstrate the concept of dynamic resolution for the organocatalysed Michael addition reactions, proof remains elusive. It can be concluded that these reactions are effectively irreversible within the timescales that our experiments were conducted. Often, the forward organocatalysed Michael additions take several days for the reaction to achieve good yields. It has been shown that after an extended period of time excellent yields are obtained for these reactions (ca $>95 \%$ ). ${ }^{16}$ If these yields do in fact represent the equilibrium positions of the reactions, that suggests that the rate of the retro-Michael reaction is extremely slow given the sluggish rate at which the forward reaction takes place. It is primarily the slow rates of the organocatalysed Michael additions that will inevitably limit the practicality of any resolution procedure developed with the substrates used.

Chapter 8: Development of a Practical Method for the Carboxymethylation of Primary Amines ${ }^{141}$

### 8.1 The Aims of the Research

In this study we sought to explore the scope of a serendipitously discovered monocarboxymethylation reaction of primary amines. We then sought to extend our methodology to selectively synthesise piperazinones from diamines.

### 8.2 Introduction

In an attempt to synthesise catalyst $\mathbf{2 5 6}$ by reaction of glyoxylic $\mathbf{2 5 5}$ acid with $\mathbf{1 3 8}$, for a project investigating organocatalysed Michael additions (Chapter 7), great difficulty was encountered in interpretation of the spectroscopic data obtained for the product.

(Scheme 8.1)

The ${ }^{1} \mathrm{H}$ NMR data appeared to be generally consistent with a diastereotopic mixture of the isomers of 256a-b. However, mass spectrometry failed to find the molecular ion for compound 256. Not confident as to its structure we submitted the unidentified product as a catalyst for a Michael addition reaction in which it proved inactive. We therefore lost interest in the compound as a catalyst. Still unsure as to the compound's identity we attempted to grow crystals suitable for X-ray crystallography studies. The structure that was determined for the compound was that of $\mathbf{2 5 7}$ (Figure 8.1).

257

(Figure 8.1)

The result obtained was completely unexpected. Examining this result we rationalised that compound $\mathbf{2 5 7}$ must have reacted with two equivalents of glyoxylic acid $\mathbf{2 5 5}$ to give
compound 257. In order to establish whether the reaction was reliable we reacted phenethylamine 258 with glyoxylic acid 255 ( 2 eq ) and obtained the corresponding product 259 (63\%).

(Scheme 8.2)

Suitable crystals were also grown of this compound and X-ray crystallography confirmed that we had the desired product 259 (Figure 8.2).

(Figure 8.2)
A literature search revealed that a monocarboxymethylation reaction of primary amines with glyoxylic acid had been previously reported. ${ }^{142}$ However, we realised that the conditions used in the reported process were relatively harsh utilising formic or trifluoroacetic acid as the reaction medium at elevated temperatures $\left(60-100^{\circ} \mathrm{C}\right)$. The reaction that we had observed took place in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at room temperature, presenting the opportunity to develop a mild and efficient method for the monocarboxymethylation of primary amines.

### 8.2.1 Potential Extension to Synthesise Piperazinones for Peptidomimetics

We hypothesised that the transformation had the potential to be developed as an efficient method for the formation of piperazinones 260 using diamines 261 and glyoxylic acid 255 as outlined below (Scheme 8.3).

(Scheme 8.3)

The piperazinone ring as a structural motif is of importance in the field of peptidomimetics. The concept of peptidomimetics is to mimic the properties of peptides with therapeutically active compounds of a similar structure that have superior receptor binding ability while being metabolically stable within the physiological system. An example of a therapeutic agent based around a central piperazinone is TAK-024 264 (Figure 8.3). ${ }^{143}$

(Figure 8.3)

It is the potential of this class of peptidomimetic that fuels much of the research into the development of novel and efficient methods for the preparation of 2-piperazinones. A method frequently employed for the monocarboxymethylation of primary amines involves the use of $\alpha$-halo carboxylic acids and esters 265 (Scheme 8.4)

(Scheme 8.4)

However, these reactions are often inefficient due to the over alkylation of the amine which leads to compounds such as 267 . This can be overcome using protecting group strategies or adding an excess of the amine but both are undesirable in a multi-step synthesis. Therefore, methods providing a selective monocarboxymethylation are desired prompting our attempts to develop the reaction further.

### 8.3 Results and Discussion

### 8.3.1 The Mechanism

We began by considering the mechanism of the reaction. We believed that the first step of the reaction was formation of imine 269 by condensation of the amine 258 and a molecule of glyoxylic acid $\mathbf{2 5 5}$. The imine then uncharacteristically acts as a nucleophile attacking a second molecule of glyoxylic acid $\mathbf{2 5 5}$ to yield iminium ion intermediate 270. This intermediate was believed to decarboxylate evolving $\mathrm{CO}_{2}$ (which is consistent with experimental observations.) The resulting enolate 271 can then be protonated restoring the carboxylic acid group while the iminium ion converts to the corresponding formamide to produce the observed structure 272.

It is noteworthy that the glyoxylic acid $\mathbf{2 5 5}$ cannot be acting as a hydride source, in an analogous manner to formic acid reductions, due to the stoichiometry used within the reaction and the corresponding yields obtained.

### 8.3.2 Solvent Screen

Having realised the potential of the reaction we set about developing optimal conditions for the transformation. We selected the reaction of phenethylamine 258 and glyoxylic acid $\mathbf{2 5 5}$ as our standard, reacting for 24 h at 0.2 M in a range of solvents (Table 8.1).

(Scheme 8.6)

| Entry $^{\mathrm{a}}$ | Solvent | conversion \% |
| :---: | :---: | :---: |
| 1 | $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ | 72 |
| 2 | $\mathrm{Et}_{2} \mathrm{O}$ | 49 |
| 3 | EtOAc | 64 |
| 4 | MeOH | 23 |
| 5 | MeCN | 45 |
| 6 | PhMe | 43 |
| 7 | THF | 30 |
| 8 | $\mathrm{H}_{2} \mathrm{O}$ | 75 |
| $9^{\mathrm{b}}$ | $\mathrm{H}_{2} \mathrm{O}$ | 77 |

(a) Glyoxylic acid monohydrate $99 \%$
(b) $50 \% \mathrm{w} / \mathrm{v}$ of glyoxylic acid solution used
(Table 8.1)

The conversions were within $5 \%$ of the isolated yield of hydrolysed compound indicating the validity of the method for rapid analysis. The reaction tolerated a wide range of solvents with only MeOH (Table 8.1, entry 4) and THF (Table 8.1, entry 7) providing unsatisfactory yields in 24 h . This was most probably due to minor side reactions, as discolouration was observed in the reaction with these solvents. It was found that the optimal solvent was $\mathrm{H}_{2} \mathrm{O}$. This observation allowed us to develop a one-pot method for the monocarboxymethylation of primary amines as aqueous acid could be directly added to the reaction vessel to hydrolyse the formyl group after initial reaction. (Scheme 8.6). The method previously described involved isolation of the crude formamide intermediate before conducting the hydrolysis.

(Scheme 8.6 )

We also examined the use of a commercially available solution of $50 \% \mathrm{w} / \mathrm{v}$ glyoxylic acid in $\mathrm{H}_{2} \mathrm{O}$. Slightly better conversions were obtained (within experimental error) using the glyoxylic acid solution providing a more economical and convenient procedure.

### 8.3.3 Reaction with Primary Amines

Having established the optimal reaction conditions from our solvent and determined that we could conduct a subsequent hydrolysis in a single vessel, we set about discovering the substrate scope. Initially, we reacted a number of primary amines with glyoxylic acid which led to compounds 273-279 in good to excellent yields (Table 8.2).
Entry ${ }^{\text {Product }}$
(a) Reactions conducted at stated temperature in $\mathrm{H}_{2} \mathrm{O}$ for 24 h with 2.2 equivalents of glyoxylic acid. (b) A refers to hydrolysis in 1 M HCl at reflux for $18 \mathrm{~h}, \mathrm{~B}$ refers to hydrolysis with 2 M HCl at reflux for 18 h .
(Table 8.2)

The reaction was shown to tolerate primary (Table 8.2, entry 1) and secondary (Table 8.2, entry 2) $\alpha$-substituted amines with good yield. The lack or reactivity of tert-butyl amine (Table 8.2, entry 8) is most likely due to the steric bulk of the tert-butyl group hindering formation of the imine intermediate under the reaction conditions as the amine was present after reaction. Benzylamine reacted to give benzyl protected glycine 277 in 50\%
yield (Table 8.2, entry 4). Reactions with para-substituted benzylamines containing electron donating methoxy and electron withdrawing chloro groups 278 and 279 , respectively, were successful (Table 8.2, entry 5 and 0 ). The reaction also tolerated allyl amine albeit with poor yield (Table 8.2, entry 3). Ethanolamine reacted with glyoxylic acid but the ${ }^{1} \mathrm{H}$ NMR indicated that numerous compounds had formed with isolation of the desired product proving too difficult.

The reaction of $N$-methyl benzylamine (Table 8.2, entry 10) and triethylamine (Table 8.2, entry 11) with glyoxylic acid yielded no products demonstrating the chemospecificity of the process for primary amines, a distinct advantage over other methods. This observation also provided further evidence for our proposed mechanism.

### 8.3.4 Reactions with Diamines

Having demonstrated that the reaction was efficient with a range of primary amines we set about reacting a series of 1,2 and 1,3 diamines with glyoxylic acid 255 . There are several possibilities for the course of the reaction of ethylene diamine with glyoxylic acid. For example, the monocarboxymethylation of a single amine (284), alternatively both amines could undergo a monocarboxymethylation reaction (285). A further possibility is that after monocarboxymethylation of a single amine an intramolecular cyclisation might occur to give piperzinone 260. Dimerisation and polymerisation were also possible but less likely as it involves a more challenging intermolecular reaction (Scheme 8.7).

(Scheme 8.7)

On analysis of the reaction of ethylenediamine and glyoxylic (4 eq) acid we had to establish which product we had obtained. ${ }^{1} \mathrm{H}$ NMR allowed us to discount structures 285 and 286 as the correct structure. However, mass spectrometry failed to detect the molecular ion for either of structures $\mathbf{2 6 0}$ or $\mathbf{2 8 4}$. Therefore, the correct structure $\mathbf{2 8 4}$ was determined by analogy to the commercially available product by comparing samples using ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR as well as melting point and IR spectroscopy. Mass spectrometry also failed to detect the molecular ion of the commercially available sample. Products 284, 287-290 were easily characterised by conventional techniques.

(a) Reactions conducted at $25^{\circ} \mathrm{C}$ in $\mathrm{H}_{2} \mathrm{O}$ for 24 h. (b) Conditions A refers to hydrolysis with 1 M HCl at reflux for $18 \mathrm{~h}, \mathrm{~B}$ refers to hydrolysis with 2 M HCl at reflux for 18 h .
(Table 8.3)

Although the yields obtained are only moderate attempting the monocarboxymethylation of these diamine substrates with $\alpha$-halo acids/esters would undoubtedly produce even lower yields with numerous by-products forming.

Disappointingly, no evidence of a piperazinone was observed. However, further attempts within the group have subsequently been successful in synthesising piperazinone 260 from N -methyl ethylenediamine by altering the reaction conditions.

### 8.4 Conclusions

In summary, we have developed a mild and efficient method for a one-pot monocarboxymethylation of primary amines and diamines. The reaction is selective for primary amines without the need for protection of more nucleophilic secondary amines and can tolerate a range of amines. The reaction with ethylene diamine provides access to the monocarboxymethylated product in $31 \%$ isolated yield on addition of 4 equivalents of glyoxylic acid providing a remarkably selective process. This method has been subsequently been developed to allow for the synthesis of piperazinones.

# Chapter 9: An Aminocatalytic Method for the Preparation of bis-Indoyl Alkanes ${ }^{144}$ 

### 9.1 Introduction

The importance of indoles as a structural motif in organic chemistry is well documented. ${ }^{145}$ The indole unit is present in the naturally occurring and abundant amino acid tryptophan and is consequently found in many compounds of natural origin. Within this chapter an aminocatalytic method for the synthesis of a variety of bis-indole containing natural and non natural targets is reported.

### 9.1.1 Discovery

At the heart of much chemical research is the search for new synthetic methods. We began this research with a view to expand the existing reaction portfolio of iminium ion catalysed processes. Iminium ions have been successful in catalysing numerous reactions that traditionally utilise Lewis acids. With this in mind our attention was drawn to a Lewis acid catalysed process where nucleophilic attack of $N$-methyl indole facilitated cyclopropyl ring opening in a C-C bond forming process (Scheme 9.1). ${ }^{146}$

(Scheme 9.1)

To establish whether a similar procedure could be achieved using secondary amine catalysis we conducted a reaction between $N$-methylindole 291 and cyclopropyl carboxaldehyde 292 utilising catalyst 91 previously developed within the group (Scheme 9.2).

(Scheme 9.2)

It was evident from the appearance of the reaction mixture that reaction had taken place. However, on analysis of the purified product it was clear that an unexpected reaction had occurred (Scheme 9.3).

(Scheme 9.3)

The spectroscopic data measured for the product was consistent with that of compound 294. Consulting the literature we found that this class of compound was known and that frequently they have a natural origin.

### 9.1.2 Biological Significance and Reported Procedures

Bis-indolylalkanes as a structural class contain some biologically important molecules. For example, diindolylalkane 295 has been identified as being active at promoting beneficial oestrogen metabolism in men and women ${ }^{147}$ and has also been found to trigger apoptosis in human breast cancer cells. ${ }^{148}$ The biological activity of these compounds has prompted numerous research groups to develop methods for their preparation.

It has been reported that bisindolyl alkanes can be prepared using both Brønsted and Lewis acids to activate the carbonyl to attack by indole. Recent reports include the preparation of bisindolyl alkenes through heterogeneous catalysis using zeolites ${ }^{149}$ and montmorillonite $\mathrm{K} 10 .{ }^{150}$ Lewis acids that have been utilised include $\mathrm{Zr}(\mathrm{OTf})_{3}$, ${ }^{151}$ $\mathrm{La}(\mathrm{PFO})_{3}{ }^{152}$ and $\mathrm{CeCl}_{3}$. ${ }^{153}$ The Brønsted catalysts reported include Amberlyst resins ${ }^{154}$ and molecular iodine, ${ }^{155}$ along with $\mathrm{KHCO}_{3}{ }^{156}$ also having reported as a catalyst. Of the
catalysts listed above, it is the heterogeneous catalysts that appear to be the most efficient with reaction times $10 \mathrm{~min}-6 \mathrm{~h}$. However, large quantities of catalyst have to be used to accelerate the reaction with up to $9100 \% \mathrm{w} / \mathrm{w}$ of catalyst with respect to the aldehyde. To date there has been no report of secondary amines catalysing the reaction. We therefore set out to discover the potential of our aminocatalytic method for the preparation of bisindolyl alkanes.

### 9.2. Results and Discussion

### 9.2.1 Proposed Mechanism

The initial work established the need for a secondary amine catalyst 91 in order for reaction to occur (Table 9.1, entry 1). Therefore, we conducted control reactions conducting the addition with no catalyst (Table 9.1, entry 2), triethylamine hydrochloride (Table 9.1, entry 3) and also acetic acid (Table 9.1, entry 4). These control reactions yielded no product, as expected, confirming that our catalyst 91 was responsible for the reactivity.

To explain the reactivity we proposed a mechanism where the activated iminium ion 296 formed by condensation of the secondary amine catalyst 91 and the carbonyl 298. The iminium ion 299 is significantly more electrophilic than the corresponding aldehyde and therefore undergoes attack by the indole $\mathbf{3 0 0}$ to form the amine 301. Protonation of the tertiary amine would allow for the lone pair of the indole nitrogen to push through the conjugated $\pi$-systems to eliminate and regenerate the catalyst 91. The resulting $\alpha, \beta$-unsaturated iminium ion 302 is sufficiently activated to undergo a nucleophilic Michael-type addition by a second molecule of indole $\mathbf{3 0 0}$ followed by rearomatisation of the indole to yield the observed product 303 (Scheme 9.4).

(Scheme 9.4)

It is thought that addition of the first indole is most likely to be the rate determining step. The tentative evidence for this is that the only compounds observed in the reaction mixture were the starting materials and the products. Attempts to facilitate mono addition of the indole by reducing the temperature and adding substoichiometric amounts of indole proved unfruitful; however, these studies were far from rigorous and comprehensive.

### 9.2.2 Effect of Solvent on Reaction

To discover the optimal solvent for the reaction we conducted a brief solvent screen. The reaction of propionaldehyde 304 and indole 300 with $5 \mathrm{~mol} \%$ loading of catalyst 91 for a 24 h period was examined with a variety of solvents (Table 9.2).

Acetonitrile was the worst solvent and failed to facilitate any significant reaction after a 24 h period (Table 9.2, entry 1). Polar solvents such a DMF, DMSO and $\mathrm{H}_{2} \mathrm{O}$ (Table 9.2, entries 2, 3 and 4) all gave the product 305 in similar yields $55-62 \%$. MeOH and THF (Table 9.2, entries 6 and 7) were less efficient as solvents, providing yields of 33 and $39 \%$ respectively.

It was MeOH that we selected as our solvent of choice (partly as we had synthesised a number of compounds in MeOH prior to commencing the solvent screen) as it was operationally simpler to use in the reaction than DMF, DMSO and $\mathrm{H}_{2} \mathrm{O}$. Using MeOH also provided the advantage that upon reaction a precipitate was observed for many of the substrates allowing a rapid qualitative indication of successful reaction. This precipitation was not apparent in THF for any substrate.

### 9.2.3 Variation of the Indole

Having established that the reaction worked for a few examples we sought to discover the tolerance of the reaction with derivatised indoles. We selected indole $\mathbf{3 0 0}$ as the standard, $N$-methylindole 291, 5-methoxyindole 306, 5-nitroindole 308 and 5-chloroindole 307 (Figure 9.1).

300

291

306

307

308
(Figure 9.1)

Propionaldehyde 304 was chosen as the reaction partner to allow direct comparison of the relative reactivity of the indoles (Scheme 9.5).

(Scheme 9.5)

No reaction occurred between 5-nitroindole 308 and propionaldehyde 304 after a 24 h period. The electron withdrawing effect of the nitro group considerably reduces the nucleophilicity of the indole and therefore reduces activity. The reaction did however tolerate the weaker EWG leading to 5-chloroindole derivative 311 in $42 \%$ yield after a

24 h period. Addition of an alkyl group on the nitrogen of the indole had little effect on reactivity. The reactions with indole 300 and $N$-methylindole 291 with propionaldehyde 304 gave the expected products in 84 and $81 \%$ yield, respectively, after 24 h . The reaction also tolerated electron donating groups on the indole unit, 5-methoxyindole 306 reacted with propionaldehyde 304 to give the adduct 310 in 55\% yield.

### 9.2.4 Variation of the Aldehyde

304

292

312

313
(Figure 9.2)

After our initial success in reacting a series of indoles we wanted to discover which carbonyl substrates would be tolerated. Four aldehydes were reacted with indole, propionaldehyde (304), cyclopropanecarboxaldehyde (292), benzaldehyde (312) and 4hydroxybenzaldehyde (313) to give the products $\mathbf{3 0 5}$ and $\mathbf{3 1 4 - 3 1 6}$ in $74-89 \%$ yield (Scheme 9.0).

(Scheme 9.6)
$\qquad$

### 9.2.5 Reaction with Ketones

(Scheme 9.7)
Many of the examples in the literature to prepare bis-indolylalkanes did not report ketones as substrates. We therefore examined the more challenging ketone substrates within this organocatalysed reaction. In total three ketones were tested, methyl cyclopropyl ketone 317, cyclohexanone 318 and cyclohexandione monoethylene ketal 319 with indole 300. Methyl cyclopropyl ketone was also reacted with $N$-methylindole 291.

The reactions were all successful furnishing compounds $\mathbf{3 2 0 - 3 2 3}$ as the products. Indole 300 and $N$-methylindole 291 reacted with identical efficiency with methyl cyclopropyl ketone providing both $\mathbf{3 2 2}$ and $\mathbf{3 2 3}$ in $69 \%$ isolated yield. Reaction of cyclohexanone $\mathbf{3 1 8}$ with indole $\mathbf{3 0 0}$ gave the product $\mathbf{3 2 0}$ in $58 \%$ yield after 24 h . Pleasingly, compound $\mathbf{3 2 1}$ was also obtained in $50 \%$ yield from the corresponding ketone displaying that our synthetic method could tolerate the acid sensitive ketal functionality. Synthesis of $\mathbf{3 2 1}$ using the reported Brønsted and Lewis acid methods would in our opinion present a greater challenge. It is also noteworthy that the modest $50 \%$ isolated yield obtained for

321 is most likely a consequence of slower reactivity rather than side reactions or hydrolysis of the ketal (determined qualitatively by TLC).

### 9.2.6 Naturally Occurring Bis and Tris-Indolylalkanes

Having established that we had discovered a mild and efficient method for the synthesis for a range of bisindolylalkanes from aldehyde and ketone substrates we set about applying our methodology to synthesise a variety of naturally occurring compounds. There have been numerous bisindolylalkane natural products isolated and described. ${ }^{157}$ Examining the literature we selected four targets to test our methodology 324-327 (Figure 9.3).

80\%
324

77\%
325

$72 \%$
326

$51 \%$
327
(Figure 9.3)

Vibrindole A 324 was first identified as a metabolite from the marine bacterium vibrio paraheamolyitcus and has also been detected in other marine organisms. ${ }^{158}$ Our preparation afforded Vibrindole A 324 in $80 \%$ yield after a 24 h period under our standard reaction conditions at room temperature in methanol for 24 hours using $10 \mathrm{~mol} \%$ of catalyst 91.

The naturally occurring compounds 325,326 and 327 were all isolated from the marine bacterium vibrio paraheamolyitcus. ${ }^{159}$ The tris-indolylalkane 325 was obtained by reaction of 3-indolecarboxaldehyde with 2 equivalents of indole in a respectable $77 \%$ yield. Compound $\mathbf{3 2 6}$ was synthesised by reaction of isatin with 2 equivalents of indole in $72 \%$ yield. The reaction of isatin at the ketone rather than the less reactive amide confirms the chemoselectivity of this process for aldehydes and ketones.

The highlight of our synthetic work was the synthesis of compound 327. Previous experiments in the group had demonstrated that catalyst 91 could catalyse Michael additions to $\alpha, \beta$-unsaturated carbonyl compounds. We recognised the opportunity to introduce the three indoles in one reaction vessel. This method was successful and gave 327 in a respectable $51 \%$ yield forming three $\mathrm{C}-\mathrm{C}$ bonds in one pot.

(Figure 9.4)

The first step in the mechanism is formation of the $\alpha, \beta$-unsaturated iminium ion $\mathbf{3 2 8}$ which then undergoes the Michael addition reaction with a molecule of indole to give enamine 329. The resulting enamine is in equilibrium with the corresponding iminium ion 330 which reacts by the same mechanism outlined above (Scheme 9.4) to give the product 327 (51\%).

### 9.2.7 Catalyst Loading

To establish the activity of our catalyst in the transformation we conducted the reaction between benzaldehyde $\mathbf{3 1 2}$ and 2 equivalents of indole $\mathbf{3 0 0}$ in the presence of $1 \mathrm{~mol} \%$ of 91.

(Scheme 9.9)
The yield obtained after a 32 h period was $84 \%$ suggesting that catalyst 91 is particularly active for this transformation.

### 9.3 Conclusions

We have demonstrated the first aminocatalytic method for the preparation of bis and tris indolylalkanes. A variety of indoles, aldehydes and ketones are tolerated as substrates with acid sensitive groups such as ethylene ketals being compatible with the reaction conditions. The method was applied to the synthesis of a range of naturally occurring compounds including vibrindole $A$. The methodology can be further extended to facilitate a tandem Michaeladdition-bis-alkylation reaction in one-pot forming a total of three new C-C bonds. Significant reactivity was observed at $1 \mathrm{~mol} \%$ catalyst loading.

## Chapter 10: Experimental

Reagents were obtained from Aldrich, Lancaster and Fluka chemical suppliers. Solvents and reagents were purified according to the procedures of Perrin, Armarego and Perrin ${ }^{160}$ Dichloromethane was dried by refluxing over, and distilling from calcium hydride. Ethanol was dried by refluxing over magnesium, followed by distillation. Toluene was dried over sodium wire for twenty-four hours prior to use. Anhydrous diethyl ether was obtained by distillation from sodium benzophenone ketyl.

All reactions using air/moisture sensitive reagents were performed in oven-dried or flamedried apparatus, under a nitrogen atmosphere. Catalytic runs were performed using a Radley's carousel, which consists of twelve test tubes with suba-seals and nitrogen inlets, a stirrer plate and a bath for heating. All reactions were followed and monitored by TLC, ${ }^{1} \mathrm{H}$ NMR, ${ }^{13} \mathrm{C}$ NMR and mass spectrometry as appropriate.

TLC analysis refers to analytical thin layer chromatography, using aluminium-backed plates coated with Merck Kieselgel $60 \mathrm{GF}_{254}$. Product spots were viewed either by the quenching of UV fluorescence, or by staining with a solution of $2 \%$ aqueous potassium permanganate. Chromatography refers to flash column chromatography using head pressure by means of compressed air according to the procedure of Still ${ }^{161}$ using Merck Kieselgel 60 H silica or Matrix silica 60.

Melting points were recorded using a Kofler Heated Stage Micro Melting Point Apparatus and are uncorrected.

Infra-red spectra were recorded in the range $4000-600 \mathrm{~cm}^{-1}$ using a Perkin-Elmer 1600 series FTIR instrument either as a thin film, a nujol mull or dissolved in stated solvent between sodium chloride plates. All absorptions are quoted in wave numbers $\left(\mathrm{cm}^{-1}\right)$.
${ }^{1} \mathrm{H}$ NMR spectra ( $\delta_{\mathrm{H}}$ ) were recorded using an Avance Bruker DPX 400 instrument (400 $\mathrm{MHz})$ or an Avance Bruker DPX $500(500 \mathrm{MHz})$, with ${ }^{13} \mathrm{C}$ NMR spectra $\left(\delta_{\mathrm{C}}\right)$ recorded at 100 MHz or 125 MHz respectively. Chemical shifts ( $\delta_{\mathrm{H}}$ and $\delta_{\mathrm{C}}$ ) were recorded in parts per million (ppm) from tetramethylsilane (or chloroform) and are corrected to 0.00 (TMS) and
$7.26\left(\mathrm{CHCl}_{3}\right)$ for ${ }^{1} \mathrm{H}$ NMR and $77.30\left(\mathrm{CHCl}_{3}\right)$, centre line, for ${ }^{13} \mathrm{C}$ NMR. The abbreviations $\mathrm{s}, \mathrm{d}, \mathrm{t}$, q, sept., m, bs and br, denote singlet, doublet, triplet, quartet, septet, multiplet, broad singlet and broadened resonances, respectively; all coupling constants were recorded in hertz ( Hz ).

Low resolution mass spectrometric data was determined using a Fisons VG Platform II Quadrapole instrument using atmospheric pressure chemical ionisation (APcI) unless otherwise stated. EI refers to electron ionisation and ES refers to electrospray. High resolution mass-spectrometric data was obtained courtesy of the EPSRC Mass Spectrometry Service at the University of Wales, Swansea, UK, using the ionisation methods specified. Calculated accurate masses are of the parent ion (exclusive of an electron, mass $=0.00055$ Da).

## Typical experimental procedure for catalytic runs

trans-Cinnamaldehyde $\mathbf{2 0}$ ( $252 \mathrm{mg}, 1.9 \mathrm{mmol}, 0.24 \mathrm{~mL}, 1.0 \mathrm{eq}$ ) was added to a solution of catalyst ( $10 \mathrm{~mol} \%, 0.19 \mathrm{mmol}$ ) in methanol $(2.0 \mathrm{~mL})$ at $25^{\circ} \mathrm{C}$ and the resulting mixture was stirred for 5 minutes to initiate iminium ion formation. Freshly cracked cyclopentadiene 19 ( $323 \mathrm{mg}, 4.9 \mathrm{mmol}, 0.38 \mathrm{~mL}, 2.5 \mathrm{eq}$ ) was added in a single aliquot and stirring was continued for 24 hours. The volatiles were removed under reduced pressure and the resulting organics were hydrolysed in a chloroform ( 2 mL ), water ( 1 mL ) trifluoroacetic acid ( 1 mL ) mixture over night. Saturated sodium hydrogen carbonate solution ( 18 mL ) was added to neutralise the solution and the aqueous phase was extracted with dichloromethane $(2 \times 20 \mathrm{~mL})$. The combined organics were washed with water $(10 \mathrm{~mL})$ and dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$ prior to the removal of the volatiles under reduced pressure. ${ }^{1} \mathrm{H}$ NMR of the crude reaction mixture was used to establish the conversion to the products and exo:endo ratios through the integration of aldehyde peaks at: $\delta_{\mathrm{H}}\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) 9.80$ (exo) 9.65 (cinnamaldehyde) 9.53 (endo). The products were then purified by flash column
chromatography eluting with (9:1) ethyl acetate/petroleum ether resulting in a mixture of the exo- and endo- isomers of 3-phenyl-bicyclo[2.2.1]hept-5-ene-2-carboxaldehyde 24 and 25 as a pale yellow oil. ${ }^{1} \mathrm{H}$ NMR, ${ }^{13} \mathrm{C}$ NMR and IR data were consistent with previously reported literature values; ${ }^{162} v_{\max }$ (liquid film) $/ \mathrm{cm}^{-1} 1718,1601$, 1497; exo-isomer $24{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\oint_{\mathrm{H}} 9.85(1 \mathrm{H}, \mathrm{d}, J=2.0, \mathrm{CHO}) 7.4-7.0(5 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}) 6.27(1 \mathrm{H}$, dd, $J=5.63 .6, \mathrm{C} \underline{H}=\mathrm{CH}) 6.01(1 \mathrm{H}, \mathrm{dd}, J=5.63 .6, \mathrm{CH}=\mathrm{CH}) 3.66(1 \mathrm{H}, \mathrm{dd}, J=5.03 .4$, CHPh) 3.25-3.05 ( $2 \mathrm{H}, \mathrm{m}, \mathrm{CHCH}_{2}$ ) 2.55-2.45 ( $1 \mathrm{H}, \mathrm{m}, \mathrm{CHCHO}$ ) 1.65-1.45 ( $2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}$ ); endo-isomer $25{ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}} 9.53(1 \mathrm{H}, \mathrm{d}, J=2.1, \mathrm{CHO}) 7.4-7.0(5 \mathrm{H}, \mathrm{m}$, Ar- $\underline{H}$ ) $6.36(1 \mathrm{H}, \mathrm{dd}, J=5.63 .6, \mathrm{CH}=\mathrm{CH}) 6.10(1 \mathrm{H}, \mathrm{dd}, J=5.63 .6, \mathrm{CH}=\mathrm{CH}) 3.26(1 \mathrm{H}, \mathrm{m}$, CHPh) $3.05\left(1 \mathrm{H}, \mathrm{m}, \mathrm{CHCH}_{2}\right) 3.01\left(1 \mathrm{H}, \mathrm{m}, \mathrm{CHCH}_{2}\right) 2.91(1 \mathrm{H}, \mathrm{m}, \mathrm{C} \underline{\mathrm{HCHO}}) 1.46-1.49(2 \mathrm{H}$, $\mathrm{m}, \mathrm{CH}_{2}$ ); $m / z(\mathrm{EI})[\mathrm{M}]^{+} 198(10 \%) 132$ (89) 131 (100) 103 (52) 77 (21) 66 (54).

## General Procedure 1

To a solution of $N, N^{\prime}$ dimethylhydrazine (1eq) in acetonitrile ( 40 mL ) was added ethyl glyoxylate $50 \% \mathrm{w} / \mathrm{w}$ solution in toluene ( 1 eq ) and acetic acid ( 0.2 mL ). The solution was stirred at ambient temperature overnight. Water ( 20 mL ) was added and the aqueous layer extracted with ethyl acetate ( $3 \times 30 \mathrm{~mL}$ ). The organics were dried over $\mathrm{MgSO}_{4}$, filtered and concentrated under reduced pressure to yield the crude imine as a pale yellow oil. The crude imine was analysed to determine reaction extent and was then dissolved in methanol and stirred at room temperature. To this was added sodium cyanoborohydride (1eq) followed by sufficient 2 M HCl solution to maintain a $\mathrm{pH} 3-4$ for a period of twenty minutes until a constant pH reading was obtained. A further equivalent of sodium cyanoborohydride was added and the procedure repeated to a total of three times. Once a constant pH was achieved after the third addition the reaction was allowed to stir at room temperature overnight. On reaction completion by TLC the mixture was quenched by adding sufficient 2 M HCl to maintain pH 1 for five minutes. To this was added $\mathrm{H}_{2} \mathrm{O}(20 \mathrm{~mL})$, ethyl acetate ( 30 mL ) and neutralised with $20 \%$ w/v $\mathrm{Na}_{2} \mathrm{CO}_{3}$ solution. The aqueous layer was extracted with ethyl acetate ( $3 \times 30 \mathrm{~mL}$ ). The organics were combined and dried over $\mathrm{MgSO}_{4}$ and the volatiles removed under reduced pressure.

The HCl salt was prepared by adding 5 eq of HCl (in MeOH ) to a solution of the free base in methanol with swirling for 10 minutes followed by removal of the volatiles under reduced pressure. The resulting solid was then washed with ether and dried under reduced pressure

## General Procedure 2

To a stirred solution of $N$-iso-propylidene- $N^{\prime}$-methyl-hydrazine $\mathbf{1 0 0}$ (1eq) and triethylamine (1eq) in dichloromethane ( 20 ml ) in at $0{ }^{\circ} \mathrm{C}$ was added the acid chloride (1eq) in dichloromethane ( 5 mL ) slowly over a period of five minutes, , the solution was then allowed to warm to room temperature and stirred overnight. Once the reaction appeared to be over by $\mathrm{TLC} \mathrm{H}_{2} \mathrm{O}(20 \mathrm{~mL})$ was added and the aqueous solution extracted with dichloromethane ( $3 \times 20 \mathrm{~mL}$ ). The combined organics were dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and the volatiles removed under reduced pressure to yield the crude product. The crude product was analysed to determine reaction extent and was then dissolved in methanol and stirred at room temperature. To this was added sodium cyanoborohydride ( 1 eq ) followed by sufficient 2 M HCl solution to maintain a $\mathrm{pH} 3-4$ for a period of twenty minutes until a constant pH reading was obtained. A further equivalent of sodium cyanoborohydride was added and the procedure repeated to a total of three times. Once a constant pH was achieved after the third addition the reaction was allowed to stir at room temperature overnight. On reaction completion by TLC the mixture was quenched by adding sufficient 2 M HCl to maintain pH 1 for five minutes. To this was added $\mathrm{H}_{2} \mathrm{O}(20 \mathrm{~mL})$, ethyl acetate ( 30 mL ) and neutralised with $20 \% \mathrm{w} / \mathrm{v} \mathrm{Na}_{2} \mathrm{CO}_{3}$ solution. The aqueous layer was extracted with ethyl acetate ( $3 \times 30 \mathrm{~mL}$ ). The organics were combined and dried over $\mathrm{MgSO}_{4}$ and the volatiles removed under reduced pressure.

The HCl salt was prepared by adding 5 eq of HCl (in MeOH ) to a solution of the free base in methanol with swirling for 10 minutes followed by removal of the volatiles under reduced pressure. The resulting solid was then washed with ether and dried under reduced pressure to yield the title compound as a colourless solid.

Preparation of ethyl 2-(2,2-dimethylhydrazinyl)acetate hydrochloride $\mathbf{7 4 .} \mathbf{H C l}^{163}$

The title compound was prepared using general procedure 1. The crude residue was purified using column chromatography eluting with (1:1) petroleum ether/ethyl acetate to give the free base ( $137 \mathrm{mg}, 2 \%$ ) as a colourless oil. ${ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}} 6.32(1 \mathrm{H}$, bs, $\mathrm{NH}), 4.14\left(2 \mathrm{H}, \mathrm{q}, J=7.2, \mathrm{CH}_{2} \mathrm{CH}_{3}\right), 3.50\left(2 \mathrm{H}, \mathrm{s}, \mathrm{NCH}_{2}\right), 2.40\left(6 \mathrm{H}, \mathrm{s}, \mathrm{NCH}_{3}\right), 1.21(3 \mathrm{H}, \mathrm{t}, J$ $\left.=7.5, \mathrm{CH}_{2} \mathrm{CH}_{3}\right)^{13} \mathrm{C}$ NMR $\left(100 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{C}} 169.4,62.0,51.4,47.6,14.0$.

The HCl salt was prepared using general procedure $1(93 \%) . \mathrm{mp} 71-73^{\circ} \mathrm{C}$.

## Preparation of ethyl 2-(methoxyamino)acetate hydrochloride 75.HCl

The title compound was prepared using general procedure 1. The resulting residue was purified by column chromatography eluting with (2:1) ethyl acetate/petroleum ether to afford the free base as a colourless oil ( $314 \mathrm{mg}, 5 \%$ ). ${ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}} 6.14$ $(1 \mathrm{H}, \mathrm{bs} \mathrm{NH}), 4.23\left(2 \mathrm{H}, \mathrm{q}, J=7.1, \mathrm{CH}_{2} \mathrm{CH}_{3}\right), 3.62\left(2 \mathrm{H}, \mathrm{bd}, J=5.6, \mathrm{NHCH}_{2}\right), 3.54(3 \mathrm{H}, \mathrm{s}$ $\left.\mathrm{OCH}_{3}\right), 1.27\left(3 \mathrm{H}, \mathrm{t}, J=7.1, \mathrm{CH}_{2} \mathrm{CH}_{3}\right)$.

The HCl salt was prepared using general procedure $1 .(90 \%) . \mathrm{mp} 80-82^{\circ} \mathrm{C}$.

## Preparation of 76.HCl

The title compound was prepared using general procedure 1. The resulting solid was purified by column chromatography eluting with (3:1) dichloromethane/diethyl ether to yield the free base ( $1.42 \mathrm{~g}, 26 \%$ ) as a colourless solid. $\mathrm{mp} 88-89{ }^{\circ} \mathrm{C} ;{ }^{1} \mathrm{H}$ NMR $(400 \mathrm{MHz}$, $\left.\mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}} 6.48(1 \mathrm{H}, \mathrm{bs}, \mathrm{NH}), 4.17-4.07\left(5 \mathrm{H}, \mathrm{m}, \mathrm{N} \underline{\mathrm{H}}, \mathrm{CH}_{2} \mathrm{CH}_{3}\right), 3.59\left(\mathrm{H}, \mathrm{d}, \mathrm{J}=4, \mathrm{NCH}_{2}\right)$,
1.24-1.18 ( $6 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2} \mathrm{CH}_{3}$ ); ${ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{C}} 171.3(\mathrm{C}), 156.9$ (C), 61.5 $\left(\mathrm{CH}_{2}\right), 61.2\left(\mathrm{CH}_{2}\right), 52.8\left(\mathrm{CH}_{2}\right), 14.6\left(\mathrm{CH}_{3}\right), 14.2\left(\mathrm{CH}_{3}\right)$;

The HCl salt was prepared using general procedure $1 .(95 \%) . \mathrm{mp} 115-118^{\circ} \mathrm{C}$.

## Preparation of $\mathbf{7 7 . H C l}$

The title compound was prepared using general procedure 1. The resulting residue was purified by column chromatography eluting with (4:1) dichloromethane/diethyl ether to yield the free base $(6.86 \mathrm{~g}, 78 \%)$ as a colourless oil. $v_{\max }$ (neat) $/ \mathrm{cm}^{-1} 3320,2937,2908$, $2882,1728,1530,1554 ;{ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}} 6.48(1 \mathrm{H}, \mathrm{bs}, \mathrm{NH}), 4.25-4.14(5 \mathrm{H}$, $\left.\mathrm{m}, \mathrm{NH}, \mathrm{CH}_{2} \mathrm{CH}_{3}\right), 3.76-3.75\left(1 \mathrm{H}, \mathrm{m}, \mathrm{NHCHCH}_{3}\right), 1.36-1.25\left(9 \mathrm{H}, \mathrm{m}, \mathrm{CHCH}_{3}, \mathrm{CH}_{2} \mathrm{CH}_{3}\right) ;{ }^{13} \mathrm{C}$ NMR ( $125 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{C}} 173.4(\mathrm{C}), 157.1(\mathrm{C}), 61.5(\mathrm{CH} 2), 61.2(\mathrm{CH} 2), 58.4(\mathrm{CH}), 15.9$ $\left(\mathrm{CH}_{3}\right), 14.6\left(\mathrm{CH}_{3}\right), 14.21\left(\mathrm{CH}_{3}\right)$.

The HCl salt was prepared using general procedure $1 .(98 \%) . \mathrm{mp} 138^{\circ} \mathrm{C}$.

## Preparation of 85.HCl

The title compound was prepared using general procedure 1 . The resulting mixture was then purified by column chromatography eluting with (1:1) petroleum ether/ ethyl acetate to yield the free base $(1.31 \mathrm{~g}, 38 \%)$ as a colourless oil. $v_{\max }\left(\mathrm{CHCl}_{3}\right) / \mathrm{cm}^{-1} 3384,2959,1753,1538$, $1455,1277,1152 ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{H}} 6.78(1 \mathrm{H}, \mathrm{bs}, \mathrm{NH}), 4.31(1 \mathrm{H}, \mathrm{bs}, \mathrm{NH})$, 3.84-3.71 $\left(7 \mathrm{H}, \mathrm{m}, \mathrm{CHCH}_{3}, \mathrm{OCH}_{3}\right), 1.36\left(3 \mathrm{H}, \mathrm{d}, J=7.2, \mathrm{CHCH}_{3}\right) ;{ }^{13} \mathrm{C}$ NMR ( 100 MHz , $\left.\mathrm{CDCl}_{3}\right) \delta_{\mathrm{C}} 174.3(\mathrm{C}), 157.6(\mathrm{C}), 58.2(\mathrm{CH}), 52.4\left(\mathrm{CH}_{3}\right), 52,0\left(\mathrm{CH}_{3}\right), 15.8\left(\mathrm{CH}_{3}\right) ; m / z(\mathrm{APCI})$ $(\mathrm{M}+\mathrm{H})$ 177; HRMS (ES) (found $177.0871[\mathrm{M}+\mathrm{H}]^{+} ; \mathrm{C}_{6} \mathrm{H}_{13} \mathrm{~N}_{2} \mathrm{O}_{4}$ requires 177.0870).

The HCl salt was prepared using general procedure $1 .(92 \%) . \mathrm{mp} 133-134^{\circ} \mathrm{C}$.

## 2-Methyl-1-(propan-2-ylidene)hydrazine 100

Methyl hydrazine ( $13.6 \mathrm{~g}, 295 \mathrm{mmol}, 15.7 \mathrm{~mL}$ ) was added drop wise to acetone ( $23.7 \mathrm{~g}, 409$ $\mathrm{mmol}, 30 \mathrm{~mL}$ ) maintaining the reaction temperature below $35^{\circ} \mathrm{C}$. The solution was stirred for 1 hour after which the top layer was removed and allowed to stand over potassium hydroxide ( 5 g ) for a further 1 hour. The upper liquid was decanted from the lower aqueous phase and allowed to stand over two successive portions of potassium hydroxide $(2 \times 2.5 \mathrm{~g})$ for 30 minutes each. Purification was by distillation ( $1 \mathrm{~atm} ., 110^{\circ} \mathrm{C}$ ) [lit. ${ }^{118} \mathrm{~b} . \mathrm{pt} .116-118$ ${ }^{\circ} \mathrm{C}$ ] under nitrogen affording the title compound as a colourless oil ( $17.85 \mathrm{~g}, 70 \%$ ); $v_{\max }$ (liquid film) $/ \mathrm{cm}^{-1} 3394,3262,2911,1711,1631 ;{ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}} 4.28(1 \mathrm{H}$, s br, NH ) $2.76\left(3 \mathrm{H}, \mathrm{s}, \mathrm{NHCH}_{3}\right) 1.88\left(3 \mathrm{H}, \mathrm{s}, \mathrm{N}=\mathrm{CCH} \underline{H}_{3}\right.$ trans $) 1.68\left(3 \mathrm{H}, \mathrm{s}, \mathrm{N}=\mathrm{C}-\mathrm{CH}_{3}\right.$ cis $){ }^{13} \mathrm{C}$ NMR ( $\left.100 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{C}} 146.4(\mathrm{C}) 37.9\left(\mathrm{CH}_{3}\right) 25.0\left(\mathrm{CH}_{3}\right) 15.5\left(\mathrm{CH}_{3}\right) ; \mathrm{m} / \mathrm{z}(\mathrm{APcI})$ $[\mathrm{M}+\mathrm{H}]^{+} 87(100 \%)$; $\mathrm{HRMS}(\mathrm{EI})$ (found $86.0841\left[\mathrm{M}^{+} ; \mathrm{C}_{4} \mathrm{H}_{10} \mathrm{~N}_{2}\right.$ requires 86.0838 ).

## Preparation of 1-isopropyl-2-methyl-4-phenylsemicarbazide 93

To a stirred solution of $N$-iso-propylidene- $N^{\prime}$-methyl-hydrazine $100(1.00 \mathrm{~g}, 11.6 \mathrm{mmol}$, $1.16 \mathrm{~mL}) 36$ in dichloromethane $(20 \mathrm{~mL})$ at $0^{\circ} \mathrm{C}$ was added phenyl isocyanate $(1.38 \mathrm{~g}, 11.6$ $\mathrm{mmol}, 1.26 \mathrm{~mL}$ ) in dichloromethane ( 5 mL ) slowly over a period of five minutes, the solution was then allowed to warm to room temperature and stirred overnight. Once the reaction appeared to be over by $\mathrm{TLC} \mathrm{H}_{2} \mathrm{O}(20 \mathrm{~mL})$ was added and the aqueous solution extracted with dichloromethane ( $3 \times 20 \mathrm{~mL}$ ). The combined organics were dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and the volatiles removed under reduced pressure to yield the crude product. The crude product was analysed to determine reaction extent and was then dissolved in methanol (20 mL ) and stirred at room temperature. To this was added sodium cyanoborohydride ( 0.72 g 11.6 mmol ) followed by sufficient 2 M HCl solution to maintain a $\mathrm{pH} 3-4$ for a period of twenty minutes until a constant pH reading was obtained. A further equivalent of sodium
cyanoborohydride was added and the procedure repeated to a total of three times. Once a constant pH was achieved after the third addition the reaction was allowed to stir at room temperature overnight. On reaction completion by TLC the mixture was quenched by adding sufficient 2 M HCl to maintain pH 1 for five minutes. To this was added $\mathrm{H}_{2} \mathrm{O}$ ( 20 mL ), ethyl acetate ( 30 mL ) and neutralised with $20 \% \mathrm{w} / \mathrm{v} \mathrm{Na}_{2} \mathrm{CO}_{3}$ solution. The aqueous layer was extracted with ethyl acetate ( $3 \times 30 \mathrm{~mL}$ ).The organics combined and dried over $\mathrm{MgSO}_{4}$ and the volatiles removed under reduced pressure. The crude product was purified by column chromatography eluting with (2:1) petroleum ether/ethyl acetate resulting in the free base ( $1.97 \mathrm{~g}, 82 \%$ ) as a colourless solid. $\mathrm{mp} 80-81^{\circ} \mathrm{C}$; $v_{\text {max }}\left(\mathrm{CDCl}_{3}\right) / \mathrm{cm}^{-1} 3366,2975$, $2359,1792,1666,1533 ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{H}} 8.59(1 \mathrm{H}, \mathrm{bs}, \mathrm{NH}), 7.45$ ( $2 \mathrm{H}, \mathrm{d}, \mathrm{J}$ $=8.6, \operatorname{Ar}-\underline{H}), 7.29(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\mathrm{H}), 6.94(1 \mathrm{H}, \mathrm{t}, J=7.4, \mathrm{Ar}-\mathrm{H}) 3.36-3.27(2 \mathrm{H}, \mathrm{m}, \mathrm{NH}, \mathrm{CH})$, $3.16\left(3 \mathrm{H}, \mathrm{s}, \mathrm{NCH}_{3}\right), 1.11\left(6 \mathrm{H}, \mathrm{d}, \mathrm{J}=6.2, \mathrm{CH}_{3}\right) ;{ }^{13} \mathrm{C} \mathrm{NMR}\left(100 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{C}} 156.8(\mathrm{C})$, $139.2(\mathrm{C}), 128.9(\mathrm{CH}), 122.3(\mathrm{C}), 118.6(\mathrm{CH}), 47.1(\mathrm{CH}), 32.2\left(\mathrm{CH}_{3}\right), 20.5\left(\mathrm{CH}_{3}\right) ; m / z(\mathrm{ES})$ $[\mathrm{M}+\mathrm{H}]^{+} ; 208$ (100\%) HRMS (ES) (found $208.1446[\mathrm{M}+\mathrm{H}]^{+} ; \mathrm{C}_{11} \mathrm{H}_{17} \mathrm{~N}_{3} \mathrm{O}$ requires 208.1444).

The HCl salt was prepared by adding 5 eq of 3.8 M HCl (in MeOH ) to a solution of the free base in methanol with swirling for 10 minutes followed by removal of the volatiles under reduced pressure. The resulting solid was then washed with ether and dried under reduced pressure to yield the title compound as a colourless solid (96\%). mp 149-150 ${ }^{\circ} \mathrm{C}$.

## Preparation of 4-(dimethylamino)- $N^{\prime}$-isopropyl- $N$-methylbenzohydrazide 95

The title compound was prepared using general procedure 2 . The crude product was purified by column chromatography eluting with ( $2: 1$ ) petroleum ether/ethyl acetate resulting in the free base ( $1.29 \mathrm{~g}, 63 \%$ ) as an off white solid. $\mathrm{mp} 69-70^{\circ} \mathrm{C}$; $v_{\max }\left(\mathrm{CDCl}_{3}\right) / \mathrm{cm}^{-1} 3685,3262$, $3153,2969,2901,2812,2358,1792,1608,1526,1469,1428,{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{H}} 7.45(2 \mathrm{H}, \mathrm{d}, J=8.7, \mathrm{Ar}-\underline{\mathrm{H}}), 6.60(2 \mathrm{H}, \mathrm{d}, J=8.9, \mathrm{Ar}-\underline{\mathrm{H}}), 3.18\left(4 \mathrm{H}, \mathrm{m}, \mathrm{C} \underline{\mathrm{H}}, \mathrm{NC} \underline{H}_{3}\right), 2.94$ ( $6 \mathrm{H}, \mathrm{S}, \mathrm{NCH}_{3}$ ), $0.86\left(6 \mathrm{H}, \mathrm{d}, J=6.2, \mathrm{CH}_{3}\right.$ ); ${ }^{13} \mathrm{C}$ NMR ( $62.5 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{C}} 171.9$ (C),
$\qquad$ TJ K Gibbs- PhD Thesis 2008
$151.7(\mathrm{C}), 130.0(\mathrm{CH}), 122.0(\mathrm{C}), 110.9(\mathrm{CH}), 49.6\left(\mathrm{CH}_{3}\right), 40.2\left(\mathrm{CH}_{3}\right), 39.8(\mathrm{CH}), 20.9$ $\left(\mathrm{CH}_{3}\right) ; m / z(\mathrm{ES})[\mathrm{M}+\mathrm{H}]^{+} ; 236$ (100\%) HRMS (ES) (found $236.1757[\mathrm{M}+\mathrm{H}]^{+} ; \mathrm{C}_{13} \mathrm{H}_{21} \mathrm{~N}_{3} \mathrm{O}$ requires 236.1759 ).

The HCl salt was prepared using general procedure 2 ( $89 \%$ ). $\mathrm{mp} 88^{\circ} \mathrm{C}$.

## Preparation of $N^{\prime}$-isopropyl- $N$-methyl-4-nitrobenzohydrazide 99

The title compound was prepared using general procedure 2. The crude product was purified by column chromatography eluting with (1:1) petroleum ether/ethyl acetate resulting in the free base ( $1.18 \mathrm{~g}, 33 \%$ ) as an off white solid. $\mathrm{mp} 58^{\circ} \mathrm{C} ; \mathrm{v}_{\max }\left(\mathrm{CDCl}_{3}\right) / \mathrm{cm}^{-1} 3434,2968$, 2106, 1636, 1520; ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{DMSO}$ ) $\delta_{\mathrm{H}} 8.19$ ( $2 \mathrm{H}, \mathrm{d}, J=8.8, \mathrm{Ar}-\underline{\mathrm{H}}$ ), 7.67 ( $2 \mathrm{H}, \mathrm{d}$, $J=8.4, \mathrm{Ar}-\underline{\mathrm{H}}), 5.04(1 \mathrm{H}, \mathrm{s}, \mathrm{N} \underline{\mathrm{H}}), 3.14-3.11\left(4 \mathrm{H}, \mathrm{m}, \mathrm{CH}, \mathrm{NCH}_{3}\right), 0.66\left(6 \mathrm{H}, \mathrm{d}, J=6.0, \mathrm{CH}_{3}\right)$; ${ }^{13} \mathrm{C}$ NMR $\delta_{\mathrm{C}}(62.5 \mathrm{MHz}, \mathrm{DMSO}) 170.2$ (C), 147.6 (C), $144.4(\mathrm{C}), 130.1(\mathrm{CH}), 123.0(\mathrm{CH})$, $46.7\left(\mathrm{CH}_{3}\right), 33.0(\mathrm{CH}), 20.5\left(\mathrm{CH}_{3}\right) ; m / z(\mathrm{ES})[\mathrm{M}+\mathrm{H}]^{+} ; 238$ (100\%) HRMS (ES) (found $238.1032[\mathrm{M}+\mathrm{H}]^{+} ; \mathrm{C}_{10} \mathrm{H}_{15} \mathrm{~N}_{3} \mathrm{O}_{3}$ requires 238.1030).

The HCl salt was prepared using general procedure 2. (93\%). $\mathrm{mp} 144^{\circ} \mathrm{C}$.

## Preparation of $N^{\prime}$-isopropyl-4-methoxy- $N$-methylbenzohydrazide 77

The title compound was prepared using general procedure 2 The crude product was purified by column chromatography eluting with (1:1) petroleum ether/ethyl acetate resulting in the free base ( $1.32 \mathrm{~g}, 51 \%$ ) as a colourless solid. $\mathrm{mp} 42-44^{\circ} \mathrm{C}$; $v_{\max }\left(\mathrm{CDCl}_{3}\right) / \mathrm{cm}^{-1} 3436,3269$, 3153, 2968, 2933, 2838, 1610, 1512, 1465; ${ }^{1} \mathrm{H}$ NMR ( $250 \mathrm{MHz}, 35^{\circ} \mathrm{C}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{H}} 7.51$
$(2 \mathrm{H}, \mathrm{d}, J=8.5, \mathrm{Ar}-\underline{\mathrm{H}}), 6.90(2 \mathrm{H}, \mathrm{d}, J=8.8, \mathrm{Ar}-\underline{\mathrm{H}}), 3.81\left(3 \mathrm{H}, \mathrm{s}, \mathrm{OCH}_{3}\right), 3.27-3.15(4 \mathrm{H}, \mathrm{m}$, $\left.\mathrm{CH}, \mathrm{NCH}_{3}\right), 1.06\left(6 \mathrm{H}, \mathrm{d}, \mathrm{J}=6.0, \mathrm{CH}_{3}\right) ;{ }^{13} \mathrm{C} \mathrm{NMR}\left(100 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{C}} 171.1(\mathrm{C}), 161.1$ (C), $129.7(\mathrm{CH}), 127.6(\mathrm{CH}), 113.4(\mathrm{C}), 55.3\left(\mathrm{CH}_{3}\right), 49.6\left(\mathrm{CH}_{3}\right), 41.7(\mathrm{CH}), 20.8\left(\mathrm{CH}_{3}\right) ; \mathrm{m} / \mathrm{z}$ (ES) $[\mathrm{M}+\mathrm{H}]^{+} ; 223(100 \%)$ HRMS (ES) (found $223.1441[\mathrm{M}+\mathrm{H}]^{+} ; \mathrm{C}_{12} \mathrm{H}_{18} \mathrm{~N}_{2} \mathrm{O}_{2}$ requires 223.1441).

The HCl salt was prepared using general procedure $2(91 \%) . \mathrm{mp} 130-133^{\circ} \mathrm{C}$.

## Preparation of 4-chloro- $N^{\prime}$-isopropyl- $N$-methylbenzohydrazide 97

The title compound was prepared using general procedure 2 The crude product was purified by column chromatography eluting with (5:1) ethyl acetate/petroleum ether resulting in the title compound ( $1.13 \mathrm{~g}, 43 \%$ ) as a colourless oil. Analysis of this compound clearly indicated that it posses many rotational states in solution. $\mathrm{v}_{\text {max }}\left(\mathrm{CDCl}_{3}\right) / \mathrm{cm}^{-1} 3420,2105$, 1639 ; ${ }^{1} \mathrm{H}$ NMR ( $500 \mathrm{MHz}, \mathrm{DMSO}$ ) $\delta_{\mathrm{H}} 7.65-7.50(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}), 7.41(2 \mathrm{H}, \mathrm{bs}, \mathrm{Ar}-\underline{\mathrm{H}}), 4.98$ ( $1 \mathrm{H}, \mathrm{bs}, \mathrm{NH}$ ), $3.26-3.11\left(4 \mathrm{H}, \mathrm{m}, \mathrm{C} \underline{H}, \mathrm{NCH}_{3}\right), 0.77\left(6 \mathrm{H}, \mathrm{bs}, \mathrm{CH}_{3}\right) ;{ }^{13} \mathrm{C}$ NMR ( 125 MHz , DMSO) $\delta_{\mathrm{C}} 164.2(\mathrm{C}), 133.7(\mathrm{C}), 130.5(\mathrm{CH}), 129.1(\mathrm{CH}), 129.0(\mathrm{CH}), 127.3(\mathrm{CH}), 20.2$ $\left(\mathrm{CH}_{3}\right)$, other carbons were not observed; $m / z(\mathrm{ES})[\mathrm{M}+\mathrm{H}]^{+} ; 227(100 \%)$ HRMS (ES) (found $227.0946[\mathrm{M}+\mathrm{H}]^{+} ; \mathrm{C}_{11} \mathrm{H}_{17} \mathrm{~N}_{3} \mathrm{O}$ requires 227.0946).

The HCl salt was prepared in situ within the reaction flask of the catalytic run by adding 1 eq of HCl in methanol. The volume of methanol as a solvent was then adjusted to maintain the correct reaction concentration.

Preparation of 2,3,4,5,6-pentafluoro- $N^{\prime}$-isopropyl- $N$-methylbenzohydrazide 96

To a stirred solution of $N$-iso-propylidene- $N^{\prime}$-methyl-hydrazine $100(1 \mathrm{~g}, 11.6 \mathrm{mmol}, 1.16$ mL ) and triethylamine ( $1.17 \mathrm{~g}, 11.6 \mathrm{mmol}, 1.61 \mathrm{~mL}$ ) in dichloromethane ( 20 mL ) at $0{ }^{\circ} \mathrm{C}$ was added 4 dimethylamino benzoyl chloride $(2.67 \mathrm{~g}, 11.6 \mathrm{mmol})$ in dichloromethane ( 5 mL ) slowly over a period of five minutes, the solution was then allowed to warm to room temperature and stirred overnight. Once the reaction appeared to be over by TLC $\mathrm{H}_{2} \mathrm{O}(20$ mL ) was added and the aqueous solution extracted with dichloromethane ( $3 \times 20 \mathrm{~mL}$ ). The combined organics were dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and the volatiles removed under reduced pressure to yield the crude product. The crude product was analysed to determine the extent of reaction and was then dissolved in a mixture of ethanol ( 12 mL ) and acetic acid ( 6 mL ). To this solution was added Platinium(IV) oxide ( $131 \mathrm{mg}, 0.58 \mathrm{mmol}, 5 \mathrm{~mol} \%$ ) and stirred at room temperature. The flask was then evacuated and back filled with an $\mathrm{H}_{2}$ for a total of five times and allowed to stir at room temperature under an atmosphere of $\mathrm{H}_{2}$ for 18 hrs . The reaction mixture was then filtered through celite ${ }^{\circledR}$ and $\mathrm{H}_{2} \mathrm{O}(10 \mathrm{~mL})$ was added to the filtrate. The aqueous layer was then extracted with $\mathrm{CHCl}_{3}(3 \times 20 \mathrm{~mL})$, the organics combined, dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and the volatiles removed under reduced pressure. The crude product was purified by column chromatography eluting with (4:1) petroleum ether/ethyl acetate resulting in the free base ( $2.59 \mathrm{~g}, 79 \%$ ) as a pale pink solid. $\mathrm{mp} 77-77{ }^{\circ} \mathrm{C}$; $v_{\text {max }}$ $\left(\mathrm{CDCl}_{3}\right) / \mathrm{cm}^{-1} 3423,2973,2933,1654,1500 ;{ }^{1} \mathrm{H}$ NMR $(400 \mathrm{MHz}, \mathrm{DMSO}) \delta_{\mathrm{H}} 5.49(1 \mathrm{H}, \mathrm{bs}$, $\mathrm{NH}), 3.21-3.14\left(4 \mathrm{H}, \mathrm{m}, \mathrm{CH}, \mathrm{NCH}_{3}\right), 0.73\left(6 \mathrm{H}, \mathrm{d}, J=6.0, \mathrm{CH}_{3}\right) ;{ }^{13} \mathrm{C}$ NMR ( 62.5 MHz , DMSO) $\delta_{C} 160.2(\mathrm{C}), 45.6\left(\mathrm{CH}_{3}\right), 31.8(\mathrm{CH}), 19.6\left(\mathrm{CH}_{3}\right)$ other carbons were not observed; $m / z$ (ES) $[\mathrm{M}+\mathrm{H}]^{+} ; 283 ;$ HRMS (ES) (found $[\mathrm{M}+\mathrm{H}]^{+} ; 283.0862 \mathrm{C}_{11} \mathrm{H}_{11} \mathrm{~F}_{5} \mathrm{~N}_{2} \mathrm{O}$ requires 283.0864).

The HCl salt was prepared by adding 5 eq of HCl (in MeOH ) to a solution of the free base in methanol with swirling for 10 minutes followed by removal of the volatiles under reduced pressure. The resulting solid was then washed with ether and dried under reduced pressure to yield the title compound as a colourless solid (93\%). $\mathrm{mp} 111^{\circ} \mathrm{C}$.

## $N$-Methyl- $N$ '-iso-propyl benzoic hydrazide hydrochloride 90

The title compound 90 was prepared using general procedure 2 affording the product ( 150 $\mathrm{mg}, 11 \%$ ) as a colourless solid; $\mathrm{mp} 145-146^{\circ} \mathrm{C}$; $\mathrm{v}_{\max }($ nujol $) / \mathrm{cm}^{-1} 3408,2923,1638,1460$, 1377, 1333, 1122, 1077; ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{H}} 7.51(2 \mathrm{H}, \mathrm{d}, J=8.0, \mathrm{Ar}-\underline{\mathrm{H}})$, 7.49 $(1 \mathrm{H}, \mathrm{t}, J=7.1, \mathrm{Ar}-\underline{\mathrm{H}}), 7.42(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}), 3.94\left(1 \mathrm{H}\right.$, sept., $\left.J=6.6 \mathrm{NC} \underline{H}\left(\mathrm{CH}_{3}\right)_{2}\right), 3.61(3 \mathrm{H}, \mathrm{s}$, $\left.\mathrm{NCH}_{3}\right), 1.51\left(6 \mathrm{H}, \mathrm{d}, J=6.6, \mathrm{NCH}\left(\mathrm{CH}_{2}\right)_{3}\right) ;{ }^{13} \mathrm{C}$ NMR $\left(100 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{C}} 170.8(\mathrm{C}), 132.3$ (C), $130.7(\mathrm{CH}), 128.9(\mathrm{CH}), 128.2(\mathrm{CH}), 53.7\left(\mathrm{CH}_{3}\right), 38.6(\mathrm{CH}), 18.0\left(\mathrm{CH}_{3}\right) ; m / z(\mathrm{ES})$ $[\mathrm{M}+\mathrm{H}-\mathrm{HCl}]^{+} 193$ (100\%); HRMS (ES) (found $193.1336[\mathrm{M}+\mathrm{H}-\mathrm{HCl}]^{+} ; \mathrm{C}_{11} \mathrm{H}_{17} \mathrm{~N}_{2} \mathrm{O}$ requires 193.1335).

## $N^{\prime}$-(Propan-2-ylidene)benzoic hydrazide 103

Benzoic hydrazide $102(5.00 \mathrm{~g}, 36.7 \mathrm{mmol})$ was stirred in an excess of acetone ( $22 \mathrm{~mL}, 0.3$ mmol ), containing acetic acid ( $40 \mu \mathrm{~L}, 0.7 \mathrm{mmol}$ ), for 48 hours at ambient temperature. Water ( 30 mL ) was added and the reaction mixture was extracted with dichloromethane $(3 \times 30 \mathrm{~mL})$. The combined organic extracts were dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$ and reduced in vacuo to afford the title compound $(5.57 \mathrm{~g}, 86 \%)$ as a colourless solid; mp (petrol/ether) $141-143{ }^{\circ} \mathrm{C}$ [lit. ${ }^{121} \mathrm{mp} 142-143{ }^{\circ} \mathrm{C}$ ]; $v_{\text {max }}$ (nujol)/ $\mathrm{cm}^{-1} 3221,1655,1578,1578,1531,1490 ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{H}} 8.70(1 \mathrm{H}, \mathrm{s}, \mathrm{NH}), 7.79(2 \mathrm{H}, \mathrm{d}, J=7.1, \mathrm{Ar}-\underline{\mathrm{H}}), 7.52(1 \mathrm{H}, \mathrm{t}, J=7.1, \mathrm{Ar}-$ $\underline{\mathrm{H}}), 7.44(2 \mathrm{H}, \mathrm{t}, J=7.1, \mathrm{Ar}-\underline{\mathrm{H}}), 2.15\left(3 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{3}\right), 1.97\left(3 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{3}\right) ;{ }^{13} \mathrm{C}$ NMR ( 100 MHz , $\left.\mathrm{CDCl}_{3}\right) \delta_{\mathrm{C}} 164.6(\mathrm{C}), 156.9(\mathrm{C}), 134.1(\mathrm{C}), 132.1(\mathrm{CH}), 129.0(\mathrm{CH}), 127.6(\mathrm{CH}), 26.0$ $\left(\mathrm{CH}_{3}\right), 17.3\left(\mathrm{CH}_{3}\right) ; \mathrm{m} / \mathrm{z}(\mathrm{EI})[\mathrm{M}]^{+} 176(8 \%), 161(50), 105$ (100); HRMS (EI) (found $176.0950[\mathrm{M}]^{+} ; \mathrm{C}_{10} \mathrm{H}_{12} \mathrm{~N}_{2} \mathrm{O}$ requires 176.0950).
$N^{\prime}$-iso-Propylbenzoic hydrazide 91

Platinum(IV) oxide ( $68 \mathrm{mg}, 0.3 \mathrm{mmol}$ ) was placed in a nitrogen flushed flask with ethanol $(12 \mathrm{~mL})$ and acetic acid ( 6 mL ). $N^{\prime}$-(Propan-2-ylidene) benzoic hydrazide 103 ( $2.50 \mathrm{~g}, 14.2$ mmol ) was added, the flask was charged with hydrogen and stirred for 48 hours at ambient temperature. The reaction mixture was filtered over Celite and the filtrate was neutralised with saturated sodium bicarbonate solution $(180 \mathrm{~mL})$. The volatiles were removed under reduced pressure and the aqueous phase was extracted with diethyl ether ( $5 x 50 \mathrm{~mL}$ ). The combined organic extracts were washed with brine ( 30 mL ), dried $\left(\mathrm{MgSO}_{4}\right)$ and the volatiles were removed under reduced pressure to give the title compound ( $2.18 \mathrm{~g}, 86 \%$ ) as a colourless powder; mp $110-112{ }^{\circ} \mathrm{C}$; $\mathrm{v}_{\text {max }}$ (nujol)/ $/ \mathrm{cm}^{-1} 3289,1640,1537,725,693 ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{H}} 7.70(1 \mathrm{H}, \mathrm{s}, \mathrm{NH}), 7.69(2 \mathrm{H}, \mathrm{d}, J=7.7, \mathrm{Ar}-\underline{\mathrm{H}}), 7.46(1 \mathrm{H}, \mathrm{t}, J=7.7, \mathrm{Ar}-$ $\underline{\mathrm{H}}), 7.38(2 \mathrm{H}, \mathrm{t}, J=7.7, \mathrm{Ar}-\underline{\mathrm{H}}), 4.81(1 \mathrm{H}, \mathrm{s}, \mathrm{NH}), 3.18\left(1 \mathrm{H}\right.$, sept., $\left.J=6.2, \mathrm{NC} \underline{\mathrm{H}}\left(\mathrm{CH}_{3}\right)_{2}\right), 1.05$ ( $\left.6 \mathrm{H}, \mathrm{d}, J=6.2, \mathrm{NCH}\left(\mathrm{CH}_{3}\right)_{2}\right) ;{ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{C}} 167.5$ (C), 132.9 (C), 131.9 $(\mathrm{CH}), 128.7(\mathrm{CH}), 126.9(\mathrm{CH}), 51.4(\mathrm{CH}), 20.9\left(\mathrm{CH}_{3}\right) ; ~ m / z(\mathrm{EI})[\mathrm{M}]^{+} 178(3 \%), 163(9), 122$ (13), 105 (100); HRMS (EI) (found $178.1105[\mathrm{M}]^{+} ; \mathrm{C}_{10} \mathrm{H}_{14} \mathrm{~N}_{2} \mathrm{O}$ requires 178.1106).

## Preparation of 3-naphthalen-2-yl-propenal

Compound 117 was prepared in accordance of the procedure of Cacchi. ${ }^{164}$ To a stirred solution of 2 bromonapthalene ( $1.04 \mathrm{~g}, 5 \mathrm{mmol}$ ) in dry DMF ( 20 mL ) was added acrolein diethylacetal $(1.95 \mathrm{~g}, 15 \mathrm{mmol}, 2.28 \mathrm{~mL}),{ }^{\mathrm{n}} \mathrm{Bu}_{4} \mathrm{NOAc}(3.02 \mathrm{~g}, 10 \mathrm{mmol}), \mathrm{K}_{2} \mathrm{CO}_{3}(1.04 \mathrm{~g}$, $10 \mathrm{mmol}), \mathrm{KCl}(0.37 \mathrm{~g}, 5 \mathrm{mmol})$, and $\mathrm{Pd}(\mathrm{OAc})_{2}(0.03 \mathrm{~g}, 15 \mathrm{mmol})$. The mixture was stirred for 16 h at $90^{\circ} \mathrm{C}$. The solution was allowed to cool and $2 \mathrm{M} \mathrm{HCl}(5 \mathrm{~mL})$ was added slowly and the reaction stirred at room temperature for 10 min to allow hydrolysis of the acetal. The reaction was then diluted with ether and washed with water. The organic layer was then dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and concentrated in vacuo. The crude product was purified by column
chromatography (9:1) petroleum ether/ethyl acetate to yield the title compound ( 0.62 g , $68 \%$ ) as off white platy crystals; mp $125{ }^{\circ} \mathrm{C}, ;{ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}} 9.77(1 \mathrm{H}, \mathrm{d}, J$ $=7.7), 7.97-7.55(8 \mathrm{H}, \mathrm{m}), 6.83(1 \mathrm{H}, \mathrm{dd}, J=15.9,7.7) ;{ }^{13} \mathrm{C}\left(125 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{C}} 193.8$, 152.8, 134.7, 133.3, 131.6, 130.8, 129.0, 128.9, 128.7, 127.9, 127.1, 123.6; m/z (APCI) 183 $(\mathrm{M}+\mathrm{H}) ;$ HRMS (ES) (found $183.0804[\mathrm{M}+\mathrm{H}]^{+} ; \mathrm{C}_{13} \mathrm{H}_{10} \mathrm{O}$ requires 183.0804).

## Preparation of (E)-3-(3-(trifluoromethyl)phenyl)acrylaldehyde 118

Compound 118 was prepared in accordance of the procedure of Cacchi. ${ }^{164}$ To a stirred solution of 3-bromo benzotrifluoride ( $1.13 \mathrm{~g}, 5 \mathrm{mmol}, 0.70 \mathrm{~mL}$ ) in dry DMF ( 20 mL ) was added acrolein diethylacetal ( $1.95 \mathrm{~g}, 15 \mathrm{mmol}, 2.28 \mathrm{ml}$ ), ${ }^{\mathrm{n}} \mathrm{Bu}_{4} \mathrm{NOAc}(3.02 \mathrm{~g}, 10 \mathrm{mmol})$, $\mathrm{K}_{2} \mathrm{CO}_{3}(1.04 \mathrm{~g}, 10 \mathrm{mmol}), \mathrm{KCl}(0.37 \mathrm{~g}, 5 \mathrm{mmol})$, and $\mathrm{Pd}(\mathrm{OAc})_{2}(0.03 \mathrm{~g} .15 \mathrm{mmol})$. The mixture was stirred for 3 h at $90^{\circ} \mathrm{C}$. The solution was allowed to cool and $2 \mathrm{M} \mathrm{HCl}(5 \mathrm{~mL})$ was added slowly and the reaction stirred at room temperature for 10 min to allow hydrolysis of the acetal. The reaction was then diluted with ether and washed with water. The organic layer was then dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and concentrated in vacuo. The crude product was purified by column chromatography ( $9: 1$ ) petroleum ether/ethyl acetate to yield the title compound ( $0.70 \mathrm{~g}, 70 \%$ ) as a colourless oil. The data obtained is consistent with the reported values. $v_{\max }$ (neat) $/ \mathrm{cm}^{-1} 2683,1334,1168,1125 ;{ }^{1} \mathrm{H} \mathrm{NMR}\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}}$ $9.76(1 \mathrm{H}, \mathrm{d}, J=7.5, \mathrm{C} \underline{\mathrm{H} O}), 7.82-7.57(4 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}), 7.53(1 \mathrm{H}, \mathrm{d}, J=16.0, \mathrm{C}=\mathrm{CHAr}), 6.78$ $(1 \mathrm{H}, \mathrm{dd}, J=16.0,7.5, \mathrm{CHOCH}=\mathrm{C}){ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{C}} 193.1,150.4,134.8$, $131.7(\mathrm{q}, J=32.8), 131.2,130.0,129.7,127.5$ (q, $J=3.7), 125.2(\mathrm{q}, \quad J=3.8), 123.7((\mathrm{q}, \quad J=$ 272.4).
$\qquad$

## Preparation of 122

To a stirred solution of cinnamaldehyde $(118 \mathrm{mg}, 1.42 \mathrm{mmol}, 122 \mu \mathrm{l})$ in methanol ( 2 mL ) was added trifluoromethylpyrrolidine ( $198 \mathrm{mg}, 1.42 \mathrm{mmol}$ ) and allowed to stir for 2 min . Then hexafluorophosphoric $60 \% \mathrm{w} / \mathrm{w}$ solution in $\mathrm{H}_{2} \mathrm{O}(345 \mathrm{mg}, 1.42 \mathrm{mmol}, 210 \mu \mathrm{l})$ was added forming a yellow precipitate on reaction. The excess solvent was removed under reduced pressure and the crude mixture was recrystallised from the minimum amount of hot methanol. To yield the title compound ( $82 \%$ ) as an of colourless solid. mp $125{ }^{\circ} \mathrm{C} ;{ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}\right) \delta_{\mathrm{H}} 8.64\left(1 \mathrm{H}, \mathrm{d}, J=10.6, \mathrm{~N}^{+}=\mathrm{CH}\right), 8.12(1 \mathrm{H}, \mathrm{d}, J=15.2, \mathrm{CH}=\mathrm{CHAr})$, 7.89 ( $2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}$ ), $7.68(\mathrm{~m}, 1 \mathrm{H}, \mathrm{Ar}-\underline{\mathrm{H}}), 7.58$ (m, $2 \mathrm{H}, \mathrm{Ar}-\underline{\mathrm{H}}), 7.32$ ( $1 \mathrm{H}, \mathrm{dd}, J=10.6,15.2$, $\mathrm{C} \underline{\mathrm{H}}=\mathrm{CHAr}), 4.96\left(1 \mathrm{H}, \mathrm{m}, \mathrm{CHCF}_{3}\right), 4.41\left(2 \mathrm{H}, \mathrm{m}, \mathrm{N}^{+} \mathrm{CH}_{2}\right), 2.41\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2} \mathrm{CH}_{2}\right), 2.26(2 \mathrm{H}$, $\left.\mathrm{m}, \mathrm{CH}_{2} \mathrm{CH}_{2}\right) ;{ }^{13} \mathrm{C}\left(125 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}\right) \delta_{\mathrm{C}} 170.8,165.3,134.9,131.2,129.7,125.1,118.4$, $66.8(\mathrm{q}, J=31.3), 53.3,24.9,22.6,21.7 ; \mathrm{m} / \mathrm{z}(\mathrm{APCI}) 254\left(\mathrm{M}-\mathrm{PF}_{6}\right)$; HRMS (ES) (found $254.1152\left[\mathrm{M}-\mathrm{PF}_{6}\right]^{+} ; \mathrm{C}_{14} \mathrm{H}_{15} \mathrm{NF}_{3}$ requires 254.1151).

## Preparation of 3-(4-nitrophenyl)bicyclo[2.2.1]hept-5-ene-2-carbaldehyde

trans-4- Nitrocinnamaldehyde ( $390 \mathrm{mg}, 1.9 \mathrm{mmol}, 1.0 \mathrm{eq}$ ) was added to a solution of catalyst ( $10 \mathrm{~mol} \%, 0.19 \mathrm{mmol}$ ) in methanol $(2.0 \mathrm{~mL})$ at $25^{\circ} \mathrm{C}$ and the resulting mixture was stirred for 2 minutes to initiate iminium ion formation. Freshly cracked cyclopentadiene 19 ( $323 \mathrm{mg}, 4.9 \mathrm{mmol}, 0.38 \mathrm{~mL}, 2.5 \mathrm{eq}$ ) was added in a single aliquot and stirring was continued for 6 hours. The volatiles were removed under reduced pressure and the resulting organics were hydrolysed in a chloroform ( 2 mL ), water ( 1 mL ) trifluoroacetic acid ( 1 mL )

Chapter 10
mixture over night. Saturated sodium hydrogen carbonate solution ( 18 mL ) was added to neutralise the solution and the aqueous phase was extracted with dichloromethane ( $2 \times 20$ $\mathrm{mL})$. The combined organics were washed with water $(10 \mathrm{~mL})$ and dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$ prior to the removal of the volatiles under reduced pressure. The data measured was consistent with the literature. ${ }^{165} v_{\text {max }}$ (liquid film) $/ \mathrm{cm}^{-1} 1720,1591,1511,1344$.

## Preparation of $\boldsymbol{L}$-boc-phenylalaninemethylamide 154

Di-tert-butyldicarbonate ( $2.44 \mathrm{~g}, 11.2 \mathrm{mmol}$ ) was added to dry dichloromethane ( 70 mL ) at 0 ${ }^{\circ} \mathrm{C}$ and stirred. To this was added $L$-phenylalaninmethylamide $138(2 \mathrm{~g}, 11.2 \mathrm{mmol})$ in dichloromethane ( 10 mL ) slowly over a period of 5 mins . The reaction was allowed to reach room temperature and stirred overnight. The volatiles were removed under reduced pressure to yield a crude colourless solid which was purified by column chromatography eluting with (1:1) ethyl aceatate/petroleum ether to tiled the title compound ( $2.16 \mathrm{~g}, 82 \%$ ) as a colourless solid. Measured data is consistent with the literature. ${ }^{166} \mathrm{Mp} 139-141{ }^{\circ} \mathrm{C} ;{ }^{1} \mathrm{H}$ NMR
( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{H}} 7.30-7.14(5 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}), 6.13(1 \mathrm{H}, \mathrm{bs}, \mathrm{NH}), 5.22(1 \mathrm{H}, \mathrm{bs}, \mathrm{NH}) 4.34$ $\left(1 \mathrm{H}, \mathrm{dd}, J=7.6,7.2, \mathrm{CHCH}_{2}\right) 3.03\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CHCH}_{2}\right) 2.71\left(3 \mathrm{H}, \mathrm{d}, J=4.9, \mathrm{NCH}_{3}\right), 1.38(9 \mathrm{H}$, $\left.\mathrm{s} \mathrm{C}\left(\mathrm{CH}_{3}\right)_{3}\right) ;{ }^{13} \mathrm{C}$ NMR $\left(100 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{C}} 171.9(\mathrm{C}), 155.2(\mathrm{C}), 136.9(\mathrm{C}), 128.2(\mathrm{CH})$, $128.5(\mathrm{CH}), 126.8(\mathrm{CH}), 80.0(\mathrm{C}), 56.0(\mathrm{CH}), 38.9\left(\mathrm{CH}_{2}\right), 28.2\left(\mathrm{CH}_{3}\right), 26.0\left(\mathrm{CH}_{3}\right)$.

## Preparation of benzyl (S)-1-(methylcarbamoyl)-2-phenylethylcarbamate 155

Benzyl chloroformate ( $3.84 \mathrm{~g}, 22.5 \mathrm{mmol}, 3.21 \mathrm{~mL}$ ) and triethylamine ( $2.28 \mathrm{~g}, 22.5 \mathrm{mmol}$, 3.14 mL ) were added to dichloromethane ( 40 mL ) and stirred at $0^{\circ} \mathrm{C}$. To this was added $L$ phenylalaninmethylamide $138(4 \mathrm{~g}, 22.3 \mathrm{mmol})$ in dichloromethane ( 10 mL ), allowed to warm to room temperature and stirred overnight resulting in significant quantities of a colourless precipitate. The precipitate was filtered and washed with $\mathrm{H}_{2} \mathrm{O}$ and dichloromethane and subsequently purified by column chromatography eluting with ( $3: 1$ ) ethyl acetate/petroleum ether to yield the title compound ( $5.01 \mathrm{~g}, 72 \%$ ) as a colourless solid. $\mathrm{mp} 163-164{ }^{\circ} \mathrm{C}$; $v_{\max }(\mathrm{KBr}) / \mathrm{cm}^{-1} 3306,2353,1668.2,1652,1531,1285,1285,1239,1146$; ${ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}} 7.30-7.18(10 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}), 6.56(1 \mathrm{H}, \mathrm{bs}, \mathrm{NH}), 5.82(1 \mathrm{H}, \mathrm{bs}$, $\mathrm{NH}), 4.98\left(2 \mathrm{H}, \mathrm{dd}, J=12.6,28.4, \mathrm{OCH}_{2} \mathrm{Ar}\right), 4.24-4.18\left(1 \mathrm{H}, \mathrm{m}, \mathrm{CHCH}_{2}\right), 3.09(1 \mathrm{H}, \mathrm{dd}, J=$ $\left.5.0,13.9, \mathrm{CHCH}_{2}\right), 2.78\left(1 \mathrm{H}, \mathrm{dd}, J=9.4,13.9, \mathrm{CHCH}_{2}\right), 2.62\left(3 \mathrm{H}, \mathrm{d}, J=4.7, \mathrm{NHCH}_{3}\right)$.

Benzyl bromide ( $5.73 \mathrm{~g}, 33.5 \mathrm{mmol}, 3.98 \mathrm{~mL}$ ), triethylamine ( $3.39 \mathrm{~g}, 33.5 \mathrm{mmol}, 4.67 \mathrm{~mL}$ ) and $L$-phenylalaninmethylamide $138(6 \mathrm{~g}, 33.5 \mathrm{mmol})$ were added to toluene ( 70 mL ) and refluxed with rigorous stirring overnight. The solution was allowed to cool and $\mathrm{H}_{2} \mathrm{O}$ (30 $\mathrm{mL})$ added. The resulting solution was extracted with ethyl acetate ( $3 \times 50 \mathrm{~mL}$ ), the organics combined and concentrated under reduced pressure to yield the crude colourless solid which was purified by column chromatography eluting with (1:1) ethyl acetate/petroleum ether to give the title compound $(7.40 \mathrm{~g}, 82 \%)$ as a colourless solid. $\mathrm{mp} 53-54^{\circ} \mathrm{C}$; $\mathrm{v}_{\text {max }}\left(\mathrm{CHCl}_{3}\right)$ $/ \mathrm{cm}^{-1} 3377,3017,2942,2854,1950,1666,1531,1496,1454,1412,1332,1117 ;{ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}} 7.32-7.06(10 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}), 3.72\left(1 \mathrm{H}, \mathrm{d}, J=13.4, \mathrm{OCH}_{2} \mathrm{Ar}\right), 3.56(1 \mathrm{H}$, d, $\left.J=13.4, \mathrm{OCH}_{2} \mathrm{Ar}\right), 3.42\left(1 \mathrm{H}, \mathrm{dd} . ## Preparation of (14E)-2-(2,4-dinitrophenyl)-1-((3-phenylbicyclo[2.2.1]hept-5-en-2yl)methylene)hydrazine 160

Compound 160 was prepared in accordance to the method developed by Cavill. 3-Phenylbicyclo[2.2.1]hept-5-ene-2-carboxaldehyde (24 and 25) was reacted with 2,4dinitrophenylhydrazine to provide compound. Purification by flash chromatography on silica, eluting with ethyl acetate/petroleum ether (10:90), afforded the title compound as a yellow powder; Chiral HPLC analysis using a Chiralcel OD-R column, wavelength 215 nm ,
eluting with acetonitrile/water (80:20), flow rate of $0.5 \mathrm{~mL} / \mathrm{min}$, separated the chiral sample, retention times of 30.7 and 36.5 minutes (endo-diastereoisomers), 41.8 and 51.4 minutes (exo-diastereoisomers)

Exo-Diastereoisomer; $\lambda_{\max } 215 \mathrm{~nm}(\mathrm{EtOH}) ; \mathrm{mp} 160-162^{\circ} \mathrm{C}$; Found $379.1402\left(\mathrm{MH}^{+}\right.$ $\mathrm{C}_{20} \mathrm{H}_{18} \mathrm{~N}_{4} \mathrm{O}_{4}$ requires 379.1401); $v_{\max }(\mathrm{Nujol}) / \mathrm{cm}^{-1} 3289,1618,1586,1518,1502,1334$, $833,743,701 ; \delta_{\mathrm{H}}\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) 9.05(1 \mathrm{H}, \mathrm{d}, J=2.5, \mathrm{H}-3$ ), $8.22(1 \mathrm{H}, \mathrm{dd}, J=9.7,2.5$, $\left.\mathrm{H}-5^{\prime}\right), 7.85\left(1 \mathrm{H}, \mathrm{d}, J=9.7, \mathrm{H}-6^{\prime}\right), 7.66(1 \mathrm{H}, \mathrm{d}, J=6.1, \mathrm{~N}=\mathrm{CH}), 7.21(5 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}), 6.33$ $(1 \mathrm{H}, \mathrm{dd}, J=5.6,3.1, \mathrm{C}=\mathrm{CH}), 6.03(1 \mathrm{H}, \mathrm{dd}, J=5.6,2.8, \mathrm{C}=\mathrm{CH}), 3.52(1 \mathrm{H}, \mathrm{dd}, J=4.8,3.7$, $\mathrm{H}-3$ "), $3.21(1 \mathrm{H}, \mathrm{br}, \mathrm{C}=\mathrm{CHCH}), 2.99(1 \mathrm{H}, \mathrm{br}, \mathrm{C}=\mathrm{CHCH}), 2.63(1 \mathrm{H}, \operatorname{ddd}, J=6.1,4.8,1.4$, $\mathrm{H}-2$ "), $1.71\left(1 \mathrm{H}, \mathrm{br}, \mathrm{CH}_{2}\right), 1.60\left(1 \mathrm{H}, \mathrm{ddd}, J=9.4,9.4,1.6, \mathrm{CH}_{2}\right) ; \delta_{\mathrm{C}}\left(100 \mathrm{MHz}, \mathrm{CDCl}_{3}\right)$ 154.9 (CH), 145.0 (C), 142.7 (C), 137.8 (C), 136.7 (CH), 135.9 (CH), 128.8 (C), 128.7 $(\mathrm{CH}), 128.2(\mathrm{CH}), 127.8(\mathrm{CH}), 126.4(\mathrm{CH}), 123.5(\mathrm{CH}), 116.6(\mathrm{CH}), 49.9(\mathrm{CH}), 48.9(\mathrm{CH})$, $48.7(\mathrm{CH}), 48.1(\mathrm{CH}), 47.5\left(\mathrm{CH}_{2}\right) ; \mathrm{m} / \mathrm{z}(\mathrm{APcI}) 378.9\left(\mathrm{MH}^{+}, 51 \%\right), 338.4(40), 144.9(35)$, 106.9 (100);

## Preparation of $\boldsymbol{L}$-phenylalaninmethylamide 138

Compound 138 was prepared according to the procedure of MacMillan. ${ }^{167}$ To a solution of $L$-phenylalanine methyl ester hydrochloride ( $2 \mathrm{~g}, 9.27 \mathrm{mmol}$ ) in ethanol ( 2 mL ) was added methylamine $33 \%$ in ethanol solution ( $5 \mathrm{~mL}, 23.2 \mathrm{mmol}$ ) and the reaction stirred overnight at ambient temperature. The reaction mixture was then concentrated under reduced pressure to yield the crude reaction mixture. The mixture was purified by recrystallisation by displacement of the solid methylamine hydrochloride form solution with diethyl ether. The solid impurity was filtered and the filtrate concentrated under reduced pressure. The purification procedure was conducted as many times as necessary to yield the title compound ( $1.46 \mathrm{~g}, 81 \%$ ) as a colourless solid. $\mathrm{mp} 62{ }^{\circ} \mathrm{C} .{ }^{1} \mathrm{H} \mathrm{NMR}\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}}$ 7.39-7.16 (5H, m Ar-H), 3.72(1H, m, CH) $3.27\left(1 \mathrm{H}, \mathrm{dd}, J=4.32,13.70, \mathrm{CH}_{2}\right) 2.80(3 \mathrm{H}, \mathrm{d}, J$ 4.94, $\mathrm{NCH}_{3}$ ) $2.76\left(1 \mathrm{H}, \mathrm{dd}, J=9.16,13.70, \mathrm{CH}_{2}\right) 2.54\left(2 \mathrm{H}, \mathrm{bs}, \mathrm{NH}_{2}\right) ;{ }^{13} \mathrm{C}$ NMR ( 125 MHz ); $\delta_{\mathrm{C}} 174.8(\mathrm{C}), 138.0(\mathrm{C}), 129.3(\mathrm{CH}), 128.7(\mathrm{CH}), 126.8(\mathrm{CH}), 56.5(\mathrm{CH}), 41.0\left(\mathrm{CH}_{2}\right)$, $25.8\left(\mathrm{CH}_{3}\right) ; m / z$ (APCI) $179(\mathrm{M}+\mathrm{H}) ;$ HRMS (ES) (found $179.1180[\mathrm{M}+\mathrm{H}]^{+} ; \mathrm{C}_{10} \mathrm{H}_{14} \mathrm{~N}_{2} \mathrm{O}$ requires 179.1179).

## Preparation of (S)-2-(4-nitrobenzylideneamino)- $N$-methyl-3-phenylpropanamide 152

To a solution of $L$-phenylalaninemethylamide $183(0.50 \mathrm{~g}, 2.8 \mathrm{mmol})$ and $p$-TSA ( 48 mg , $0.28 \mathrm{mmol})$ in $\mathrm{MeOH}(5 \mathrm{~mL})$ was added 4-nitrobenzaldehyde $151(0.42 \mathrm{~g}, 2.8 \mathrm{mmol})$ and the reaction refluxed overnight. The reaction was allowed to cool and the volatiles removed under reduced pressure to yield the crude product. Purification was achieved using column chromatography eluting with ethyl acetate/petroleum ether (1:1) to afford the title compound as a viscous yellow oil. $v_{\max }\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right) / \mathrm{cm}^{-1} 3414,3054,2363,1676,1348,1265 ;{ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}} 8.25(2 \mathrm{H}, \mathrm{d}, J=8.8, \mathrm{Ar}-\underline{\mathrm{H}}), 7.75(2 \mathrm{H}, \mathrm{d}, J=8.8, \mathrm{Ar}-\underline{\mathrm{H}}), 7.57(1 \mathrm{H}, \mathrm{s}$,
$\mathrm{N}=\mathrm{CHAr}), 7.26-7.17(3 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}), 7.06(2 \mathrm{H}, \mathrm{d}, J=8.0, \mathrm{Ar}-\underline{\mathrm{H}}), 6.83(1 \mathrm{H}, \mathrm{bs}, \mathrm{NH}), 4.02$ $\left(1 \mathrm{H}, \mathrm{dd}, J=3.0,10.1, \mathrm{CHCH}_{2}\right), 3.47\left(1 \mathrm{H}, \mathrm{dd}, J=3.1,13.3, \mathrm{CHCH}_{2}\right), 2.95-2.90(4 \mathrm{H}, \mathrm{m}$, $\mathrm{CHCH}_{2}, \mathrm{NCH}_{3}$ ); $m / z(\mathrm{EI})(\mathrm{M}+) 311 ; \mathrm{HRMS}$ (EI) (found $310.1186[\mathrm{M}-\mathrm{H}]^{+} ; \mathrm{C}_{17} \mathrm{H}_{1} \mathrm{~N}_{3} \mathrm{O}_{3}$

## Preparation of (2R,5S)-5-benzyl-3-methyl-2-(4-nitrophenyl)imidazolidin-4-one hydrochloride 146

$L$-phenylalaninamethylamide 138 ( $400 \mathrm{mg}, 2.23 \mathrm{mmol}$ ), $p$-nitrobenzaldehyde $151(340 \mathrm{mg}$, 2.23 mmol ) and $p$-TSA ( $42 \mathrm{mg}, 0.22 \mathrm{mmol}, 0.1 \mathrm{eq}$ ) were dissolved in anhydrous DMF ( 2 mL ) and heated to $120^{\circ} \mathrm{C}$ for 30 minutes using microwave irradiation (max 100 watts). The reaction mixture was allowed to cool. $\mathrm{H}_{2} \mathrm{O}(10 \mathrm{~mL})$ and ethyl acetate $(10 \mathrm{~mL})$ were added and the aqueous layer extracted with ethyl acetate $(3 \times 10 \mathrm{~mL})$. The organics were then combined, dried over $\mathrm{MgSO}_{4}$, filtered and concentrated under reduced pressure. The resulting residue was purified using column chromatography eluting with (1:1) petroleum ether/ethyl acetate to yield the free base ( $94 \mathrm{mg}, 25 \%$ ) as a light yellow solid. ${ }^{1} \mathrm{H}$ NMR $\left(500 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}} 8.16(2 \mathrm{H}, \mathrm{d}, J=8.8, \mathrm{Ar}-\underline{\mathrm{H}}), 7.36(2 \mathrm{H}, \mathrm{d}, J=8.8, \mathrm{Ar}-\underline{\mathrm{H}}), 7.26-718$ ( $5 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}$ ), $4.88\left(1 \mathrm{H}, \mathrm{s}, \mathrm{C} \underline{H}(\mathrm{NR})_{2} \mathrm{Ar}\right), 4.00-3.97\left(1 \mathrm{H}, \mathrm{m}, \mathrm{CHCH}_{2}\right), 3.07(1 \mathrm{H}, \mathrm{dd}, J=4.2$, 13.8, $\mathrm{CH}_{2} \mathrm{CH}$ ), 2.96-2.92 ( $1 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2} \mathrm{CH}$ ), $2.52\left(3 \mathrm{H}, \mathrm{s}, \mathrm{NCH}_{3}\right) ;{ }^{13} \mathrm{C}$ NMR ( 125 MHz , $\left.\mathrm{CDCl}_{3}\right) ; \delta_{\mathrm{C}} 174.0(\mathrm{C}), 148.5(\mathrm{C}), 146.5(\mathrm{C}), 137.0(\mathrm{C}), 129.6(\mathrm{CH}), 128.6(\mathrm{CH}), 127.8(\mathrm{CH})$, $127.0(\mathrm{C}), 124.3(\mathrm{CH}), 76.5(\mathrm{CH}), 59.7(\mathrm{CH}), 38.5\left(\mathrm{CH}_{2}\right), 27.3\left(\mathrm{CH}_{3}\right) \mathrm{m} / \mathrm{z}(\mathrm{ES}) 312(\mathrm{M}+\mathrm{H})$.

The HCl salt was prepared by treating the catalyst to 5 equivalents of 3.8 M HCl in ether. The volatiles were removed under reduced pressure. The resulting solid was washed with ether and dried to yield the salt as a yellow solid (95\%) mp 181-183 ${ }^{\circ} \mathrm{C}$

Glycine methyl ester hydrochloride $186(1.00 \mathrm{~g}, 7.97 \mathrm{mmol})$ and potassium hydrogen carbonate $(2.00 \mathrm{~g}, 19.93 \mathrm{mmol})$ was stirred in acetonitrile $(60 \mathrm{~mL})$. To this suspension 2-bromoacetamide 195 ( $1.10 \mathrm{~g}, 7.97 \mathrm{mmol}$ ) was added and the reaction mixture refluxed for 8 h . After cooling to room temperature the mixture was filtered and the solvent removed under reduced pressure. The resulting solid was washed with chloroform ( 5 mL ) and acetone ( 5 mL ) to yield the title compound $(0.31 \mathrm{~g}, 34 \%)$ as a colourless solid. $\mathrm{mp} 100{ }^{\circ} \mathrm{C}$ (dec); $v_{\max }$ (Nujol) 3276, $1695 \mathrm{~cm}^{-1}$; ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{d}-6 \mathrm{DMSO}$ ) $\delta_{\mathrm{H}} 10.84(1 \mathrm{H}$, bs, $\mathrm{NH}), 3.42-3.32\left(4 \mathrm{H}, \mathrm{m}, \mathrm{NCH}_{2}\right), 3.12-3.04(1 \mathrm{H}, \mathrm{m}, \mathrm{NH}) ;{ }^{13} \mathrm{C}$ NMR ( $\left.62.5 \mathrm{MHz}, \mathrm{DMSO}\right) \delta_{\mathrm{C}}$ 173.3, 48.4. MS (ES) $m / z=114[\mathrm{M}]^{+} ; \mathrm{HRMS}(\mathrm{ES})$ (found $[\mathrm{M}]^{+}$114.0424; $\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{~N}_{2} \mathrm{O}_{2}$ requires 114.0424).

## Synthesis of piperazin-2,6-dione hydrochloride 190.HCl

Piperazin-2,6-dione ( $0.20 \mathrm{~g}, 1.75 \mathrm{mmol}$ ) was stirred in a solution of HCl in diethyl ether $(2.84 \mathrm{M}, 8.75 \mathrm{mmol}, 3 \mathrm{~mL})$ for five minutes. Then the mixture was filtered and the product was washed with diethyl ether. The HCl -salt was isolated as a colourless solid in $74 \%$ yield (196mg). mp $130{ }^{\circ} \mathrm{C}$ (dec). $v_{\text {max }}$ (Nujol)/ $\mathrm{cm}^{-1}: 3295,1692,1267 .{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{d}-6$ DMSO) $\delta_{H} 10.92(1 \mathrm{H}, \mathrm{bs}, \mathrm{NH}), 4.00-3.40(2 \mathrm{H}, \mathrm{bs}, \mathrm{NH}), 3.39\left(4 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{2}\right) ;{ }^{13} \mathrm{C}$ NMR (62.5 $\mathrm{MHz}, \mathrm{d}-6 \mathrm{DMSO}) \delta_{\mathrm{C}} 172.9,48.1$.

## Synthesis of 3-benzylpiperazin-2,6-dione 191

L-Phenylalanine ethyl ester hydrochloride $138(1.83 \mathrm{~g}, 7.97 \mathrm{mmol})$ and potassium hydrogen carbonate ( $2.00 \mathrm{~g}, 19.93 \mathrm{mmol}$ ) were stirred in toluene ( 60 mL ). To the suspension 2-bromoacetamide ${ }^{`} 95(1.10 \mathrm{~g}, 7.97 \mathrm{mmol})$ was added and the reaction mixture refluxed for 4 d . After being cooled to room temperature the mixture was filtered and the solvent was evaporated. The solid collected was washed with chloroform ( 5 mL ) then acetone ( 5 mL ) and dried to yield the title compound ( $179 \mathrm{mg}, 11 \%$ ) as a colourless solid. $\mathrm{mp} 157^{\circ} \mathrm{C}(\mathrm{dec})$; $\nu_{\text {max }}$ (Nujol) 3282, 1697, $1226 \mathrm{~cm}^{-1}$; ${ }^{1} \mathrm{H}$ NMR ( 400 MHz , d-6 DMSO) $\delta_{\mathrm{H}} 10.78(1 \mathrm{H}$, bs, $\mathrm{N} \underline{\mathrm{H}}), 7.29-7.17(5 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}), 3.60-3.54(1 \mathrm{H}, \mathrm{m}, \mathrm{NCH}), 3.47-3.31\left(2 \mathrm{H}, \mathrm{m}, \mathrm{NCH}_{2}\right), 3.16$ $\left(1 \mathrm{H}, \mathrm{dd}, J=3.8,14.2, \mathrm{CH}_{2} \mathrm{Ar}\right), 2.93-2.86(1 \mathrm{H}, \mathrm{m}, \mathrm{NH}), 2.75\left(1 \mathrm{H}, \mathrm{dd}, J=9.7,14.2, \mathrm{CH}_{2} \mathrm{Ar}\right)$; ${ }^{13} \mathrm{C}$ NMR ( 100 MHz , d-6 DMSO) $\delta_{\mathrm{C}} 173.8(\mathrm{C}), 139.1(\mathrm{C}), 129.8(\mathrm{CH}), 128.5(\mathrm{CH})$, $126.6(\mathrm{CH}), 58.6(\mathrm{CH}), 48.1\left(\mathrm{CH}_{2}\right), 35.6\left(\mathrm{CH}_{2}\right) ; \mathrm{MS}(\mathrm{ES}) \mathrm{m} / \mathrm{z}=246[\mathrm{M}+\mathrm{MeCN}+\mathrm{H}]^{+}$, $205[\mathrm{M}+\mathrm{H}]^{+}$; HRMS (ES) calculated for $\mathrm{C}_{11} \mathrm{H}_{12} \mathrm{~N}_{2} \mathrm{O}_{2}[\mathrm{M}]^{+}$205.0972, found 205.0972.

## Synthesis of 3-benzylpiperazin-2,6-dione hydrochloride 191.HCl

3-Benzylpiperazin-2,6-dione $191(0.10 \mathrm{~g}, 0.49 \mathrm{mmol})$ was stirred in a solution of HCl in diethyl ether ( $2.84 \mathrm{M}, 1.00 \mathrm{~mL}, 2.45 \mathrm{mmol}$ ) for five minutes. Then the mixture was filtered and the product was washed with diethyl ether. The HCl -salt was isolated ( $92 \mathrm{mg}, 77 \%$ ) as a colourless solid. $v_{\max }$ (Nujol) 3509, 3338, 1737, $1267 \mathrm{~cm}^{-1} ;{ }^{1} \mathrm{H}$ NMR ( 400 MHz , d-6 DMSO) $\delta_{\mathrm{H}} 11.75(1 \mathrm{H}, \mathrm{bs}, \mathrm{NH}), 11.00-9.50(2 \mathrm{H}, \mathrm{bs}, \mathrm{NH}), 7.35-7.23$ ( $5 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}$ ), 4.39 ( $1 \mathrm{H}, \mathrm{bs}, \mathrm{NC} \underline{\mathrm{H}}$ ), $3.99-3.88\left(2 \mathrm{H}, \mathrm{m}, \mathrm{NCH}_{2}\right), 3.37\left(1 \mathrm{H}, \mathrm{dd}, J=6.2,14.4, \mathrm{CH}_{2} \mathrm{Ar}\right), 3.15(1 \mathrm{H}, \mathrm{dd}$, $\left.J=6.5,14.3, \mathrm{CH}_{2} \mathrm{Ar}\right) ;{ }^{13} \mathrm{C}$ NMR ( $62.5 \mathrm{MHz}, \mathrm{d}-6 \mathrm{DMSO}$ ) $\delta_{\mathrm{C}} 168.3,166.6,135.6,129.6$, 128.5, 127.0, 55.9, 44.5, 33.2; MS (ES) $m / z=246[\mathrm{M}+\mathrm{MeCN}+\mathrm{H}-\mathrm{HCl}]^{+}, 205[\mathrm{M}+\mathrm{H}-\mathrm{HCl}]^{+}$.

## Synthesis of 2-amino- $N$-methylacetamide 196

Glycine ethyl ester hydrochloride $186(3.00 \mathrm{~g}, 21.50 \mathrm{mmol})$ was stirred in a solution of methylamine in ethanol $(33 \%, 6.00 \mathrm{~mL}, 48.00 \mathrm{mmol})$ for 3 days. Then the solvent was removed under reduced pressure and the resulting residue dissolved in methanol. Diethyl ether was added slowly to the solution until the starting material began to precipitate as a colourless solid. The suspension was then filtered followed by concentration of the filtrate under reduced pressure to yield the title compound $(1.17 \mathrm{~g}, 25 \%)$ as a colourless oil. $v_{\max }$ (neat)/ $\mathrm{cm}^{-1}: 3298,1651,857,831 ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{d}-6 \mathrm{DMSO}$ ) $\delta_{\mathrm{H}} 7.64(1 \mathrm{H}, \mathrm{bs}, \mathrm{NH})$, $2.91\left(2 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{2}\right), 2.46\left(3 \mathrm{H}, \mathrm{d}, J=6.5, \mathrm{NHCH}_{3}\right), 1.62(2 \mathrm{H}, \mathrm{bs}, \mathrm{NH}) ;{ }^{13} \mathrm{C}$ NMR ( 62.5 MHz , d-6 DMSO) $\delta_{\mathrm{C}} 173.3(\mathrm{C}) 44.8\left(\mathrm{CH}_{2}\right) 25.2\left(\mathrm{CH}_{3}\right) ; \mathrm{MS}(\mathrm{ES}) \mathrm{m} / \mathrm{z}=88[\mathrm{M}]^{+}$; HRMS (ES) calculated for $\mathrm{C}_{3} \mathrm{H}_{8} \mathrm{~N}_{2} \mathrm{O}[\mathrm{M}]^{+} 88.0631$, found 88.0632.

## Synthesis of 1-methylpiperazin-2,6-dione 192

2-Amino- $N$-methylacetamide 196 ( $0.50 \mathrm{~g}, 5.67 \mathrm{mmol}$ ) and potassium hydrogen carbonate $(1.40 \mathrm{~g}, 14.0 \mathrm{mmol})$ were stirred in acetronitrile $(60 \mathrm{~mL})$ and stirred vigorously to create a suspension. Ethylbromoacetate $195(0.95 \mathrm{~g}, 5.67 \mathrm{mmol})$ was added and the reaction mixture was refluxed for 2 days. The reaction mixture was allowed to cool to room temperature and the precipitate filtered. The filtrate was concentrated under reduced pressure and the resulting residue purified by column chromatography eluting with ethyl acetate to provide the title compound $(0.21 \mathrm{~g}, 29 \%)$ as a light purple solid. $\mathrm{mp} 78-82{ }^{\circ} \mathrm{C}$; $v_{\max }(\mathrm{Nujol}) / \mathrm{cm}^{-1}$ : 3320, 1660, 1300, 1161; ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{H}} 3.66\left(\mathrm{~s}, 4 \mathrm{H}, \mathrm{NCH}_{2}\right), 3.09(\mathrm{~s}, 3 \mathrm{H}$, $\left.\mathrm{NCH}_{3}\right), 1.65(1 \mathrm{H}, \mathrm{bs}, \mathrm{NH}) ;{ }^{13} \mathrm{C}$ NMR ( $62.5 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{C}} 171.4(\mathrm{C}) 49.7\left(\mathrm{CH}_{2}\right) 25.4\left(\mathrm{CH}_{3}\right)$ MS (ES) $m / z=128[M]^{+} ;$HRMS (ES) calculated for $\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{~N}_{2} \mathrm{O}_{2}[\mathrm{M}]^{+}$128.0580, found 128.0578.

## Synthesis of 1-methylpiperazin-2,6-dione hydrochloride 192.HCl

1-Methylpiperazin-2,6-dione $192(0.15 \mathrm{~g}, 1.20 \mathrm{mmol})$ was stirred in a solution of HCl in diethyl ether $(2.84 \mathrm{M}, 2.50 \mathrm{~mL}, 6.00 \mathrm{mmol} \mathrm{HCl})$ for five minutes. Then the mixture was filtered and the solid was washed with diethyl ether. The product was isolated as a light purple solid in $82 \%$ yield ( 0.16 g ). $\mathrm{mp}>190{ }^{\circ} \mathrm{C}$; $v_{\max }$ (Nujol)/ $\mathrm{cm}^{-1} 3319,1667,1166 ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{d}-6 \mathrm{DMSO}$ ) $\delta_{\mathrm{H}} 10.21(2 \mathrm{H}, \mathrm{bs}, \mathrm{NH}), 4.07\left(4 \mathrm{H}, \mathrm{s}, \mathrm{NCH}_{2}\right), 3.03(3 \mathrm{H}, \mathrm{s}$, $\left.\mathrm{NCH}_{3}\right) ;{ }^{13} \mathrm{C}$ NMR ( $62.5 \mathrm{MHz}, \mathrm{d}-6 \mathrm{DMSO}$ ) $\delta_{\mathrm{C}} 165.9(\mathrm{C}), 44.6\left(\mathrm{CH}_{2}\right), 25.6\left(\mathrm{CH}_{3}\right) . \mathrm{MS}(\mathrm{ES}) \mathrm{m} / \mathrm{z}$ $=128[\mathrm{M}-\mathrm{HCl}]^{+}$.

## Synthesis of 3-benzyl-1-methylpiperazin-2,6-dione

(S)-2-Amino-N-methyl-3-phenylpropanamide $193(1.00 \mathrm{~g}, 5.61 \mathrm{mmol})$ and potassium hydrogen carbonate ( $1.40 \mathrm{~g}, 14.0 \mathrm{mmol}$ ) were stirred in acetonitrile ( 60 mL ). To the suspension ethylbromoacetate $195(0.95 \mathrm{~g}, 5.67 \mathrm{mmol})$ was added and the reaction mixture was refluxed for 3 d . The reaction mixture was allowed to cool to room temperature then the mixture was filtered and the solvent removed under reduced pressure. The residue was purified by column chromatography eluting with (1:1) ethyl acetate/petroleum ether to yield the title compound ( $0.88 \mathrm{~g}, 72 \%$ ) as a light yellow solid. $\mathrm{mp} 49-52^{\circ} \mathrm{C}$; $\mathrm{v}_{\max }$ (Nujol) 3295, $1660,1292,1127 \mathrm{~cm}^{-1} ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{H}} 7.37-7.26(5 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}), 3.82(1 \mathrm{H}$, d, $J=17.4, \mathrm{NCH}_{2}$ ), $3.74-3.70\left(1 \mathrm{H}, \mathrm{m}, \mathrm{NCH}_{2}\right), 3.59(1 \mathrm{H}, \mathrm{d}, J=17.5, \mathrm{NCH}), 3.42(1 \mathrm{H}, \mathrm{dd}, J$ $\left.=4.0,14.0, \mathrm{CH}_{2} \mathrm{Ar}\right), 3.18\left(3 \mathrm{H}, \mathrm{s}, \mathrm{NCH}_{3}\right), 3.04\left(1 \mathrm{H}, \mathrm{dd}, J=8.8,14.0, \mathrm{CH}_{2} \mathrm{Ar}\right), 1.67(\mathrm{bs}, 1 \mathrm{H}$, $\mathrm{NH}) ;{ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{C}} 172.5$ (C), 171.1 (C), 136.7 (C), 129.4 (CH), 128.9 $(\mathrm{CH}), 127.2(\mathrm{CH}), 59.8(\mathrm{CH}), 49.3\left(\mathrm{CH}_{2}\right), 36.6\left(\mathrm{CH}_{2}\right), 25.9\left(\mathrm{CH}_{3}\right) . \mathrm{MS}(\mathrm{ES}) \mathrm{m} / \mathrm{z}=260$ $[\mathrm{M}+\mathrm{MeCN}+\mathrm{H}]^{+}, 219[\mathrm{M}+\mathrm{H}]^{+}$; HRMS (ES) calculated for $\mathrm{C}_{12} \mathrm{H}_{14} \mathrm{~N}_{2} \mathrm{O}_{2}[\mathrm{M}]^{+}$219.1128, found 219.1127.

Synthesis of 3-benzyl-1-methylpiperazin-2,6-dione hydrochloride 193.HCl

3-Benzyl-1-methylpiperazin-2,6-dione $193(0.50 \mathrm{~g}, 2.30 \mathrm{mmol})$ was stirred in a solution of HCl in diethyl ether $(2.84 \mathrm{M}, 4.00 \mathrm{~mL}, 11.50 \mathrm{mmol} \mathrm{HCl})$ for five minutes. Then the mixture was filtered and the solid was washed with diethyl ether. The product was isolated as a colourless solid in $87 \%$ yield ( 0.52 g ). mp $170{ }^{\circ} \mathrm{C}$ (dec). $v_{\text {max }}$ (Nujol) $3371,1687 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{d}-6 \mathrm{DMSO}$ ) $\delta_{\mathrm{H}} 11.50-9.50(2 \mathrm{H}, \mathrm{bs}, \mathrm{NH}), 7.37-7.26(5 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}), 4.44$ $(1 \mathrm{H}, \mathrm{t}, J=5.8, \mathrm{NCH}), 4.04\left(2 \mathrm{H}, \mathrm{s}, \mathrm{NCH}_{2}\right), 3.39\left(1 \mathrm{H}, \mathrm{dd}, J=6.5,14.4, \mathrm{CH}_{2} \mathrm{Ar}\right), 3.18(\mathrm{dd}, J$ $\left.=6.3,14.3, \mathrm{CH}_{2} \mathrm{Ar}\right), 3.03\left(3 \mathrm{H}, \mathrm{s}, \mathrm{NCH}_{3}\right) .{ }^{13} \mathrm{C} \mathrm{NMR}(62.5 \mathrm{MHz}, \mathrm{d}-6 \mathrm{DMSO}) \delta_{\mathrm{C}} 136.0(\mathrm{C})$ $129.6(\mathrm{CH}) 128.4(\mathrm{CH}) 126.9(\mathrm{CH}) 56.8(\mathrm{CH}) 45.3\left(\mathrm{CH}_{2}\right) 34.1\left(\mathrm{CH}_{3}\right) 25.9\left(\mathrm{CH}_{2}\right)$ carbonyl carbons were not observed; MS (ES) $\mathrm{m} / \mathrm{z}=260[\mathrm{M}+\mathrm{MeCN}+\mathrm{H}-\mathrm{HCl}]^{+}, 219[\mathrm{M}+\mathrm{H}-\mathrm{HCl}]^{+}$.

## Synthesis of piperazin-2-one hydrochloride 189.HCl

Piperazin-2-one 189 ( $0.25 \mathrm{~g}, 2.50 \mathrm{mmol}$ ) was stirred in a solution of HCl in diethyl ether $(2.84 \mathrm{M}, 4.40 \mathrm{~mL}, 12.50 \mathrm{mmol} \mathrm{HCl})$ for five minutes. Then the mixture was filtered and the solid was washed with diethyl ether. The product was isolated as an orange solid in $60 \%$ yield ( 0.21 g ). mp 96-98 ${ }^{\circ} \mathrm{C}$; $v_{\text {max }}$ (Nujol) $3301,1651,1120 \mathrm{~cm}^{-1} ;{ }^{1} \mathrm{H}$ NMR ( 400 MHz , d-6 DMSO) $\delta_{\mathrm{H}} 7.78(1 \mathrm{H}, \mathrm{bs}, \mathrm{NH}), 6.00-4.00(2 \mathrm{H}, \mathrm{bs}, \mathrm{NH}), 3.25\left(2 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{2} \mathrm{CO}\right), 3.18-3.15(2 \mathrm{H}$, $\left.\mathrm{m}, \mathrm{CH}_{2} \mathrm{CH}_{2}\right), 2.88\left(2 \mathrm{H}, \mathrm{t}, J=5.7, \mathrm{CH}_{2} \mathrm{CH}_{2}\right) ;{ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{d}-6 \mathrm{DMSO}$ ) $\delta_{\mathrm{C}} 167.8(\mathrm{C})$, $48.7\left(\mathrm{CH}_{2}\right), 41.7\left(\mathrm{CH}_{2}\right), 41.2\left(\mathrm{CH}_{2}\right)$.
$\qquad$ hexafluorophosphate 125

1-Methylpiperazin-2,6-dione $192(0.05 \mathrm{mg}, 0.39 \mathrm{mmol})$ was dissolved in methanol ( 5.00 mL ) and ( $E$ )-cinnamaldehyde $\mathbf{2 0 ( 4 9 . 0 0 ~} \mu \mathrm{L}, 0.39 \mathrm{mmol}$ ) was added, followed by $\mathrm{HPF}_{6}(60 \%$ in water, $57.00 \mu \mathrm{~L}, 0.39 \mathrm{mmol}$ ). After a few seconds a yellow precipitate was observed. The mixture was stirred for a further 5 minutes and then the precipitate was separated by filtration. The solid was washed with methanol to yield the title compound ( $0.11 \mathrm{~g}, 72 \%$ ) as a yellow solid. $v_{\max }$ (Nujol)/ $\mathrm{cm}^{-1}: 3338,1752,1685,1625 ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{d}-3 \mathrm{MeCN}$ ) $\delta_{\mathrm{H}} 8.35\left(1 \mathrm{H}, \mathrm{d}, J=10.8 \mathrm{~N}^{+}=\mathrm{CH}\right), 8.04(1 \mathrm{H}, \mathrm{d}, J=15.0, \mathrm{CH}=\mathrm{CHAr}), 7.85(2 \mathrm{H}, \mathrm{d}, J=7.4$, $\operatorname{Ar}-\underline{H}), 7.65-7.61(1 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}), 7.55-7.51(2 \mathrm{H}, \mathrm{m}, \operatorname{Ar}-\underline{\mathrm{H}}), 7.37(1 \mathrm{H}, \mathrm{dd}, J=10.8,15.0$, $\mathrm{C} \underline{\mathrm{H}}=\mathrm{CHAr}), 4.93\left(2 \mathrm{H}, \mathrm{s}, \mathrm{N}^{+} \underline{\mathrm{H}}_{2}\right), 4.80\left(2 \mathrm{H}, \mathrm{s}, \mathrm{N}^{+} \mathrm{CH}_{2}\right), 3.08\left(3 \mathrm{H}, \mathrm{s}, \mathrm{NCH}_{3}\right) .{ }^{13} \mathrm{C}$ NMR ( 125 $\mathrm{MHz}, \mathrm{d}-3 \mathrm{MeCN}) \delta_{\mathrm{C}} 171.0(\mathrm{CH}), 165.0(\mathrm{CH}), 134.9(\mathrm{CH}), 133.5(\mathrm{C}), 131.1(\mathrm{CH}), 129.7(\mathrm{CH})$, 116.2( CH$), 58.0\left(\mathrm{CH}_{2}\right), 52.0\left(\mathrm{CH}_{2}\right), 26.1\left(\mathrm{CH}_{3}\right)$, carbonyl carbons were not observed; For Xray structure see (Appendix)

## Synthesis of ethyl 2-benzylbromoacetate 208

Under nitrogen and at $-35^{\circ} \mathrm{C}$ ethyl-2-benzylacetoacetate ( $10.00 \mathrm{~g}, 45.40 \mathrm{mmol}$ ) was added to a solution of sodium ethoxide ( $3.09 \mathrm{~g}, 45.50 \mathrm{mmol}$ ) in ethanol ( 75 mL ). N bromosuccinimide ( $8.08 \mathrm{~g}, 45.50 \mathrm{mmol}$ ) was added slowly and the resulting mixture was stirred for 1 h at rt . After the addition of water $(75 \mathrm{~mL})$ the solution was extracted with diethyl ether ( $3 \times 50 \mathrm{~mL}$ ) and the organic layer was dried over $\mathrm{NaSO}_{4}$. The intermediate 207 was purified by column chromatography (petroleum ether: dichloromethane 1.5:1). Then the bromonated intermediate was dissolved in a solution of sodium ethoxide ( $3.09 \mathrm{~g}, 45.50$ mmol ) in ethanol ( 75 mL ) and was stirred for 3 h . Water ( 75 mL ) was added and the solution was extracted with diethyl ether ( $3 \times 50 \mathrm{~mL}$ ) and dried over $\mathrm{NaSO}_{4}$, filtered and concentrated
under reduced pressure to yield the title compound ( $6.80 \mathrm{~g}, 82 \%$ ) as a yellow liquid. $\mathbb{R}$ (Nujol) 3295, 1739, $1605 \mathrm{~cm}^{-1} ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{H}} 7.26-7.14$ ( $5 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}$ ), 4.36-4.30 ( $1 \mathrm{H}, \mathrm{m}, \mathrm{C} \underline{\mathrm{HBr}}$ ), 4.14-4.07 ( $2 \mathrm{H}, \mathrm{m}, \mathrm{CO}_{2} \mathrm{CH}_{2}$ ), $3.37\left(1 \mathrm{H}, \mathrm{dd}, J=5.5,14.1, \mathrm{Ar}-\mathrm{CH}_{2}\right)$, $3.17\left(1 \mathrm{H}, \mathrm{dd}, J=7.1,14.1, \operatorname{Ar}-\mathrm{CH}_{2}\right), 1.15\left(3 \mathrm{H}, \mathrm{t}, J=3.9, \mathrm{CH}_{2} \mathrm{CH}_{3}\right) ;{ }^{13} \mathrm{C}$ NMR $(125 \mathrm{MHz}$, $\left.\mathrm{CDCl}_{3}\right) \delta_{\mathrm{C}} 169.4(\mathrm{C}), 136.8(\mathrm{C}), 129.2(\mathrm{CH}), 128.6(\mathrm{CH}), 127.3(\mathrm{CH}), 62.0\left(\mathrm{CH}_{2}\right), 45.5(\mathrm{CH})$, $41.1\left(\mathrm{CH}_{2}\right), 13.9\left(\mathrm{CH}_{3}\right)$.

## Synthesis of tricyclo[5.2.1.0~2,6~]dec-8-en-3-one

2-Cyclohexen-1-one $198(290 \mathrm{mg}, 3.00 \mathrm{mmol}, 0.29 \mathrm{~mL})$ was added to water $(0.75 \mathrm{~mL})$ at 4 ${ }^{\circ} \mathrm{C}$, followed by conc. $\mathrm{HCl}(0.05 \mathrm{~mL}, 0.60 \mathrm{mmol})$. The mixture was stirred for five minutes and cyclopentadiene 19 ( $0.71 \mathrm{~mL}, 9.00 \mathrm{mmol}$ ) was added dropwise. The mixture was stirred for 4 d and was then diluted with (5:1)petroleum ether/diethyl ether ( 12 mL ) and submitted directly to column chromatography eluting with petroleum ether/diethyl ether (5:1) to yield the title compound ( $6.9 \mathrm{mg}, 1.4 \%$ ) as a yellow oil. Data was consistent with the literature. ${ }^{168}$ ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{H}}$ 6.13-6.11 $(1 \mathrm{H}, \mathrm{m}), 5.98-5.94(1 \mathrm{H}, \mathrm{m}), 4.14-4.07(2 \mathrm{H}, \mathrm{m})$, $3.20(1 \mathrm{H}, \mathrm{s}), 2.82(1 \mathrm{H}, \mathrm{s}), 2.68-2.60(2 \mathrm{H}, \mathrm{m}), 2.28-2.23(1 \mathrm{H}, \mathrm{m}), 1.91-1.82(2 \mathrm{H}, \mathrm{m}), 1.73-$ $1.59(2 \mathrm{H}, \mathrm{m}), 1.40-1.37(1 \mathrm{H}, \mathrm{m}), 125-1.23(1 \mathrm{H}, \mathrm{m}), 0.71-0.55(1 \mathrm{H}, \mathrm{m}) ;{ }^{13} \mathrm{C}$ NMR ( 62.5 $\left.\mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{C}} 215.6,137.7,135.0,51.7,48.4,46.6,45.2,41.4,39.4,28.0,21.8 ; \mathrm{MS}$ (ES) $\mathrm{m} / \mathrm{z}=162[\mathrm{M}]^{+}$.

## Synthesis of 1-(3-methylbicyclo[2.2.1]hept-5-en-2-yl)propan-1-one 176

Catalyst ( 0.12 mmol ) was dissolved in water $(203.00 \mu \mathrm{~L})$ and cooled to $4^{\circ} \mathrm{C}$. 4-hexen-3-one $175(70.00 \mu \mathrm{~L}, 0.61 \mathrm{mmol})$ was added, followed by perchloric acid ( $70 \%$ in water, 10.50 $\mu \mathrm{L}, 0.12 \mathrm{mmol})$ and the mixture was stirred for five minutes. Cyclopentadiene 19 ( $75.00 \mu \mathrm{~L}$, 0.91 mmol ) was added and the stirring was continued for 24 h . Then the mixture was diluted
with petroleum ether/diethyl ether (9:1) and directly purified by column chromatography with the same solvent system to yield the title compound ( $32 \mathrm{mg}, 16 \%$ ) as a colourless liquid. Data was consistent with the literature. ${ }^{168}{ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}}$ 6.17-6.15 $(1 \mathrm{H}, \mathrm{m}, \mathrm{CH}=\mathrm{CH}), 5.84-5.82(1 \mathrm{H}, \mathrm{m}, \mathrm{CH}=\mathrm{CH}), 3.06(\mathrm{bs}, 1 \mathrm{H}, \mathrm{CH}=\mathrm{CHC} \underline{H}), 2.39-2.33(4 \mathrm{H}$, $\left.\mathrm{m}, \mathrm{CH}_{2} \mathrm{COCH}, \mathrm{CH}=\mathrm{CHC} \underline{H},\right), 1.84-1.82\left(1 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2} \mathrm{CH}\right), 1.52\left(1 \mathrm{H}, m, \mathrm{CH}_{2} \mathrm{CH}\right), 1.37(1 \mathrm{H}$, m, $\mathrm{CH}_{2} \mathrm{CH}$ ), $1.09\left(3 \mathrm{H}, \mathrm{d}, J=7.0 \mathrm{CHCH}_{3}\right), 0.95\left(3 \mathrm{H}, \mathrm{t}, J=7.4, \mathrm{CH}_{2} \mathrm{CH}_{3}\right)$; ${ }^{13} \mathrm{C}$ NMR ( 62.5 $\left.\mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{C}} 211.7,138.5,132.5,60.7,49.0,46.3,35.7,34.7,21.0,7.8$.

## Preparation of (S)-5-methyl-5-nitro-4-phenylhexan-2-one 229

The enetaionenriched product was prepared in accordance with the method of Jorgensen. ${ }^{169}$ $E$-4-phenylbut-3-en-2-one ( $37 \mathrm{mg}, 0.25 \mathrm{mmol}$ ) was place in nitropropanane ( 496 mg 5.5 $\mathrm{mmol}, 0.5 \mathrm{~mL}$ ), To this was added $20 \mathrm{~mol} \%$ of catalyst $10(11 \mathrm{mg} \mathrm{g}, 0.05 \mathrm{mmol})$ and the reaction allowed to stir at ambient temperature for 14 days. On completion of the reaction the volatiles were removed under reduced pressure. The resulting residue was purified by column chromatography eluting with. The e.e was determined by Chrial HPLC using Chiracel OJ column eluting $10 \%$ IPA in hexanes flow rate $1 \mathrm{~mL} \mathrm{~min}^{-1}$. Enatiomers were determined by analogy. $\mathrm{mp}{ }^{\circ} \mathrm{C} ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{H}}$ 7.33-7.24 (3H, m, Ar-H), 7.21-7.16 (2H, m, Ar-H), $3.92\left(1 \mathrm{H}, \mathrm{dd}, J=10.8,3.6, \mathrm{CHCH}_{2}\right), 3.09(1 \mathrm{H}, \mathrm{dd}, \mathrm{J}=16.8,10.8$, $\left.\mathrm{CHCH}_{2}\right) 2.71$, ( $1 \mathrm{H}, \mathrm{dd}, J=16.8,3.0, \mathrm{CHCH}_{2}$ ) $2.03\left(3 \mathrm{H}, \mathrm{s}, \mathrm{COCH}_{3}\right) 1.55\left(3 \mathrm{H}, \mathrm{s}, \mathrm{NO}_{2} \mathrm{CCH}_{3}\right)$ $1.47\left(3 \mathrm{H}, \mathrm{s}, \mathrm{NO}_{2} \mathrm{CCH}_{3}\right){ }^{13} \mathrm{C}$ NMR $\left(100 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{C}} \quad 205.2(\mathrm{C}), 137.5(\mathrm{C}), 129.1(\mathrm{CH})$, $128.5(\mathrm{CH}), 127.9(\mathrm{C}), 91.0(\mathrm{C}), 48.8\left(\mathrm{CH}_{2}\right), 44.0(\mathrm{CH}), 30.3\left(\mathrm{CH}_{3}\right), 25.8\left(\mathrm{CH}_{3}\right), 22.3\left(\mathrm{CH}_{3}\right)$.

## Preparation of 5-nitro-4-phenylpentan-2-one 237

Compound 237 was prepared in accordance with the procedure of List. ${ }^{170}$ To a suspension of $L$-proline ( $120 \mathrm{mg} 1.01 \mathrm{mmol}, 15 \mathrm{~mol} \%$ ) in DMSO ( 54 mL ) was added trans-beta nitro styrene ( $1 \mathrm{~g}, 6.7 \mathrm{mmol}$ ) and acetone $(10.6 \mathrm{~g}, 182 \mathrm{mmol}, 13.4 \mathrm{~mL})$ and the mixture stirred overnight at room temperature. To this was added ethyl acetate ( 50 mL ) and saturated $\mathrm{NH}_{4} \mathrm{Cl}$ solution ( 50 mL ). The aqueous layer was extracted with ethyl acetate ( $3 \times 50 \mathrm{~mL}$ ), the organics combined dried over $\mathrm{MgSO}_{4}$ filtered and concentrated under reduced pressure. The resulting residue was purified using column chromatography eluting with (1:1) petroleum ether/ethyl acetate to yield the title compound ( $1.31 \mathrm{~g}, 95 \%$ ) as a colourless solid. ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{H}} 7.35-7.21(5 \mathrm{H}, \mathrm{m} \mathrm{Ar}-\mathrm{H}), 4.70\left(1 \mathrm{H}, \mathrm{dd}, J=6.9,6.9, \mathrm{CH}_{2} \mathrm{NO}_{2}\right), 4.61$ ( $1 \mathrm{H}, \mathrm{dd}, J=7.7,7.7, \mathrm{C}_{2} \mathrm{NO}_{2}$ ), $4.01\left(1 \mathrm{H}, \mathrm{m}, \mathrm{ArCHCH}_{2}\right), 2.93\left(2 \mathrm{~h}, \mathrm{~d}, J=7.0, \mathrm{CH}_{2} \mathrm{CO}\right), 2.13$ (3H, s, $\mathrm{COCH}_{3}$ ).

## Preparation of (S)-N-methyl-3-phenylpropane-1,2-diamine, 235

Compound 235 was prepared in accordance with the procedure of Jørgensen. $L$-phenylalaninmethylamide $138(1 \mathrm{~g}, 5.6 \mathrm{mmol})$ was dissolved in anhydrous THF ( 30 mL ) and lithium aluminium hydride $(1.07 \mathrm{~g}, 29.1 \mathrm{mmol}, 5 \mathrm{eq})$ added. The reaction mixture was refluxed for 48 h and allowed to cool before being filtered through celite. The filtrate was collected and concentrated under reduced pressure. The resulting oil was purified by column chromatography eluting with methanol to yield the title compound ( $0.23 \mathrm{~g}, 25 \%$ ) as a colourless oil data consistent with reported values. ${ }^{1} \mathrm{H} \mathrm{NMR}\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}} 7.32-7.19$ ( $5 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}$ ) 3.14-3.08 ( $1 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2} \mathrm{CHCH}_{2}$ ), $2.80\left(1 \mathrm{H}, \mathrm{dd}, J=4.9,13.3, \mathrm{ArCH}_{2}\right) 2.67$ ( $1 \mathrm{H}, \operatorname{dd}, J=3.9,11.7, \mathrm{ArCH}_{2}$ ), 2.53-2.44 ( $5 \mathrm{H}, \mathrm{m}, \mathrm{NCH}_{3}, \mathrm{NCH}_{2}$ ); ${ }^{13} \mathrm{C} \mathrm{NMR}(125 \mathrm{MHz}$,
$\left.\mathrm{CDCl}_{3}\right) ; \delta_{\mathrm{C}} 139.0(\mathrm{C}), 129.3(\mathrm{CH}), 128.5(\mathrm{CH}), 126.3(\mathrm{C}), 57.9\left(\mathrm{CH}_{2}\right), 52.1(\mathrm{CH}), 42.7\left(\mathrm{CH}_{3}\right)$. $m / z$ (APCI) $(\mathrm{M}+\mathrm{H}) 165$; HRMS (ES) (found $165.1386[\mathrm{M}+\mathrm{H}]^{+} ; \mathrm{C}_{10} \mathrm{H}_{16} \mathrm{~N}_{2}$ requires 165.1386).

## Preparation of $\mathbf{2 5 7}$

Glyoxylic acid monohydrate 255 ( $1.22 \mathrm{~g}, 13.2 \mathrm{mmol}$ ) and $L$-phenylalaninmethylamide 138 ( $1 \mathrm{~g}, 6.6 \mathrm{mmol}$ ) were dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(100 \mathrm{~mL})$ and stirred overnight at room temperature. The resulting solution was then concentrated under reduced pressure to yield the title compound ( $1.29 \mathrm{~g}, 74 \%$ ) as a colourless solid. For X-ray structure see Appendix. $\mathrm{mp} 175-177{ }^{\circ} \mathrm{C}$; $v_{\max }\left(\mathrm{CHCl}_{3}\right) / \mathrm{cm}^{-1} 3680,1664,1524,1423,1215,1017 ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{H}}$ (rotameric ratio $2.58: 1$ ) $7.93(1 \mathrm{H}, \mathrm{s}, \mathrm{NCHO}$, minor rotamer), 7.85 $(1 \mathrm{H}, \mathrm{s}, \mathrm{CHO}$, major rotamer), 7.24-7.05 $(5 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\mathrm{H}$, major and minor), $4.57(1 \mathrm{H}, \mathrm{t}, J=$ 8.4, $\mathrm{CHCH}_{2}$, minor $), 4.14\left(1 \mathrm{H}, \mathrm{dd}, J=4.5,10.9, \mathrm{CHCH}_{2}\right.$, major $) 3.96-3.65(2 \mathrm{H}, \mathrm{m}$, $\mathrm{CH}_{2} \mathrm{COOH}$, major and minor) 3.61-3.40 $\left(1 \mathrm{H}, \mathrm{m}, \mathrm{CHCH}_{2}\right.$, major) 3.27-3.24 $(1 \mathrm{H}, \mathrm{m}$, $\mathrm{CHCH}_{2}$, minor $) 300-2.95\left(1 \mathrm{H}, \mathrm{m}, \mathrm{CHCH}_{2}\right.$, minor $) 2.80-2.75\left(4 \mathrm{H}, \mathrm{m}, \mathrm{NCH}_{3}, \mathrm{CHCH}_{2}\right.$, major), $2.66-2.65\left(3 \mathrm{H}, \mathrm{m}, \mathrm{NCH}_{3}\right.$, minor) ${ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{C}} 170.8,169.5$, $169.3,163.9,163.3,136.9,136.8,129.0,128.9,128.7,127.20,126.9,64.1,52.8,52.8,47.4$, 45.2, 36.1, 34.2, 26.5, 26.3; $\mathrm{m} / \mathrm{z}$ (APCI) 264 (M+H); HRMS (EI) (found $264.1105[\mathrm{M}+\mathrm{H}]^{+}$; $\mathrm{C}_{13} \mathrm{H}_{16} \mathrm{~N}_{2} \mathrm{O}_{4}$ requires 264.1103).

## Synthesis of 2-(propylamino)acetic acid hydrochloride 273

Glyoxylic acid monohydrate 255 ( $1.71 \mathrm{~g}, 19.0 \mathrm{mmol}$ ) was dissolved in distilled water $(20 \mathrm{~mL})$ at room temperature. Phenethylamine $258(1.00 \mathrm{~g}, 8.25 \mathrm{mmol})$ was added and the resulting solution stirred for 24 hours. During this time the formation of a white precipitate
was observed. After this period $2 \mathrm{M} \mathrm{HCl}(20 \mathrm{~mL}, 40 \mathrm{mmol})$ was added and the reaction mixture heated at reflux overnight. The solvent was removed under reduced pressure and the residue recrystallised from methanol/diethyl ether to give the title compound $(1.24 \mathrm{~g}$, $70 \%$ ) as a colourless solid. $\mathrm{mp} 184{ }^{\circ} \mathrm{C} ; \mathrm{v}_{\max }(\mathrm{Nujol}) / \mathrm{cm}^{-1} 2924,1748 ;{ }^{1} \mathrm{H}$ NMR ( 500 MHz , d$6 \mathrm{DMSO}) \delta_{\mathrm{H}} 13.80\left(1 \mathrm{H}, \mathrm{bs}, \mathrm{CO}_{2} \underline{\mathrm{H}}\right) 9.38(2 \mathrm{H}, \mathrm{bs}, \mathrm{NH}), 7.36-7.24(5 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}) 3.89(2 \mathrm{H}$, s, $\left.\mathrm{NCH}_{2} \mathrm{CO}_{2} \mathrm{H}\right) 3.16\left(2 \mathrm{H}, \mathrm{t}, J=10.0, \mathrm{NCH}_{2}\right) 2.99\left(2 \mathrm{H}, \mathrm{t}, J=10.0, \mathrm{CH}_{2} \mathrm{Ar}\right) ;{ }^{13} \mathrm{C}$ NMR ( 125 MHz , d-6 DMSO) $\delta_{\mathrm{C}} 168.5$ (C) 137.6 (C) 129.1 (CH) 129.1 (CH) $127.3(\mathrm{CH}) 48.1$ $\left(\mathrm{CH}_{2}\right) 47.3\left(\mathrm{CH}_{2}\right) 31.8\left(\mathrm{CH}_{2}\right)$; MS (ES) $m / z=180[\mathrm{M}+\mathrm{H}-\mathrm{HCl}]^{+}$; HRMS (ES) (found $180.1019[\mathrm{M}+\mathrm{H}-\mathrm{HCl}]^{+} \mathrm{C}_{10} \mathrm{H}_{14} \mathrm{NO}_{2}$; requires 180.1025)

## Synthesis of 2-(propylamino)acetic acid hydrochloride 274

Glyoxylic acid monohydrate 255 ( $1.71 \mathrm{~g}, 19.0 \mathrm{mmol}$ ) was dissolved in distilled water $(20 \mathrm{~mL})$ at room temperature. Propylamine ( $0.50 \mathrm{~g}, 8.5 \mathrm{mmol}$ ) was added and the resulting solution stirred for 24 hours. After this period $2 \mathrm{M} \mathrm{HCl}(20 \mathrm{~mL}, 40 \mathrm{mmol})$ was added and the reaction mixture heated at reflux overnight. The solvent was removed under reduced pressure and the residue recrystallised from methanol / diethyl ether to give the title compound ( $1.02 \mathrm{~g}, 78 \%$ ) as a colourless solid. $\mathrm{mp} 197-198^{\circ} \mathrm{C}$; $\mathrm{v}_{\max }$ (Nujol)/ $/ \mathrm{cm}^{-1} 2924$, 1753; ${ }^{1} \mathrm{H}$ NMR ( 400 MHz , d-6 DMSO) $\delta_{\mathrm{H}} 13.73$ ( $1 \mathrm{H}, \mathrm{bs}, \mathrm{CO}_{2} \underline{\mathrm{H}}$ ), 9.18 ( $2 \mathrm{H}, \mathrm{bs}, \mathrm{NH}$ ), 3.84 $\left(2 \mathrm{H}, \mathrm{s}, \mathrm{NCH}_{2} \mathrm{CO}_{2} \mathrm{H}\right), 2.85\left(2 \mathrm{H}, \mathrm{t}, J=7.8, \mathrm{NCH}_{2}\right), 1.69-1.61\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2} \mathrm{CH}_{3}\right), 0.89(3 \mathrm{H}, \mathrm{t}$, $\left.J=7.5, \mathrm{CH}_{2} \mathrm{CH}_{3}\right) ;{ }^{13} \mathrm{C}$ NMR ( $62.5 \mathrm{MHz}, \mathrm{d}-6 \mathrm{DMSO}$ ) $\delta_{\mathrm{C}} 167.9(\mathrm{C}), 48.2\left(\mathrm{CH}_{2}\right), 46.7\left(\mathrm{CH}_{2}\right)$, 18.7 $\left(\mathrm{CH}_{2}\right), 10.9\left(\mathrm{CH}_{3}\right) . \mathrm{MS}(\mathrm{ES}) \mathrm{m} / \mathrm{z}=118[\mathrm{M}+\mathrm{H}-\mathrm{HCl}]^{+}$; HRMS (ES) 118.0868 calculated for $\mathrm{C}_{5} \mathrm{H}_{11} \mathrm{~N}_{1} \mathrm{O}_{2}[\mathrm{M}+\mathrm{H}-\mathrm{HCl}]^{+}$, found 118.0863.

Synthesis of 2-(cylohexylamino)acetic acid hydrochloride 275

$50 \%$-Glyoxylic acid solution ( $0.82 \mathrm{~g}, 11.1 \mathrm{mmol}$ ) was added to distilled water ( 20 mL ) at room temperature. Cyclohexylamine ( $0.50 \mathrm{~g}, 5.05 \mathrm{mmol}$ ) was added and the resulting solution stirred for 24 hours. The solvent was removed under reduced pressure to give a yellow oil. Then $2 \mathrm{M} \mathrm{HCl}(20 \mathrm{~mL}, 40 \mathrm{mmol})$ was added and the reaction mixture heated at reflux overnight. The solvent was removed under reduced pressure and the residue recrystallised from methanol / diethyl ether to give the title compound $(0.77 \mathrm{~g}, 86 \%)$ as a colourless solid. $\mathrm{mp} 208{ }^{\circ} \mathrm{C}$; $\mathrm{v}_{\max }(\mathrm{Nujol}) / \mathrm{cm}^{-1} 2924,1759 ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{d}-6 \mathrm{DMSO}$ ) $\delta_{\mathrm{H}} 13.77\left(1 \mathrm{H}, \mathrm{bs}, \mathrm{CO}_{2} \underline{\mathrm{H}}\right), 9.09(2 \mathrm{H}, \mathrm{bs}, \mathrm{NH}), 3.85\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{NCH}_{2} \mathrm{CO}_{2} \mathrm{H}\right), 3.03-2.90(1 \mathrm{H}, \mathrm{m}$, $\left.\mathrm{NCH}\left(\mathrm{CH}_{2}\right)_{2}\right), 2.09-1.95\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CHCH}_{2} \mathrm{CH}_{2}\right), 1.81-1.67\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CHCH}_{2} \mathrm{CH}_{2}\right), 1.63-1.53$ ( $1 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}$ ), 1.39-0.90 ( $5 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}$ ); ${ }^{13} \mathrm{C}$ NMR ( $125 \mathrm{MHz}, \mathrm{d}-6 \mathrm{DMSO}$ ) $\delta_{\mathrm{C}} 167.7(\mathrm{C})$, 57.1(CH), 44.0( $\left.\mathrm{CH}_{2}\right), 28.7\left(\mathrm{CH}_{2}\right), 24.6\left(\mathrm{CH}_{2}\right), 24.1\left(\mathrm{CH}_{2}\right) ; \mathrm{MS}(\mathrm{ES}) \mathrm{m} / \mathrm{z}=158[\mathrm{M}+\mathrm{H}-$ $\mathrm{HCl}^{+}$; HRMS (ES) 158.1181 calculated for $\mathrm{C}_{8} \mathrm{H}_{15} \mathrm{NO}_{2}[\mathrm{M}+\mathrm{H}-\mathrm{HCl}]^{+}$, found 158.1176.

Synthesis of 2-(allylamino)acetic acid hydrochloride 276

Glyoxylic acid monohydrate 255 ( $1.77 \mathrm{~g}, 19.3 \mathrm{mmol}$ ) was dissolved in distilled water $(20 \mathrm{~mL})$ at room temperature. Allylamine ( $0.50 \mathrm{~g}, 8.76 \mathrm{mmol}$ ) was added and the resulting solution stirred for 24 hours. After this period $2 \mathrm{M} \mathrm{HCl}(20 \mathrm{~mL}, 40 \mathrm{mmol})$ was added and the reaction mixture heated at reflux overnight. The solvent was removed under reduced pressure and the crude product dissolved in methanol and filtered through Celite ${ }^{\circledR}$. The residue was recrystallised from methanol/diethyl ether to give the title compound $(0.33 \mathrm{~g}$, $25 \%$ ) as a brownish solid. $\mathrm{mp} 163-164{ }^{\circ} \mathrm{C} ; \mathrm{v}_{\max }$ (Nujol)/ $\mathrm{cm}^{-1} 2912,1752 ;{ }^{1} \mathrm{H}$ NMR $(400 \mathrm{MHz}, \mathrm{MeOD}) \delta_{\mathrm{H}} 6.01-5.87\left(1 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}=\mathrm{CH}\right), 5.56\left(1 \mathrm{H}, \mathrm{dd}, J=17.1,0.9, \mathrm{CH}_{2}=\mathrm{CH}\right)$, $5.52\left(1 \mathrm{H}, \mathrm{dd}, J=10.1,0.8, \mathrm{CH}_{2}=\mathrm{CH}\right), 3.89\left(2 \mathrm{H}, \mathrm{s}, \mathrm{NCH}_{2} \mathrm{CO}_{2} \mathrm{H}\right), 3.71(2 \mathrm{H}, \mathrm{d}, J=7.7$,
$\left.\mathrm{NCH}_{2}\right) ;{ }^{13} \mathrm{C}$ NMR ( $\left.62.5 \mathrm{MHz}, \mathrm{MeOD}\right) \delta_{\mathrm{C}} 167.5(\mathrm{C}), 127.5(\mathrm{CH}), 123.4\left(\mathrm{CH}_{2}\right), 49.11\left(\mathrm{CH}_{2}\right)$, 46.1 $\left(\mathrm{CH}_{2}\right) ; \mathrm{MS}(\mathrm{ES}) \mathrm{m} / \mathrm{z}=116[\mathrm{M}+\mathrm{H}-\mathrm{HCl}]^{+} ; \mathrm{HRMS}(\mathrm{ES}) 116.0712$ calculated for $\mathrm{C}_{5} \mathrm{H}_{9} \mathrm{NO}_{2}\left[\mathrm{M}+\mathrm{H}-\mathrm{HCl}^{+}\right.$, found 116.0706.

## Synthesis of 2-(benzylamino)acetic acid hydrochloride 277

Glyoxylic acid monohydrate $255(0.95 \mathrm{~g}, 10.3 \mathrm{mmol})$ was dissolved in distilled water $(20 \mathrm{~mL})$ at room temperature. Benzylamine ( $0.50 \mathrm{~g}, 4.67 \mathrm{mmol}$ ) was added and the resulting solution stirred for 24 hours. The solvent was removed under reduced pressure to give a yellow oil. Then $1 \mathrm{NHCl}(20 \mathrm{~mL}, 20 \mathrm{mmol})$ was added and the reaction mixture heated at reflux overnight. The solvent was removed under reduced pressure and the residue recrystallised from methanol / diethyl ether to give the title compound $(0.47 \mathrm{~g}, 50 \%)$ as a colourless solid. mp 221-222 ${ }^{\circ} \mathrm{C} ; \mathrm{v}_{\max }$ (Nujol)/ $\mathrm{cm}^{-1} 2924,1747 ;{ }^{1} \mathrm{H}$ NMR (400MHz, MeOD) $\delta_{\mathrm{H}} 7.54-7.42(5 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}), 4.26\left(2 \mathrm{H}, \mathrm{s}, \mathrm{NCH}_{2} \mathrm{CO}_{2} \mathrm{H}\right), 3.92\left(2 \mathrm{H}, \mathrm{s}, \mathrm{NCH}_{2} \mathrm{Ar}\right) ;{ }^{13} \mathrm{C}$ NMR $(125 \mathrm{MHz}, \mathrm{MeOD}) \delta_{\mathrm{C}} 167.3(\mathrm{C}), 130.8(\mathrm{C}), 129.7(\mathrm{CH}), 129.5(\mathrm{CH}), 129.0(\mathrm{CH}), 50.6\left(\mathrm{CH}_{2}\right)$, $46.2\left(\mathrm{CH}_{2}\right) ; \mathrm{MS}(\mathrm{ES}) m / z=166[\mathrm{M}+\mathrm{H}-\mathrm{HCl}]^{+} ; \mathrm{HRMS}(\mathrm{ES}) 166.0868$ calculated for $\mathrm{C}_{9} \mathrm{H}_{11} \mathrm{NO}_{2}[\mathrm{M}+\mathrm{H}-\mathrm{HCl}]^{+}$, found 166.0863.

## Synthesis of 2-(4-methoxybenzylamino)acetic acid hydrochloride 278

$50 \%$-Glyoxylic acid solution ( $0.59 \mathrm{~g}, 7.97 \mathrm{mmol}$ ) was added to distilled water ( 20 mL ) at room temperature. 4-Methoxybenzylamine ( $0.50 \mathrm{~g}, 3.64 \mathrm{mmol}$ ) was added and the resulting solution stirred for 24 hours at $50^{\circ} \mathrm{C}$. The solvent was removed under reduced pressure to give a yellow oil. Then $2 \mathrm{M} \mathrm{HCl}(20 \mathrm{~mL}, 40 \mathrm{mmol})$ was added and the reaction mixture heated at reflux overnight. The solvent was removed under reduced pressure and the residue recrystallised from methanol / diethyl ether to give the title compound $(0.57 \mathrm{~g}, 68 \%)$
as a colourless solid. $\mathrm{mp} 200^{\circ} \mathrm{C} ; \mathrm{v}_{\max }$ (Nujol)/ $/ \mathrm{cm}^{-1}$ 2924, $1745 ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{MeOD}$ ) $\delta_{\mathrm{H}} 7.45-7.38$ ( $2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}$ ), 7.04-6.97 ( $2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}$ ), 4.19 ( $2 \mathrm{H}, \mathrm{s}$, $\left.\mathrm{NCH}_{2} \mathrm{CO}_{2} \mathrm{H}\right), 3.88\left(2 \mathrm{H}, \mathrm{s}, \mathrm{NCH}_{2} \mathrm{Ar}\right), 3.83\left(3 \mathrm{H}, \mathrm{s}, \mathrm{OC} \underline{H}_{3}\right) ;{ }^{13} \mathrm{C}$ NMR ( $125 \mathrm{MHz}, \mathrm{d}-6 \mathrm{DMSO}$ ) $\delta_{\mathrm{C}} 168.2(\mathrm{C}), 160.2(\mathrm{C}), 132.3(\mathrm{CH}), 123.8(\mathrm{C}), 114.5(\mathrm{CH}), 55.7\left(\mathrm{CH}_{3}\right), 49.7\left(\mathrm{CH}_{2}\right), 46.4\left(\mathrm{CH}_{2}\right)$; MS (ES) $m / z=196[\mathrm{M}+\mathrm{H}-\mathrm{HCl}]^{+}$; HRMS (ES) 196.0974 calculated for $\mathrm{C}_{10} \mathrm{H}_{13} \mathrm{NO}_{2}[\mathrm{M}+$ $\mathrm{H}-\mathrm{HCl}]^{+}$, found 196.0968 .

## Synthesis of 2-(4-chlorobenzylamino)acetic acid hydrochloride 279

$50 \%$-Glyoxylic acid solution ( $0.58 \mathrm{~g}, 7.83 \mathrm{mmol}$ ) was added to distilled water $(20 \mathrm{~mL})$ at room temperature. 4-Chlorobenzylamine ( $0.50 \mathrm{~g}, 3.53 \mathrm{mmol}$ ) was added and the resulting solution stirred for 24 hours at $50^{\circ} \mathrm{C}$. The solvent was removed under reduced pressure to give a yellow oil. Then $2 \mathrm{M} \mathrm{HCl}(20 \mathrm{~mL}, 40 \mathrm{mmol})$ was added and the reaction mixture heated at reflux overnight. The solvent was removed under reduced pressure and the residue recrystallised from methanol/diethyl ether to give the title compound $(0.50 \mathrm{~g}, 60 \%)$ as a colourless solid. mp $216-217^{\circ} \mathrm{C} ; \quad \mathrm{v}_{\max } \quad$ (Nujol)/ $/ \mathrm{cm}^{-1} \quad 2925, \quad 1745 ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{MeOD}$ ) $\delta_{\mathrm{H}}$ 7.57-7.41 ( $4 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}$ ), 4.26 (s, $2 \mathrm{H}, \mathrm{NCH}_{2} \mathrm{CO}_{2} \mathrm{H}$ ), 3.94 (s, 2 H , $\left.\mathrm{NCH}_{2} \mathrm{Ar}\right) ;{ }^{13} \mathrm{C}$ NMR ( $125 \mathrm{MHz}, \mathrm{MeOD}$ ) $\delta_{\mathrm{C}} 167.3(\mathrm{C}), 135.5(\mathrm{C}), 131.6(\mathrm{CH}), 129.5(\mathrm{C})$, $129.0(\mathrm{CH}), 49.9\left(\mathrm{CH}_{2}\right), 46.3\left(\mathrm{CH}_{2}\right) ; \mathrm{MS}(\mathrm{ES}) \mathrm{m} / \mathrm{z}=200[\mathrm{M}+\mathrm{H}-\mathrm{HCl}]^{+} ;$HRMS (ES) 200.0478 calculated for $\mathrm{C}_{9} \mathrm{H}_{10} \mathrm{ClNO}_{2}[\mathrm{M}+\mathrm{H}-\mathrm{HCl}]^{+}$, found 200.0473.

Synthesis of 2-(2-aminoethylamino) acetic acid dihydrochloride 284

Glyoxylic acid monohydrate $255(3.37 \mathrm{~g}, 36.6 \mathrm{mmol})$ was dissolved in water ( 20 mL ) at room temperature. Ethylenediamine ( $0.50 \mathrm{~g}, 8.32 \mathrm{mmol}$ ) was added and the resulting solution stirred for 24 hours. After that period $2 \mathrm{M} \mathrm{HCl}(20 \mathrm{~mL}, 40 \mathrm{mmol})$ was added and
the reaction mixture heated at reflux overnight. The solvent was removed under reduced pressure and the residue recrystallised from methanol/diethyl ether to give the title compound ( $0.49 \mathrm{~g}, 31 \%$ ) as a colourless solid. $v_{\max }$ (Nujol) 2923, $1719 \mathrm{~cm}^{-1} ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{d}-6 \mathrm{DMSO}$ ) $\delta_{\mathrm{H}} 8.39$ (bs, $4 \mathrm{H}, \mathrm{NH}$ ), 4.03 (s, $2 \mathrm{H}, \mathrm{NCH}_{2} \mathrm{CO}_{2} \mathrm{H}$ ), $3.46-3.39(\mathrm{~m}, 2 \mathrm{H}$, $\mathrm{NCH}_{2}$ ), 3.38-3.32 (m, 2H, $\mathrm{NCH}_{2}$ ); ${ }^{13} \mathrm{C}$ NMR ( $125 \mathrm{MHz}, \mathrm{d}-6 \mathrm{DMSO}$ ) $\delta_{\mathrm{C}} 168.2(\mathrm{C})$, $47.4\left(\mathrm{CH}_{2}\right)$, $44.3\left(\mathrm{CH}_{2}\right), 35.5\left(\mathrm{CH}_{2}\right)$;

## Synthesis of 2-(2-(dimethylamino)ethylamino)acetic acid dihydrochloride 288

Glyoxylic acid monohydrate $255(1.15 \mathrm{~g}, 12.5 \mathrm{mmol})$ was dissolved in water ( 20 mL ) at room temperature. $N, N$-Dimethylethylenediamine $(0.50 \mathrm{~g}, 5.67 \mathrm{mmol})$ was added and the resulting solution stirred for 24 hours. After that period $2 \mathrm{M} \mathrm{HCl}(20 \mathrm{~mL}, 40 \mathrm{mmol})$ was added and the reaction mixture heated at reflux overnight. The solvent was removed under reduced pressure and the residue recrystallised from methanol/diethyl ether to give the title compound ( $0.71 \mathrm{~g}, 57 \%$ ) as a colourless solid. $\mathrm{mp} 202{ }^{\circ} \mathrm{C}$; $\mathrm{v}_{\max }(\mathrm{Nujol}) / \mathrm{cm}^{-1} 2924,1718 ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{MeOD}$ ) $\delta_{\mathrm{H}} 4.05\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{NCH}_{2} \mathrm{CO}_{2} \mathrm{H}\right), 3.62-3.52\left(\mathrm{~m}, 4 \mathrm{H}, \mathrm{NCH}_{2}\right), 2.99(\mathrm{~s}$, $\left.6 \mathrm{H}, \mathrm{NCH}_{2}\right) ;{ }^{13} \mathrm{C}$ NMR ( $125 \mathrm{MHz}, \mathrm{d}-6 \mathrm{DMSO}$ ) $\delta_{\mathrm{C}} 168.0(\mathrm{C}), 52.5\left(\mathrm{CH}_{2}\right), 47.3\left(\mathrm{CH}_{2}\right)$, $42.9\left(\mathrm{CH}_{3}\right), 41.4\left(\mathrm{CH}_{2}\right) ; \mathrm{MS}(\mathrm{ES}) \mathrm{m} / \mathrm{z}=147[\mathrm{M}+\mathrm{H}-2 \mathrm{HCl}]^{+}$. HRMS (ES) 147.1134 calculated for $\mathrm{C}_{6} \mathrm{H}_{14} \mathrm{~N}_{2} \mathrm{O}_{2}[\mathrm{M}+\mathrm{H}-2 \mathrm{HCl}]^{+}$, found 147.1128.

## Synthesis of 2-(2-(methylamino)ethylamino)acetic acid dihydrochloride 287

Glyoxylic acid monohydrate $255(1.37 \mathrm{~g}, 14.9 \mathrm{mmol})$ was dissolved in water ( 20 mL ) at room temperature. $N$-Methylethylenediamine $(0.50 \mathrm{~g}, 6.75 \mathrm{mmol})$ was added and the resulting solution stirred for 24 hours. The solvent was removed under reduced pressure to give a brown oil. Then $2 \mathrm{M} \mathrm{HCl}(30 \mathrm{~mL}, 60 \mathrm{mmol})$ was added and the reaction mixture $\mathrm{MHz}, \mathrm{d}-6 \mathrm{DMSO}) \delta_{\mathrm{C}} 168.2(\mathrm{C}), 47.3\left(\mathrm{CH}_{2}\right), 44.3\left(\mathrm{CH}_{2}\right), 42.9\left(\mathrm{CH}_{2}\right), 32.7\left(\mathrm{CH}_{3}\right)$.

## Synthesis of 2-(3-(dimethylamino)propylamino)acetic acid dihydrochloride 290

Glyoxylic acid monohydrate $255(1.98 \mathrm{~g}, 21.5 \mathrm{mmol})$ was dissolved in water ( 20 mL ) at room temperature. 3-Dimethylaminopropylamine ( $0.50 \mathrm{~g}, 4.89 \mathrm{mmol}$ ) was added and the resulting solution stirred for 24 hours. The solvent was removed under reduced pressure to give a brown oil. Then $2 \mathrm{M} \mathrm{HCl}(25 \mathrm{~mL}, 50 \mathrm{mmol})$ was added and the reaction mixture heated at reflux overnight. The solvent was removed under reduced pressure and the residue recrystallised from methanol/diethyl ether to give the title compound $(0.57 \mathrm{~g}, 50 \%)$ as a colourless solid. $\mathrm{mp} 194{ }^{\circ} \mathrm{C}$; $v_{\max }$ (Nujol)/ $\mathrm{cm}^{-1} 2924,1754 ;{ }^{1} \mathrm{H} \mathrm{NMR}(400 \mathrm{MHz}, \mathrm{MeOD}) \delta_{\mathrm{H}}$ $3.99\left(2 \mathrm{H}, \mathrm{s}, \mathrm{NCH}_{2} \mathrm{CO}_{2} \mathrm{H}\right), 3.26\left(2 \mathrm{H}, \mathrm{t}, J=7.9, \mathrm{NCH}_{2}\right), 3.19\left(2 \mathrm{H}, \mathrm{t}, J=8.0, \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{~N}\right), 2.93$ $\left(6 \mathrm{H}, \mathrm{s}, \mathrm{NCH}_{3}\right), 2.27-2.12\left(2 \mathrm{H}, \mathrm{m},\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NCH}_{2}\right) .{ }^{13} \mathrm{C} \mathrm{NMR}(125 \mathrm{MHz}, \mathrm{d}-6 \mathrm{DMSO}) \delta_{\mathrm{C}}$ 168.2(C), 53.8( $\left.\mathrm{CH}_{2}\right), 47.2\left(\mathrm{CH}_{2}\right), 44.3\left(\mathrm{CH}_{2}\right), 42.3\left(\mathrm{CH}_{3}\right), 20.8\left(\mathrm{CH}_{2}\right) . \mathrm{MS}(\mathrm{ES}) m / z=161[\mathrm{M}$ $+\mathrm{H}-2 \mathrm{HCl}]^{+}$. ## Synthesis of 5-methoxy-3-(1-(5-methoxy-1H-indol-3-yl)propyl)-1H-indole 310

5-Methoxyindole 306 ( $200 \mathrm{mg}, 1.35 \mathrm{mmol}$ ) was added to methanol ( 2.5 mL ) and benzoic acid $N^{\prime}$-isopropylhyrdazide $91(14.5 \mathrm{mg}, 0.0675 \mathrm{mmol}, 0.1 \mathrm{eq})$ and stirred at $25{ }^{\circ} \mathrm{C}$. Propionaldehyde 304 ( $39 \mathrm{mg}, 0.675 \mathrm{mmol}, 0.049 \mathrm{~mL}$,) was added, the reaction tube sealed and allowed to stir for 24 hrs at ambient temperature. The solvent was removed under reduced pressure and the resulting mixture was then purified by flash column chromatography eluting with $3: 1$ petroleum ether/ethyl acetate to yield the title compound ( $124 \mathrm{mg}, 55 \%$ ) as an off white solid. $\mathrm{mp} 70-72^{\circ} \mathrm{C}$; $v_{\max }$ (nujol) $/ \mathrm{cm}^{-1} 3403,2360,1622$, $1579,1483,1435,1288,1208,1171,1096 \mathrm{~cm}^{-1} ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $7.81(2 \mathrm{H}, \mathrm{bs}$, NH) $7.24(2 \mathrm{H}, \mathrm{d}, \mathrm{Ar} \underline{\mathrm{H}}, J=9.04) 7.02(2 \mathrm{H}, \mathrm{dd},, J=13.1,2.5, \mathrm{Ar}-\underline{\mathrm{H}}) 6.83(2 \mathrm{H}, \mathrm{dd}, \mathrm{Ar} \underline{\mathrm{H}}, J=$ $8.5,2.51), 4.27(1 \mathrm{H}, \mathrm{t}, J=7.5, \mathrm{CH}), 3.76\left(6 \mathrm{H}, \mathrm{s}, \mathrm{OCH}_{3}\right), 2.23\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right) 1.01(3 \mathrm{H}, \mathrm{t}, J=$ $\left.7.5, \mathrm{CH}_{3}\right) ;{ }^{13} \mathrm{C} \mathrm{NMR}\left(100 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 154.4(\mathrm{C}), 131.8(\mathrm{C}), 127.5(\mathrm{C}), 122.1(\mathrm{CH})$, $120.0(\mathrm{C}), 111.6(\mathrm{CH}), 101.8(\mathrm{CH}), 55.9\left(\mathrm{CH}_{3}\right), 35.8(\mathrm{CH}), 28.2\left(\mathrm{CH}_{2}\right), 13.1\left(\mathrm{CH}_{3}\right) . \mathrm{m} / \mathrm{z}(\mathrm{APCI})$ $335(\mathrm{M}+\mathrm{H})$; HRMS (ES) (found $335.1752[\mathrm{M}+\mathrm{H}]^{+} ; \mathrm{C}_{21} \mathrm{H}_{22} \mathrm{~N}_{2} \mathrm{O}_{2}$ requires 335.1754 ).

## Synthesis of 3-(1-(1H-indol-3-yl)propyl)-1H-indole 305

Indole $300(158 \mathrm{mg}, 1.35 \mathrm{mmol})$ was added to methanol ( 2.5 mL ) and benzoic acid $N^{\prime}$ isopropylhyrdazide 91 ( $14.5 \mathrm{mg}, 0.0675 \mathrm{mmol}, 0.1 \mathrm{eq}$ ) and stirred at $25^{\circ} \mathrm{C}$. Propionaldehyde 304 ( $39 \mathrm{mg}, 0.675 \mathrm{mmol}, 0.049 \mathrm{~mL}$,) was added, the reaction tube sealed and allowed to stir for 24 hrs at ambient temperature. The solvent was removed under reduced pressure and the resulting mixture was then purified by flash column chromatography eluting with $3: 1$ petroleum ether/ethyl acetate to yield the title compound ( $156 \mathrm{mg}, 84 \%$ ) as an off white solid. mp 131-133 ${ }^{\circ} \mathrm{C}$; $v_{\text {max }}\left(\mathrm{CHCl}_{3}\right) / \mathrm{cm}^{-1} 3478,3418,3058,3047,2962,2931,2872,1731$, $1618,1456,1447 ;{ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}} 7.89(2 \mathrm{H}, \mathrm{bs}, \mathrm{NH}), 7.60(2 \mathrm{H}, \mathrm{d}, J=7.7$, Ar-H), 7.53-7.00 ( $8 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\mathrm{H}$ ), $4.39\left(1 \mathrm{H}, \mathrm{t}, J=7.4, \mathrm{CHCH}_{2}\right), 2.30-2.22\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2} \mathrm{CH}_{3}\right)$, $1.02\left(3 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.4, \mathrm{CH}_{2} \mathrm{CH}_{3}\right) ;{ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{C}} \quad 136.6(\mathrm{C}), 127.2(\mathrm{C})$, $121.7(\mathrm{CH}), 121.5(\mathrm{CH}), 120.3(\mathrm{C}), 119.7(\mathrm{CH}), 119.0(\mathrm{CH}), 111.1(\mathrm{CH}), 35.9(\mathrm{CH}), 28.7\left(\mathrm{CH}_{2}\right)$, 13.1( $\left.\mathrm{CH}_{3}\right)$.

## Synthesis of 5-chloro-3-(1-(5-chloro-1H-indol-3-yl)propyl)-1H-indole 311

5-Chloroindole 307 ( $200 \mathrm{mg}, 1.32 \mathrm{mmol}$ ) was added to methanol ( 3.0 mL ) and benzoic acid $N^{\prime}$-isopropylhyrdazide 91 ( $14.1 \mathrm{mg}, 0.066 \mathrm{mmol}, 0.1 \mathrm{eq}$ ) and stirred at $25{ }^{\circ} \mathrm{C}$. Propionaldehyde 304 ( $39 \mathrm{mg}, 0.660 \mathrm{mmol}, 0.05 \mathrm{~mL}$,) was added, the reaction tube sealed and allowed to stir for 24 hrs at ambient temperature. The solvent was removed under reduced pressure and the resulting mixture was then purified by flash column chromatography eluting with $3: 1$ petroleum ether/ethyl acetate to yield the title compound $(190 \mathrm{mg}, 42 \%)$ as an off white solid. $\mathrm{mp} 88{ }^{\circ} \mathrm{C} ; ;{ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}} 7.98(2 \mathrm{H}$,

## Synthesis of 1-methyl-3-(1-(1-methyl-1H-indol-3-yl)propyl)-1H-indole

$N$-Methylindole 291 ( $177 \mathrm{mg}, 1.35 \mathrm{mmol}$ ) was added to methanol ( 2.5 mL ) and benzoic acid $N^{\prime}$-isopropylhyrdazide $91(14.5 \mathrm{mg}, 0.0675 \mathrm{mmol}, 0.1 \mathrm{eq})$ and stirred at $25{ }^{\circ} \mathrm{C}$. Propionaldehyde 304 ( $39 \mathrm{mg}, 0.675 \mathrm{mmol}, 0.049 \mathrm{~mL}$,) was added and allowed to stir for 24 hrs at ambient temperature. The solvent was removed under reduced pressure and the resulting mixture was then purified by flash column chromatography eluting with $10: 1$ petroleum ether/ethyl acetate to yield the title compound ( $165 \mathrm{mg}, 81 \%$ ) as an off white solid. mp 142-144 ${ }^{\circ} \mathrm{C} ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{OD}$ ) $\delta_{\mathrm{H}} 7.46(2 \mathrm{H}, \mathrm{d}, J=8.0, \mathrm{Ar}-\underline{\mathrm{H}}), 7.11$ ( $2 \mathrm{H}, \mathrm{d}, J=8.2, \mathrm{Ar}-\underline{\mathrm{H}}$ ), 7.05-7.03 ( $2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}$ ), $6.90-6.88$ ( $2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\mathrm{H}$ ), 6.68 ( $2 \mathrm{H}, \mathrm{s}, \mathrm{Ar}-$ $\underline{\mathrm{H}}), 4.21\left(1 \mathrm{H}, \mathrm{t}, J=7.4, \mathrm{CHCH}_{2}\right), 3.53\left(6 \mathrm{H}, \mathrm{s}, \mathrm{NCH}_{3}\right) 2.09-2.09\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CHCH}_{2} \mathrm{CH}_{3}\right), 0.85$ $\left(3 \mathrm{H}, \mathrm{t}, J=7.4, \mathrm{CH}_{2} \mathrm{CH}_{3}\right)$.

## Synthesis of 3-(cyclopropyl(1H-indol-3-yl)methyl)-1H-indole 293

$N$-Methyl indole 291 ( $177 \mathrm{mg}, 1.35 \mathrm{mmol}$ ) was added to methanol ( 2.5 mL ) and benzoic acid $N^{\prime}$-isopropylhyrdazide $91(14.5 \mathrm{mg}, 0.0675 \mathrm{mmol}, 0.1 \mathrm{eq})$ and stirred at $25{ }^{\circ} \mathrm{C}$. cyclopropanecarboxaldehyde $292(47 \mathrm{mg}, 0.675 \mathrm{mmol})$ was added, the reaction tube sealed and allowed to stir for 24 hrs at ambient temperature. The solvent was removed under reduced pressure and the resulting mixture was then purified by flash column chromatography eluting with 3:1 petroleum ether/ethyl acetate to yield the title compound
( $157 \mathrm{mg}, 74 \%$ ) as an off white solid. $\mathrm{mp} 124-125^{\circ} \mathrm{C} ; v_{\max }\left(\mathrm{CHCl}_{3}\right) / \mathrm{cm}^{-1} 2359,1734,1473$, $1423,1372,1327 ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{H}} 7.35(2 \mathrm{H}, \mathrm{d}, \mathrm{J}=7.6, \mathrm{Ar}-\underline{\mathrm{H}}), 7.06(2 \mathrm{H}, \mathrm{d}, \mathrm{J}$ $=7.7, \operatorname{Ar}-\underline{H}), 6.97-6.93(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}), 6.78-6.73(4 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}), 3.75(1 \mathrm{H}, \mathrm{d}, J=8.4$, $\left.\mathrm{CHCH}(\mathrm{Ar})_{2}\right), 3.51\left(6 \mathrm{H}, \mathrm{s}, \mathrm{NCH}_{3}\right), 1.30-1.26\left(1 \mathrm{H}, \mathrm{m}, \mathrm{CHCH}(\mathrm{CH})_{2}\right), 0.41-0.36(2 \mathrm{H}, \mathrm{m}$, $\mathrm{CH}_{2} \mathrm{CH}_{2}$ ) $0.17-0.05$, ( $2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2} \mathrm{CH}_{2}$ ); ${ }^{13} \mathrm{C}$ NMR $\left(100 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{C}} 137.2$ (C), 127.7 (C), $126.7(\mathrm{CH}), 121.2(\mathrm{CH}), 120.0(\mathrm{CH}), 118.7(\mathrm{C}), 118.4(\mathrm{CH}), 109.0(\mathrm{CH}), 38.0(\mathrm{CH})$, $32.7\left(\mathrm{CH}_{3}\right), 17.2(\mathrm{CH}), 4.95\left(\mathrm{CH}_{2}\right)$.

## Synthesis of 3-(cyclopropyl(1-methyl-1H-indol-3-yl)methyl)-1-methyl-1H-indole 323

$N$-methyl indole 291 ( $0.52 \mathrm{~g}, 4.0 \mathrm{mmol}$, 2eq) was added to methanol ( 4 mL ) and benzoic acid $N^{\prime}$-isopropylhyrdazide 91 ( $43 \mathrm{mg}, 0.2 \mathrm{mmol}, 0.1 \mathrm{eq}$ ) and stirred at $25^{\circ} \mathrm{C}$. Cyclopropyl methyl ketone 317 ( $170 \mathrm{mg}, 2.0 \mathrm{mmol}, 0.2 \mathrm{~mL}$ ) was added, the reaction tube sealed and allowed to stir for 24 hrs at ambient temperature. The solvent was removed under reduced pressure and the resulting mixture was then purified by flash column chromatography eluting with 3:1 petroleum ether/ethyl acetate to yield the title compound ( $453 \mathrm{mg}, 69 \%$ ) as an off white solid. $\mathrm{mp} 59^{\circ} \mathrm{C}$; $v_{\text {max }}\left(\mathrm{CHCl}_{3}\right) / \mathrm{cm}^{-1} 3416,3049,3006,2935,2821,1681,1631$ $1465,1372,1323,1215,1095,1016 ;{ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}} 7.19-7.15(4 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-$ $\underline{H}), 7.02-6.98(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}), 6.93(2 \mathrm{H}, \mathrm{s}, \mathrm{Ar}-\underline{\mathrm{H}}), 6.74-6.70(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}), 3.70(6 \mathrm{H}, \mathrm{s}$, $\left.\mathrm{NCH}_{3}\right), 1.67-1.64\left(4 \mathrm{H}, \mathrm{m}, \mathrm{C} \underline{\mathrm{H}}\left(\mathrm{CH}_{2}\right)_{2}, \mathrm{CH}_{3}\right), 0.41-0.38\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right) 0.24-0.23(2 \mathrm{H}, \mathrm{m}$, $\left.\mathrm{CH}_{2}\right) ; m / z(\mathrm{APCI})(\mathrm{M}+\mathrm{H}) 328$;

## Synthesis of 3-((1H-indol-3-yl)(phenyl)methyl)-1H-indole 315

Indole $\mathbf{3 0 0}\left(500 \mathrm{mg}, 4.27 \mathrm{mmol}\right.$, 2eq) was added to methanol ( 5 mL ) and benzoic acid $N^{\prime}$ isopropylhyrdazide $91(46 \mathrm{mg}, 0.214 \mathrm{mmol}, 0.1 \mathrm{eq})$ and stirred at $25^{\circ} \mathrm{C}$. Benzaldehyde 312 ( $230 \mathrm{mg}, 2.14 \mathrm{mmol}, 0.22 \mathrm{~mL}$,) was added, the reaction tube sealed and allowed to stir for 24 hrs at ambient temperature. The solvent was removed under reduced pressure and the resulting mixture was then purified by flash column chromatography eluting with $3: 1$ petroleum ether/ethyl acetate to yield the title compound ( $570 \mathrm{mg}, 84 \%$ ) as a red solid. Measured data is consistent with literature values. ${ }^{171} \mathrm{mp} 157{ }^{\circ} \mathrm{C}$; $v_{\max }(\mathrm{KBr}) / \mathrm{cm}^{-1} ; 3416$, $1634,1378,737 .{ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}} 7.88(2 \mathrm{H}, \mathrm{bs}, \mathrm{NH}), 7.42-7.14(11 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-$ $\mathrm{H}), 7.04-6.98(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\mathrm{H}), 6.65(2 \mathrm{H}, \mathrm{d}, J=2.4, \mathrm{Ar}-\mathrm{H}), 5.89\left(1 \mathrm{H}, \mathrm{s},(\mathrm{Ar})_{3} \mathrm{CH}\right){ }^{13} \mathrm{C}$ NMR ( $125 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{C}} 145.5(\mathrm{C}), 137.0(\mathrm{C}), 128.8(\mathrm{CH}), 128.5(\mathrm{CH}), 127.1(\mathrm{C}), 126.3(\mathrm{CH})$, $124.0(\mathrm{CH}), 121.3(\mathrm{CH}) 119.6(\mathrm{CH}), 118.6(\mathrm{CH}), 118.5(\mathrm{C}), 111.9(\mathrm{CH}), 40.2(\mathrm{CH}) ; \mathrm{m} / \mathrm{z}$ (APCI) $\left(\mathrm{M}+\mathrm{H}^{+}\right) 321$.

## Synthesis of 4-(di(1H-indol-3-yl)methyl)phenol 316

Indole $300(250 \mathrm{mg}, 2.13 \mathrm{mmol}, 2 \mathrm{eq})$ was added to methanol ( 2.5 mL ) and benzoic acid $N^{\prime}$ isopropylhyrdazide 91 ( $14.5 \mathrm{mg}, 0.0675 \mathrm{mmol}, 0.1 \mathrm{eq}$ ) and stirred at $25^{\circ} \mathrm{C}$. $p$-Hydroxy benzaldehyde 313 ( $130 \mathrm{mg}, 1.07 \mathrm{mmol}$ ) was added, the reaction tube sealed and allowed to stir for 24 hrs at ambient temperature. The solvent was removed under reduced pressure and the resulting mixture was then purified by flash column chromatography eluting with (2:1) petroleum ether/ethyl acetate to yield the title compound ( $322 \mathrm{mg}, 89 \%$ ) as an off white solid. mp 118-122 ${ }^{\circ} \mathrm{C} ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{H}} 7.82(2 \mathrm{H}, \mathrm{bs}, \mathrm{NH}), 7.40-7.35(4 \mathrm{H}, \mathrm{m}$,

Ar- $\underline{H}$ ), 7.21-7.15 ( $4 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}), 7.00(2 \mathrm{H}, \mathrm{t}, J=7.8, \mathrm{Ar} \underline{\mathrm{H}}), 6.75(2 \mathrm{H}, \mathrm{d}, J=8.5, \mathrm{Ar} \underline{\mathrm{H}})$, $6.66(2 \mathrm{H}, \mathrm{d}, J=1.5, \mathrm{Ar}-\underline{\mathrm{H}}), 5.82(1 \mathrm{H}, \mathrm{s}, \mathrm{CH}), 4.67(1 \mathrm{H}, \mathrm{bs}, \mathrm{OH}) .{ }^{13} \mathrm{C}$ NMR ( 100 MHz , $\left.\mathrm{CDCl}_{3}\right) \delta_{\mathrm{C}} 129.8(\mathrm{CH}), 123.5(\mathrm{CH}), 121.9(\mathrm{CH}), 120.0(\mathrm{CH}), 119.2(\mathrm{CH}), 115.0(\mathrm{CH}), 31.0$ $(\mathrm{CH})$. None of the quaternary carbons were observed; $m / z(\mathrm{APCI})(\mathrm{M}+\mathrm{H})^{+} 339$.

Synthesis of 3-(1-(1H-indol-3-yl)cyclohexyl)-1H-indole 320

Indole $\mathbf{3 0 0}$ ( $500 \mathrm{mg}, 4.27 \mathrm{mmol}$, 2eq) was added to methanol ( 5.0 mL ) and benzoic acid $N^{\prime}$ isopropylhyrdazide $91(45.9 \mathrm{mg}, 0.214 \mathrm{mmol}, 0.1 \mathrm{eq})$ and stirred at $25^{\circ} \mathrm{C}$. Cyclohexanone 318 ( $210 \mathrm{mg}, 2.14 \mathrm{mmol}, 0.22 \mathrm{~mL}$,) was added, the reaction tube sealed and allowed to stir for 24 hrs at ambient temperature. The solvent was removed under reduced pressure and the resulting mixture was then purified by flash column chromatography eluting with $3: 1$ petroleum ether/ethyl acetate to yield the title compound ( $393 \mathrm{mg}, 59 \%$ ) as an off white solid. $\mathrm{mp} 146^{\circ} \mathrm{C}$; $v_{\max }\left(\mathrm{CHCl}_{3}\right) / \mathrm{cm}^{-1} 3477,3018,2934,2856,2356,1456,1415,1215$, $1100 ;{ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}} 7.92(2 \mathrm{H}, \mathrm{bs}, \mathrm{NH}), 7.56(2 \mathrm{H}, \mathrm{d}, J=8.0, \mathrm{Ar}-\underline{\mathrm{H}}), 7.31$ ( $2 \mathrm{H}, \mathrm{d}, J=8.1, \mathrm{Ar}-\underline{\mathrm{H}}$ ), 7.11, ( $2 \mathrm{H}, \mathrm{d}, J=2.4, \mathrm{Ar}-\underline{\mathrm{H}}$ ), $7.04(2 \mathrm{H}, \mathrm{t}, J=7.6, \mathrm{Ar}-\underline{\mathrm{H}}), 6.89(2 \mathrm{H}, \mathrm{t}, J$ $=7.9, \mathrm{Ar}-\underline{\mathrm{H}}), 2.56-2.52\left(4 \mathrm{H}, \mathrm{m}, \mathrm{CCH}_{2}\right), 1.66-1.57\left(6 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right){ }^{13} \mathrm{C} \mathrm{NMR}(100 \mathrm{MHz}$, $\left.\mathrm{CDCl}_{3}\right) \delta_{\mathrm{C}} 137.0(\mathrm{C}), 126.2(\mathrm{C}), 123.6(\mathrm{C}), 122.0(\mathrm{CH}), 121.4(\mathrm{CH}), 121.2(\mathrm{CH}), 118.5(\mathrm{CH})$, $111.0(\mathrm{CH}), 39.5(\mathrm{C}), 36.8\left(\mathrm{CH}_{2}\right), 26.8\left(\mathrm{CH}_{2}\right) 23.0\left(\mathrm{CH}_{2}\right)$.

## Synthesis of 3-(1-(1H-indol-3-yl)cyclohexan-4-one ethylene acetal)-1H-indole 321

Indole $300(250 \mathrm{mg}, 2.13 \mathrm{mmol}, 2 \mathrm{eq})$ was added to methanol ( 3 mL ) and benzoic acid $N^{\prime}$ isopropylhyrdazide 91 ( $23 \mathrm{mg}, 0.11 \mathrm{mmol}, 0.1 \mathrm{eq}$ ) and stirred at $25^{\circ} \mathrm{C} .1,4$ cyclohexadione monoethylene ketal 319 ( $170 \mathrm{mg}, 1.07 \mathrm{mmol}$ )was added, the reaction tube, sealed and allowed to stir for 24 hrs at ambient temperature. The solvent was removed under reduced
pressure and the resulting mixture was then purified by flash column chromatography eluting with (3:1) petroleum ether/ethyl acetate to yield the title compound ( $200 \mathrm{mg}, 50 \%$ ) as an off white solid. $\mathrm{mp} 228^{\circ} \mathrm{C}$; $v_{\max }\left(\mathrm{CHCl}_{3}\right) / \mathrm{cm}^{-1} 3477,3415,3019,2932,2329,1722$, 1456,$1215 ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{H}} 7.94(2 \mathrm{H}, \mathrm{s}, \mathrm{NH}), 7.59(2 \mathrm{H}, \mathrm{d}, \mathrm{J}=8.1, \mathrm{Ar}-\underline{\mathrm{H}})$, $7.31(2 \mathrm{H}, \mathrm{d}, \mathrm{J}=8.1, \operatorname{Ar}-\underline{\mathrm{H}}), 7.10-7.06(4 \mathrm{H}, \mathrm{m}, \operatorname{Ar}-\underline{\mathrm{H}}), 6.94-6.90(2 \mathrm{H}, \mathrm{m}, \operatorname{Ar}-\underline{\mathrm{H}}), 4.00(4 \mathrm{H}, \mathrm{s}$, $\left.\mathrm{O}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{O}\right), 2.73-2.70\left(4 \mathrm{H}, \mathrm{m}, \mathrm{OCH}_{2} \mathrm{CH}_{2}\right), 1.83-1.80\left(4 \mathrm{H}, \mathrm{m}, \mathrm{OCH}_{2} \mathrm{CH}_{2}\right) ;{ }^{13} \mathrm{C}$ NMR $\left(100 \mathrm{MHz}\right.$, d6 acetone) $\delta_{\mathrm{C}} \quad 139.4(\mathrm{C}), 128.2(\mathrm{C}) 124.1(\mathrm{CH}), 122.8(\mathrm{CH}), 122.4(\mathrm{CH})$, $119.7(\mathrm{CH}), 133.1(\mathrm{CH}), 110.6(\mathrm{C}), 56.7\left(\mathrm{CH}_{2}\right), 40.3(\mathrm{C}), 35.9\left(\mathrm{CH}_{2}\right), 33.7\left(\mathrm{CH}_{2}\right)$ the other quaternary carbon was not observed. $m / z$ (APCI) (M+H); HRMS (ES) (found $[\mathrm{M}+\mathrm{H}]^{+}$ 373.1914; $\mathrm{C}_{21} \mathrm{H}_{22} \mathrm{~N}_{2} \mathrm{O}_{2}$ requires 373.1911).

Synthesis of vibrandole A 324

Indole 300 ( $500 \mathrm{mg}, 4.27 \mathrm{mmol}$, 2eq) was added to methanol ( 2.5 mL ) and benzoic acid $N^{\prime}$ isopropylhyrdazide 91 ( $46 \mathrm{mg}, 0.214 \mathrm{mmol}, 0.1 \mathrm{eq}$ ) and stirred at $25^{\circ} \mathrm{C}$. Acetylaldehyde ( 94 $\mathrm{mg}, 2.14 \mathrm{mmol}, 0.12 \mathrm{~mL}$,) was added, the reaction tube sealed and allowed to stir for 24 hrs at ambient temperature. The solvent was removed under reduced pressure and the resulting mixture was then purified by flash column chromatography eluting with $3: 1$ petroleum ether/ethyl acetate to yield the title compound $(450 \mathrm{mg}, 80 \%)$ as an off white solid. mp 155 ${ }^{\circ} \mathrm{C} ; v_{\max }\left(\mathrm{CHCl}_{3}\right) / \mathrm{cm}^{-1} 3479,3417,3018,1455,1416,1092 ;{ }^{1} \mathrm{H}$ NMR $\left(500 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}}$ $7.81(1 \mathrm{H}, \mathrm{bs}, \mathrm{NH}), 7.52(2 \mathrm{H}, \mathrm{d}, J=7.9, \mathrm{Ar}-\mathrm{H}), 7.29(2 \mathrm{H}, \mathrm{d}, J=8.1, \operatorname{Ar}-\mathrm{H}), 7.10,(2 \mathrm{H}, \mathrm{t}, J=$ 8.1, Ar-H), $6.97(2 \mathrm{H}, \mathrm{t}, J=8.0, \operatorname{Ar}-\mathrm{H}), 6.86(2 \mathrm{H}, \mathrm{d}, J=2.4, \operatorname{Ar}-\mathrm{H}), 4.61(1 \mathrm{H}, \mathrm{q}, J=7.1$, $\mathrm{CH}), 1.75\left(3 \mathrm{H}, \mathrm{d}, J=7.1, \mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C}$ NMR ( $125 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{C}} 136.7(\mathrm{C}), 126.9(\mathrm{C}) .121 .8$ $(\mathrm{CH}), 121.7(\mathrm{C}), 121.2(\mathrm{CH}), 119.8(\mathrm{CH}), 119.0(\mathrm{CH}), 111.1(\mathrm{CH}), 28.1(\mathrm{CH}), 21.8\left(\mathrm{CH}_{3}\right)$.

Synthesis of 3-(1,3-di(1 $\mathbf{H}$-indol-3-yl)butyl)-1H-indole 327

Indole $300(0.5 \mathrm{~g}, 4.27 \mathrm{mmol})$ was added to methanol ( 5 mL ) and benzoic acid $N^{\prime}$ isopropylhyrdazide 91 ( $30.5 \mathrm{mg}, 0.142 \mathrm{mmol}, 0.1 \mathrm{eq}$ ) and stirred at $25^{\circ} \mathrm{C}$. Crotonaldheyde ( $100 \mathrm{mg}, 1.42 \mathrm{mmol}, 0.12 \mathrm{~mL}$,) was added, the reaction tube sealed and allowed to stir for 24 hrs at ambient temperature. The solvent was removed under reduced pressure and the resulting mixture was then purified by flash column chromatography eluting with (3:1) petroleum ether/ethyl acetate to yield the title compound ( $290 \mathrm{mg}, 51 \%$ ) as an off white solid. The measured data is consistent with literature values ${ }^{172} \mathrm{mp} 151-154{ }^{\circ} \mathrm{C} ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{H}} 7.60-7.43(4 \mathrm{H}, \mathrm{m}, 3(\mathrm{NH}), \operatorname{Ar-H}) 7.43(1 \mathrm{H}, \mathrm{d}, \mathrm{J}=7.8, \mathrm{Ar}-\underline{\mathrm{H}}), 7.41(1 \mathrm{H}$, $\mathrm{d}, \mathrm{J}=7.8, \operatorname{Ar}-\underline{\mathrm{H}}) 7.25-7.05(6 \mathrm{H}, \mathrm{m}, \operatorname{Ar}-\underline{\mathrm{H}}), 7.04-6.90(3 \mathrm{H}, \mathrm{m}, \operatorname{Ar}-\underline{\mathrm{H}}), 6.76(1 \mathrm{H}, \mathrm{d}, \mathrm{J}=2.0$, $\operatorname{Ar}-\underline{H}), 6.70(1 \mathrm{H}, \mathrm{d}, \mathrm{J}=2.0, \mathrm{Ar}-\underline{\mathrm{H}}), 6.65(1 \mathrm{H}, \mathrm{d}, \mathrm{J}=2.0, \mathrm{Ar}-\underline{\mathrm{H}}), 4.50\left(1 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.8, \mathrm{Ar}_{2}-\mathrm{C} \underline{\mathrm{H}}\right)$, $3.00\left(1 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{3} \mathrm{CH}\right), 2.60\left(1 \mathrm{H}, \mathrm{m}, \mathrm{CHCH}_{2}\right), 2.40\left(1 \mathrm{H}, \mathrm{m}, \mathrm{CHCH}_{2}\right), 1.38(3 \mathrm{H}, \mathrm{d}, \mathrm{J}=7.0$, $\mathrm{CH}_{3} \mathrm{CH}$ ).

## Synthesis of tri(1H-indol-3-yl)methane 325

Indole $\mathbf{3 0 0}$ ( $500 \mathrm{mg}, 4.27 \mathrm{mmol}, 2 \mathrm{eq}$ ) was added to methanol ( 5 mL ) and benzoic acid $N^{\prime}$ isopropylhyrdazide 91 ( $46 \mathrm{mg}, 0.214 \mathrm{mmol}, 0.1 \mathrm{eq}$ ) and stirred at $25{ }^{\circ} \mathrm{C}$. Indole-3carboxaldehyde ( $310 \mathrm{mg}, 2.14 \mathrm{mmol}$ ) was added, the reaction tube sealed and allowed to stir for 24 hrs at ambient temperature. The solvent was removed under reduced pressure and the resulting mixture was then purified by flash column chromatography eluting with $3: 1$ petroleum ether/ethyl acetate to yield the title compound ( $590 \mathrm{mg}, 77 \%$ ) as an off white solid. ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{H}} 10.8(3 \mathrm{H}, \mathrm{d}, J=1.9, \mathrm{NH}), 7.43(3 \mathrm{H}, \mathrm{d}, J=8.0, \mathrm{Ar}-\underline{\mathrm{H}})$,
$7.39(3 \mathrm{H}, \mathrm{d}, J=8.0, \mathrm{Ar}-\underline{\mathrm{H}}), 7.07-7.05(3 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}), 6.99(3 \mathrm{H}, \mathrm{d}, J=2.0, \mathrm{Ar}-\underline{\mathrm{H}}), 6.92-6.88$ $(3 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\underline{\mathrm{H}}), 6.10\left(3 \mathrm{H}, \mathrm{s}, \mathrm{Ar}_{3} \mathrm{CH}\right){ }^{13} \mathrm{C}$ NMR ( $\left.100 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta_{\mathrm{C}} 136.7(\mathrm{C}), 127.1(\mathrm{C})$, $123.3(\mathrm{CH}), 121.7(\mathrm{CH}), 120.0(\mathrm{CH}), 119.3(\mathrm{C}), 199.0(\mathrm{CH}), 111.0(\mathrm{CH}), 31.2(\mathrm{CH})$.

## Preparation of 3,3-di(1H-indol-3-yl)indolin-2-one 326

Indole 300 ( $250 \mathrm{mg}, 2.13 \mathrm{mmol}$, 2eq) was added to methanol ( 5.0 mL ) and benzoic acid $N^{\prime}$ isopropylhyrdazide 91 ( $23.0 \mathrm{mg}, 0.107 \mathrm{mmol}, 0.1 \mathrm{eq}$ ) and stirred at $25^{\circ} \mathrm{C}$. Isatin ( 160 mg , 1.07 mmol ) was added, the reaction tube sealed and allowed to stir for 24 hrs at ambient temperature. The solvent was removed under reduced pressure and the resulting mixture was then purified by flash column chromatography eluting with $3: 1$ petroleum ether/ethyl acetate to yield the title compound ( $280 \mathrm{mg}, 72 \%$ ) as an off white solid. $\mathrm{mp} 286{ }^{\circ} \mathrm{C} ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{OD}$ ) $\delta_{\mathrm{H}} 7.32(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\mathrm{H}), 7.27-7.25(4 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\mathrm{H}), 7.05-7.03$ (3H, $\mathrm{m}, \mathrm{Ar}-\mathrm{H}), 6.99-6.96(1 \mathrm{H}, \mathrm{m}), 6.90(2 \mathrm{H}, \mathrm{s}, \mathrm{Ar}-\mathrm{H}), \quad 6.82-6.81(2 \mathrm{H}, \mathrm{m} \mathrm{Ar}-\mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR $\left(125 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{OD}\right) \delta_{\mathrm{C}} 183.4(\mathrm{C}), 143.1(\mathrm{C}), 139.6(\mathrm{C}), 137.5(\mathrm{C}), 129.8(\mathrm{CH}), 128.1(\mathrm{C})$, $127.3(\mathrm{CH}), \quad 126.4(\mathrm{CH}), \quad 124.1(\mathrm{CH}), \quad 123.2(\mathrm{CH}), \quad 122.9(\mathrm{CH}), 120.3(\mathrm{CH}), \quad 116.5(\mathrm{C})$, $113.1(\mathrm{CH})$, $\quad 111.8(\mathrm{CH}), 55.7(\mathrm{CH})$.

## Appendix

## Equation to determine rate of iminium ion formation

For a reaction where the initial concentration of $A$ and $B$ are identical

$$
\begin{equation*}
\mathrm{A}+\mathrm{B} \rightarrow \mathrm{P} \tag{1}
\end{equation*}
$$

Where A and B are the starting materials and P is the product the rate of the reaction is given by

$$
\begin{equation*}
-{ }_{d t}^{d[A]}=k \times[A][B] \tag{2}
\end{equation*}
$$

This can be rewritten as

$$
\begin{equation*}
-{ }_{d t}^{d[A]}=k \times[A]^{2} \tag{3}
\end{equation*}
$$

Through mathematical separation of the variables and integration gives

$$
\begin{equation*}
\frac{1}{[A]}=k t+C \tag{4}
\end{equation*}
$$

Provided that $[\mathrm{A}]=[\mathrm{A}]_{0}$ at $t=0$ the constant of integration becomes $1 /[\mathrm{A}]_{0}$ and therefore the integrated second order equation becomes

$$
\begin{equation*}
\frac{1}{[A]}-\frac{1}{[A]_{o}}=k t \tag{5}
\end{equation*}
$$

A plot of $1 /[\mathrm{A}] v s t$ should therefore be a straight line for a second order process and have slope $k$. The rate constants $k$ were measured using data points up to $50 \%$ conversion.

## Equation to determine the rate constant of the Diels-Alder cycloaddition

For the reaction where the initial concentration of A and B are in equivalent the variable x is introduced to give.

$$
\begin{equation*}
\frac{d x}{d t}=k\left([A]_{0}-x\right)\left([B]_{0}-x\right) \tag{6}
\end{equation*}
$$

x is the decrease in the concentration of A and B therefore $[\mathrm{A}]_{0}-x=[\mathrm{A}]$ and $[\mathrm{B}]_{0}-x=[\mathrm{B}]$. If equation is treated mathematically with separation of the variables and partial fraction expansion it can then be integrated to give

$$
\begin{equation*}
\frac{1}{[A]_{0}-[B]_{0}} \ln \frac{[A]_{0}-x}{[B]_{0}-x}=k t+C \tag{7}
\end{equation*}
$$

The constant of integration C can then be found using the condition $x=0$ when $t=0$ by equation (8)

$$
\begin{equation*}
C=\frac{1}{[A]_{0}-[B]_{0}} \ln \frac{[A]_{0}}{[B]_{0}} \tag{8}
\end{equation*}
$$

When this is substituted into equation (7) we get

$$
\begin{equation*}
\ln \frac{[A]_{0}-x}{[B]_{0}-x}=k t\left([A]_{0}-[B]_{0}\right)+\ln \frac{[A]_{0}}{[B]_{0}} \tag{9}
\end{equation*}
$$

Therefore if $[\mathrm{A}]>[\mathrm{B}]$ then a plot of $\ln \left(\left([\mathrm{A}]_{0}-\mathrm{x}\right) /\left([\mathrm{B}]_{0}-\mathrm{x}\right)\right)$ vs $t$ will have positive slope, equal to $\left([A]_{0}-[B]_{0}\right) \mathrm{k}$. The rate constant k was measured using data points up to $50 \%$ conversion.

## The Arrhenius Equation

The Arrhenius equation relates rate to activation energy is often written in the form

$$
\begin{equation*}
\ln k=-\frac{E_{a}}{R T}+\ln A \tag{10}
\end{equation*}
$$

Where k is the rate constant, $\mathrm{E}_{\mathrm{a}}$ is the activation energy, R is the gas constant, T is the temperature and A is the Arrhenius pre-exponential factor. Using this equation a plot of $\ln k$ vs $1 / \mathrm{T}$ gives a slope of $-\mathrm{E}_{\mathrm{a}} / \mathrm{R}$ with an intercept $\ln \mathrm{A}$.

## X-Ray data for iminium ion 123

Table 1. Crystal data and structure refinement.

| Identification code | 2007src0546 (TG 3.415) |
| :---: | :---: |
| Empirical formula | $\mathrm{C}_{13} \mathrm{H}_{16} \mathrm{~F}_{6} \mathrm{NP}$ |
| Formula weight | 331.24 |
| Temperature | 120(2) K |
| Wavelength | 0.71073 £ |
| Crystal system | Monoclinic |
| Space group | $P 2{ }_{1} / c$ |
| Unit cell dimensions | $a=18.0459(5) \AA \quad \alpha=90^{\circ}$ |
|  | $b=16.9680(5) \AA \quad \beta=97.198(2)^{\circ}$ |
|  | $c=9.58230(10) \AA \quad \gamma=90^{\circ}$ |
| Volume | 2911.00(12) $\AA^{3}$ |
| Z | 8 |
| Density (calculated) | $1.512 \mathrm{Mg} / \mathrm{m}^{3}$ |
| Absorption coefficient | $0.247 \mathrm{~mm}^{-1}$ |
| F(000) | 1360 |
| Crystal | Block; colourless |
| Crystal size | $0.20 \times 0.12 \times 0.04 \mathrm{~mm}^{3}$ |
| $\theta$ range for data collection | $3.31-27.50^{\circ}$ |
| Index ranges | $-23 \leq h \leq 23,-22 \leq k \leq 22,-12 \leq l \leq 11$ |
| Reflections collected | 40070 |
| Independent reflections | $6664\left[R_{\text {int }}=0.0556\right]$ |
| Completeness to $\theta=27.50^{\circ}$ | 99.5\% |
| Absorption correction | Semi-empirical from equivalents |
| Max. and min. transmission | 0.9902 and 0.9523 |
| Refinement method | Full-matrix least-squares on $F^{2}$ |
| Data / restraints / parameters | 6664 / 0 / 416 |
| Goodness-of-fit on $F^{2}$ | 1.040 |
| Final $R$ indices [ $F^{2}>2 \sigma F^{2}$ )] | $R 1=0.0552, w R 2=0.1405$ |
| $R$ indices (all data) | $R 1=0.0825, w R 2=0.1583$ |
| Largest diff. peak and hole | 0.783 and $-0.775 \mathrm{e}^{\AA^{-3}}$ |

[^2]Table 2. Atomic coordinates [ $\times 10^{4}$ ], equivalent isotropic displacement parameters [ $\AA^{2} \times 10^{3}$ ] and site occupancy factors. $U_{e q}$ is defined as one third of the trace of the orthogonalized $U^{i j}$ tensor.

## X-Ray data for iminium ion 126

Table 1. Crystal data and structure refinement.

| Identification code | 2007src1313 (TG3-446) |  |
| :---: | :---: | :---: |
| Empirical formula | $\mathrm{C}_{16} \mathrm{H}_{20} \mathrm{~F}_{9} \mathrm{~N}_{2} \mathrm{P}$ |  |
| Formula weight | 442.31 |  |
| Temperature | 120(2) K |  |
| Wavelength | 0.71073 Å |  |
| Crystal system | Monoclinic |  |
| Space group | $P 2{ }_{1} / c$ |  |
| Unit cell dimensions | $a=20.7923(9) \AA$ | $\alpha=90^{\circ}$ |
|  | $b=10.7114(5) \AA$ | $\beta=94.923(3){ }^{\circ}$ |
|  | $c=8.4013(3) \AA$ | $\gamma=90^{\circ}$ |
| Volume | 1864.19(14) $\AA^{3}$ |  |
| Z | 4 |  |
| Density (calculated) | $1.576 \mathrm{Mg} / \mathrm{m}^{3}$ |  |
| Absorption coefficient | $0.238 \mathrm{~mm}^{-1}$ |  |
| F(000) | 904 |  |
| Crystal | Blade; orange |  |
| Crystal size | $0.40 \times 0.20 \times 0.04 \mathrm{~mm}^{3}$ |  |
| $\theta$ range for data collection | 3.09-27.50 ${ }^{\circ}$ |  |
| Index ranges | $-26 \leq h \leq 26,-13 \leq k \leq 13,-10 \leq l \leq 10$ |  |
| Reflections collected | 30035 |  |
| Independent reflections | 4260 [ $R_{\text {int }}=0.0644$ ] |  |
| Completeness to $\theta=27.50^{\circ}$ | 99.7 \% |  |
| Absorption correction | Semi-empirical from equivalents |  |
| Max. and min. transmission | 0.9905 and 0.9108 |  |
| Refinement method | Full-matrix least-squares on $F^{2}$ |  |
| Data / restraints / parameters | 4260 / 0 / 255 |  |
| Goodness-of-fit on $F^{2}$ | 1.025 |  |
| Final $R$ indices [ $F^{2}>2 \sigma F^{2}$ )] | $R 1=0.0520, w R 2=0.1308$ |  |
| $R$ indices (all data) | $R 1=0.0690, w R 2=0.1421$ |  |
| Largest diff. peak and hole | 0.530 and $-0.493 \mathrm{e}^{\text {A }}{ }^{-3}$ |  |

[^3]
## Special details:

Table 2. Atomic coordinates [ $\times 10^{4}$ ], equivalent isotropic displacement parameters $\left[\AA^{2} \times 10^{3}\right]$ and site occupancy factors. $U_{e q}$ is defined as one third of the trace of the orthogonalized $U^{i j}$ tensor.

| Atom | $x$ | $y$ | $z$ | $U_{e q}$ | S.o.f. |

## X-ray structure for compound 257

Table 1. Crystal data and structure refinement.

| Identification code | 2006src0812 / TG218 |
| :---: | :---: |
| Empirical formula | $\mathrm{C}_{13} \mathrm{H}_{16} \mathrm{~N}_{2} \mathrm{O}_{4}$ |
| Formula weight | 264.28 |
| Temperature | 120(2) K |
| Wavelength | 0.71073 Å |
| Crystal system | Orthorhombic |
| Space group | $P 2_{1} 2_{1} 2_{1}$ |
| Unit cell dimensions | $a=8.1869(3) \AA \quad \alpha=90^{\circ}$ |
|  | $b=10.1197(3) \AA \quad \beta=90^{\circ}$ |
|  | $c=15.8896(4) \AA \quad \gamma=90^{\circ}$ |
| Volume | 1316.44(7) $\AA^{3}$ |
| Z | 4 |
| Density (calculated) | $1.333 \mathrm{Mg} / \mathrm{m}^{3}$ |
| Absorption coefficient | $0.100 \mathrm{~mm}^{-1}$ |
| $F(000)$ | 560 |
| Crystal | Slab; Colourless |
| Crystal size | $0.62 \times 0.36 \times 0.09 \mathrm{~mm}^{3}$ |
| $\theta$ range for data collection | $3.26-27.48^{\circ}$ |
| Index ranges | $-10 \leq h \leq 10,-13 \leq k \leq 13,-20 \leq l \leq 20$ |
| Reflections collected | 13552 |
| Independent reflections | 1744 [ $\left.R_{\text {int }}=0.0402\right]$ |
| Completeness to $\theta=27.48^{\circ}$ | 99.7 \% |
| Absorption correction | Semi-empirical from equivalents |
| Max. and min. transmission | 0.9911 and 0.9407 |
| Refinement method | Full-matrix least-squares on $F^{2}$ |
| Data / restraints / parameters | 1744/0/175 |
| Goodness-of-fit on $F^{2}$ | 1.045 |
| Final $R$ indices [ $\left.F^{2}>2 \sigma F^{2}\right)$ ] | $R 1=0.0323, w R 2=0.0770$ |
| $R$ indices (all data) | $R 1=0.0437, w R 2=0.0823$ |
| Absolute structure parameter | ? |
| Extinction coefficient | 0.016(3) |
| Largest diff. peak and hole | 0.183 and $-0.156 \mathrm{e}^{\AA^{-3}}$ |

Diffractometer: Nonius KappaCCD area detector ( $\phi$ scans and $\omega$ scans to fill asymmetric unit sphere). Cell determination: DirAx (Duisenberg, A.J.M.(1992). J. Appl. Cryst. 25, 92-96.) Data collection: Collect (Collect: Data collection software, R. Hooft, Nonius B.V., 1998). Data reduction and cell refinement: Denzo ( Z . Otwinowski \& W. Minor, Methods in Enzymology (1997) Vol. 276: Macromolecular Crystallography, part A, pp. 307-326; C. W. Carter, Jr. \& R. M. Sweet, Eds., Academic Press). Absorption correction: SADABS Version 2.10. (G. M. Sheldrick (2003)) Bruker AXS Inc., Madison, Wisconsin, USA. Structure solution: SHELXS97 (G. M.

Sheldrick, Acta Cryst. (1990) A46 467-473). Structure refinement: SHELXL97 (G. M. Sheldrick (1997), University of Göttingen, Germany). Graphics: ORTEP3 for Windows (L. J. Farrugia, J. Appl. Crystallogr. 1997, 30, 565).

## Special details:

All hydrogen atoms were fixed.
It was not possible to accurately determine the absolute structure. The stereochemistry picked was based on the precursor molecule.

Table 2. Atomic coordinates [ $\times 10^{4}$ ], equivalent isotropic displacement parameters $\left[\AA^{2} \times 10^{3}\right.$ ] and site occupancy factors. $U_{e q}$ is defined as one third of the trace of the orthogonalized $U^{i j}$ tensor.

Symmetry transformations used to generate equivalent atoms:
(i) $x-1, y, z$

## X-Ray structure of compound 259

Table 1. Crystal data and structure refinement.

| Identification code | 2006src0919 (TG305) |
| :---: | :---: |
| Empirical formula | $\mathrm{C}_{11} \mathrm{H}_{13} \mathrm{NO}_{3}$ |
| Formula weight | 207.22 |
| Temperature | 120(2) K |
| Wavelength | 0.71073 £ |
| Crystal system | Orthorhombic |
| Space group | $P 21_{1} 2_{1} 2_{1}$ |
| Unit cell dimensions | $a=8.2328(2) \AA \quad \alpha=90^{\circ}$ |
|  | $b=11.1850(2) \AA \quad \beta=90^{\circ}$ |
|  | $c=11.3300(2) \AA \quad \gamma=90^{\circ}$ |
| Volume | 1043.31(4) $\AA^{3}$ |
| Z | 4 |
| Density (calculated) | $1.319 \mathrm{Mg} / \mathrm{m}^{3}$ |
| Absorption coefficient | $0.097 \mathrm{~mm}^{-1}$ |
| $F(000)$ | 440 |
| Crystal | Slab; colourless |
| Crystal size | $0.60 \times 0.40 \times 0.12 \mathrm{~mm}^{3}$ |
| $\theta$ range for data collection | $3.56-27.47^{\circ}$ |
| Index ranges | $-10 \leq h \leq 10,-14 \leq k \leq 14,-14 \leq l \leq 14$ |
| Reflections collected | 14281 |
| Independent reflections | 2380 [ $\left.R_{\text {int }}=0.0312\right]$ |
| Completeness to $\theta=27.47^{\circ}$ | 99.2\% |
| Absorption correction | Semi-empirical from equivalents |
| Max. and min. transmission | 0.9885 and 0.9444 |
| Refinement method | Full-matrix least-squares on $F^{2}$ |
| Data / restraints / parameters | 2380/0/141 |
| Goodness-of-fit on $F^{2}$ | 1.044 |
| Final $R$ indices [ $F^{2}>2 \sigma\left(F^{2}\right)$ ] | $R 1=0.0317, w R 2=0.0779$ |
| $R$ indices (all data) | $R 1=0.0384, w R 2=0.0814$ |
| Absolute structure parameter | 0.0(9) |
| Largest diff. peak and hole | 0.119 and $-0.211 \mathrm{e}^{-3}$ |

[^5]correction: SORTAV (R. H. Blessing, Acta Cryst. A51 (1995) 33-37; R. H. Blessing, J. Appl. Cryst. 30 (1997) 421-426). Structure solution: SHELXS97 (G. M. Sheldrick, Acta Cryst. (1990) A46 467-473). Structure refinement: SHELXL97 (G. M. Sheldrick (1997), University of Göttingen, Germany). Graphics: Cameron - A Molecular Graphics Package. (D. M. Watkin, L. Pearce and C. K. Prout, Chemical Crystallography Laboratory, University of Oxford, 1993).

Table 2. Atomic coordinates $\left[\times 10^{4}\right]$, equivalent isotropic displacement parameters $\left[\AA^{2} \times 10^{3}\right]$ and site occupancy factors. $U_{e q}$ is defined as one third of the trace of the orthogonalized $U^{i j}$ tensor.
