## Summary

The configurational stability of a range of stereogenic centres in aqueous media has been studied, with the goal of understanding the structural and environmental factors contributing to configurational instability. This information will be of use to the pharmaceutical industry, for which the chiral integrity of drug compounds is imperative. Chapter 1 outlines the background to this project, providing an overview of pharmacological racemisation including potential mechanisms, examples from literature, and the methodology used.

Chapter 2 focuses on database mining studies undertaken on AstraZeneca compound libraries, the results of which guided the structures investigated in the rest of the thesis. Most compounds in the libraries do not appear at risk of racemisation. Of those that do, stereogenic centres with proton, carbonyl, aromatic and nitrogen substituents appear most frequently.

Chapter 3 discusses experimental work determining rate constants of proton-deuterium exchange (as a model for racemisation) under physiological conditions, for a set of $N$-acetyl arylglycine methyl esters. These rate constants suggest that such compounds are susceptible to in vivo racemisation through an $\mathrm{S}_{\mathrm{E}} 1$ mechanism.

Chapter 4 outlines experimental work determining rate constants of proton-deuterium exchange, for a set of $N$-substituted phenylglycine amides. These compounds undergo H/D exchange through an $S_{E} 1$ mechanism, although the rate at which $H / D$ exchange occurs suggests they would not be at risk of in vivo racemisation. These results show that an amide substituent is far weaker than a methyl ester in facilitating racemisation.

Chapter 5 reports the results of computational studies performed on the compounds investigated in Chapters 3 and 4. The energy gap between a molecule and its anion when deprotonated at the stereogenic centre was correlated with the experimentally determined data, suggesting that prediction of configurational instability for novel compounds may be possible. This correlation only holds when the PCM solvent model is used in calculations.

## Acknowledgements

First and foremost, I would like to thank my supervisor, Dr Niek Buurma, for giving me the opportunity to undertake this project. Without his guidance, advice and enthusiasm, completion of this thesis would not have been possible. My industrial supervisor at AstraZeneca, Dr Andrew Leach, has also been a massive help. His assistance, particularly with the database mining studies, and his willingness to travel down from Cheshire on a regular basis for meetings is greatly appreciated. Thanks must also go to AstraZeneca and the EPSRC for providing funds for this project.

At Cardiff, I particularly want to thank Dr Rob Richardson for many useful discussions and helping me with the computational work. Thanks to Prof Barry Carpenter and Dr Eric Tippmann for being my internal examiners over the years and providing assistance throughout the project. Dr Larry Goldman also deserves a special mention for his help with computational work, as does Stefania Narduolo for working alongside me on a similar project and being very cooperative with sharing data and knowledge, and Dr Ian Morgan who was a big help especially in the early days of the project. Fellow Buurma group members Mihaela, Mazin, Ismail, Azzedine, and Lavinia and POC members Julia, Ed, Jamie, Alicja and Zuska are also thanked. Dr Rob Jenkins deserves my gratitude for his patience with me using the NMR spectrometers far more than my fair share. Thanks also to Robin and Dave for keeping the instruments running and returning mass spectra quickly, and to Gaz, Jamie and Mal in stores.

At AstraZeneca, I am grateful to Dr Nabil Asaad for devising the project alongside Niek and helping it get off the ground. Dr Simone Tomasi is also thanked for his involvement and ideas throughout the project. For two periods whilst working in this project I was based at AZ's Alderley Park facility, and several people need to be thanked for making my time there both enjoyable and fruitful. A big, big thank you goes to Chris and Saj Jones, and then Rich and Clare Ward, for their generosity in hosting me during these periods and making me feel welcome. The LCMS work in Chapter 4 was conducted during this period and I am very grateful to Dr Matt Wood and all members of the Physical Chemistry team at Alderley Park for allowing me into their lab and giving up time to help me complete this work within a tight time schedule.

Outside of the project itself there are many people who have helped me get to this point. I would like to thank all my friends for helping keep me sane whilst I've been working on this
project. Being able to play football to a good standard and with great friends has been especially important, and so thanks to all the lads from AC Central, AFC Egham, Dynamo Centurion and Team Colon. Many thanks go to my family, particularly mum and dad, for all their love and support throughout this period. Most importantly, I'd like to thank Lucy for being there for me throughout.

## Table of Contents

1 INTRODUCTION ..... 1
1.1 Project Background .....  1
1.2 Definitions ..... 3
1.3 Mechanism .....  4
1.4 Substituent Effects .....  8
1.5 Racemisation Case Studies ..... 13
1.5.1 Base-Catalysed Racemisation of Stereocentres of the Type R''R'RC-H ..... 19
1.5.2 Other Mechanisms of Racemisation ..... 22
1.6 Acid and Base Catalysis ..... 26
1.6.1 Acid Catalysis ..... 26
1.6.2 Base Catalysis ..... 27
1.7 Kinetic Isotope Effects ..... 28
1.8 Linear Free-Energy Relationships ..... 30
1.8.1 The Bronsted Catalysis Law ..... 30
1.8.2 The Hammett Equation ..... 33
1.8.2.1 Factors Affecting $\rho$ ..... 36
1.8.2.1.1 Distance Between Reaction Site and Aromatic Substituent ..... 36
1.8.2.1.2 Temperature Dependence of $\rho$ ..... 37
1.8.2.1.3 Non-linearity ..... 37
1.8.2.2 Modifications of the Hammett Equation ..... 38

## 1 Introduction

### 1.1 Project Background

Chirality is of major interest in the research and development of novel pharmacologically active molecules. In 2008, it was estimated that around $50 \%$ of marketed drugs are chiral, ${ }^{1}$ increased from $40 \%$ in $1993 .{ }^{2}$ In the past 30 years there has also been a drastic increase in the proportion of drugs solely administered as a single-enantiomer. In 2003 not a single new drug on the market was administered as a racemate, ${ }^{3}$ and the three top-selling drugs of $2008^{*}$ were all single-enantiomers. ${ }^{4}$ Alongside this move away from developing new drugs as racemates is the strategy of many pharmaceutical companies known as a 'chiral switch', whereby drugs previous marketed as a racemate are re-marketed as a single-enantiomer. ${ }^{5-7}$ The switch to homochirality can be therapeutically advantageous and can therefore enable the manufacturer to extend the duration of patent protection. It has also been shown that the presence of a chiral carbon within a molecule correlates with its successful transition from discovery to marketable drug. ${ }^{8}$

Because of the chiral environment found within the human body, opposing enantiomers for many chiral molecules can have drastically different physiological actions. ${ }^{9,10}$ Enantiomers of some compounds stimulate different smell and taste receptors to produce different odours and flavours. ${ }^{11,12}$ Of greater interest are the different pharmaceutical properties found in many drug molecules. Most pharmaceuticals dispensed as a racemate have one enantiomer ('eutomer') that is more bioactive than the other ('distomer'). ${ }^{13}$ For the class of compounds known as non-steroidal anti-inflammatory agents only one enantiomer is pharmaceutically active. An example of this is ibuprofen, shown in Scheme 1.1. ${ }^{14}$

(+)-(S)-Ibuprofen
anti-inflammatory

$(-)-(R)$-Ibuprofen inactive

Scheme 1.1: Enantiomers of ibuprofen.

[^0]The administration as a racemate of drugs such as ibuprofen results in a reduction of the effective dose. The therapeutically non-active isomer of the drug can essentially be considered an impurity. ${ }^{15}$ More significantly, in some cases the enantiomer of a pharmacologically active drug may be harmful to the patient. The molecule thalidomide (Scheme 1.2) is often cited as an example.

$(+)-(R)$-Thalidomide sedative

(-)-(S)-Thalidomide teratogen

Scheme 1.2: Enantiomers of thalidomide.
Thalidomide was administered to pregnant women in the late 1950's to ease morning sickness pains. It was later discovered to be teratogenic, resulting in many recipients of the drug giving birth to babies with severe deformities. It has since been documented that the teratogenic activity is caused by the ( $S$ )-enantiomer only. ${ }^{16-18}$ Other studies have suggested that both enantiomers can cause birth defects. ${ }^{19,20}$ Either way, one legacy of this tragedy was to increase awareness of the potential hazards of the presence of more than one enantiomer in a drug. It has been contended that administration of enantiopure $(R)$-thalidomide would have prevented the catastrophe. ${ }^{21,22}$ However, this would not solve the problem as thalidomide racemises under physiological conditions. In vivo experiments showed half-lives of chiral inversion of less than 6 hours in humans. ${ }^{23,}{ }^{24}$ As a result, the administration of only one enantiomer of thalidomide as a drug will not prevent the presence of both enantiomers within the body.

To minimise the possibility of an incident such as that involving thalidomide occurring again, confirmation that a potential drug molecule is configurationally stable under certain conditions must be obtained prior to its release. ${ }^{25}$ The configurational stability at ambient temperature and humidity over a period of many months should be determined to ensure the shelf life of the drug is known. Of greater risk is that a drug may undergo racemisation in the blood stream, as in the case of thalidomide. Therefore the configurational stability of the molecule of interest should be known under aqueous conditions, at temperatures $\sim 37^{\circ} \mathrm{C}$ and at pH levels from neutral down to very acidic.

The susceptibility of a compound to racemise is evidently related to its molecular structure. The mechanism by which a molecule undergoes racemisation is largely dependent on the interaction between molecular structure and its environment. It is therefore of interest to the pharmaceutical industry and chemists in general to understand this interaction, to allow insight into which aspects of the molecular structure facilitate racemisation under physiological conditions.

Knowledge of the structural factors affecting racemisation could also be of use in areas other than the configurational stability of drugs. In dynamic kinetic resolutions (DKRs) for example, racemisation is harnessed in the production of enantiomerically pure compounds. ${ }^{26-}$ ${ }^{28}$ Kinetic resolution of a racemic material works on the basis that the two enantiomers are transformed to products at different rates (e.g. in an enzymatic transformation), with the desired enantiomer reacting faster. In a DKR, the start material is simultaneously racemised. This allows the transformation of all the racemic start material to the desired enantiopure product. Racemisation must occur faster than reaction of the undesired starting enantiomer in order for the DKR to be effective. As a result, understanding of the structural factors that facilitate or hinder racemisation could also be informative to chemists working on DKR procedures.

### 1.2 Definitions

It is important to define the concepts of racemisation and enantiomerisation. ${ }^{29,}{ }^{30}$ Racemisation (Scheme 1.3) is a statistical, macroscopic and irreversible process in which half of an enantiopure quantity of compound is transformed into the opposing enantiomer. It is complete when the enantiomeric excess (ee) of the sample under analysis is reduced to $0 \%$. Accordingly, the half-life of racemisation is the length of time it takes for the ee of a sample to drop to half its original value. Distinct from this is enantiomerisation (Scheme 1.4), which refers to the microscopic, reversible conversion of one molecule of an enantiomer into the other.
(R) (R)

| $(S)$ |  |
| :---: | :---: |
| $(R)$ | $(S)$ |
| $(R)$ |  |
| $(R)$ |  |$\stackrel{k_{\mathrm{rac}}}{\rightleftarrows}$

(S)

Scheme 1.3: Illustration of racemisation.

$$
(R) \xlongequal[k_{\text {enant }}]{k_{\text {enant }}}(S)
$$

Scheme 1.4: Illustration of enantiomerisation.
Chiral inversion of one molecule to its enantiomer reduces the $e e$ by two molecules. The rate constant of racemisation $\left(k_{\mathrm{rac}}\right)$ is therefore twice that of enantiomerisation ( $k_{\text {enan }}$ ) (eqn 1.1).

$$
\begin{equation*}
k_{\mathrm{rac}}=2 k_{\text {enan }} \tag{1.1}
\end{equation*}
$$

The rate of diastereoisomerisation (Scheme 1.5) is more complex than the rates of racemisation or enantiomerisation.

Scheme 1.5: Illustration of diastereoisomerisation.
As diastereoisomers have (by definition) inequivalent thermodynamic stabilities, the rate constant of conversion of one diastereomer into another will differ from that of the reverse reaction (eqn 1.2).

$$
\begin{equation*}
k_{1} \neq k_{-1} \tag{1.2}
\end{equation*}
$$

The definition of epimers as 'diastereoisomers that differ in only one configuration of two or more elements of chirality ${ }^{29}$ means that the example displayed in Scheme 1.5 could also be referred to as epimerisation.

### 1.3 Mechanism

Although one can never be $100 \%$ certain of the mechanism by which organic molecules react, ${ }^{31}$ information on the path a particular reaction (or series of reactions) take affords insight into the factors affecting the mechanism. In the context of this thesis, for example, awareness of the mechanism by which a racemisation reaction takes place could allow prediction of stereocentres that may be susceptible, or conditions under which certain stereocentres are at risk. For stereocentres of the type $\mathrm{R}^{\prime}{ }^{\prime}{ }^{\prime} \mathrm{RC}-\mathrm{H},{ }^{\dagger}$ the rate constant of

[^1]exchange between the proton bound to the stereogenic centre with deuterium (or tritium) from the environment in which the reaction is being studied, can be compared with the rate constant of racemisation to provide insight into the mechanism of racemisation. There are four limiting ratios of $k_{\text {deut }}$ (rate constant of deuteration) divided by $k_{\text {rac }}$ (rate constant of racemisation): ${ }^{32,33}$

1) if H/D exchange occurs with retention of stereochemistry, the ratio $k_{\text {deut }} / k_{\text {rac }}$ tends to infinite (isoinversion)
2) if $H / D$ exchange occurs with total racemisation, deuteration can occur on either face and the ratio $k_{\text {deut }} / k_{\text {rac }}$ is equal to 1
3) if H/D exchange occurs with complete stereochemical inversion, then for each event the $e e$ is reduced by two molecules and the ratio $k_{\text {deut }} / k_{\text {rac }}$ is equal to 0.5
4) if racemisation occurs with no $\mathrm{H} / \mathrm{D}$ exchange, the ratio $k_{\text {deut }} / k_{\text {rac }}$ tends to 0 .

H/D exchange with retention of stereochemistry has been observed in a handful of examples. ${ }^{34-36}$ Dehydronation at the stereogenic centre by a base such as ammonia ( $k_{1}$ ) can be followed by rehydronation on the same face by the same base molecule ( $k_{-1}$ '), if rotation of the base ion $\left(k_{2}\right)$ is faster than ion pair dissociation $\left(k_{3}\right)$ (Scheme 1.6).

$$
\mathrm{R}=\mathrm{CON}\left(\mathrm{CH}_{3}\right)_{2}
$$

Racemic Product
Dissociated ions
Retained Configuration

Scheme 1.6: Mechanism of H/D exchange with retention of configuration. ${ }^{32}$

The rate constants depicted in Scheme 1.6 are temperature and solvent dependent. The retention mechanism applies when $k_{2}$ and $k_{-1}$ are greater than $k_{3}$. When this is the case, $k_{\text {deut }} /$ $k_{\mathrm{rac}}>1$. At $145^{\circ} \mathrm{C}$ in tetrahydrofuran with 0.3 M ammonia, $k_{\mathrm{deut}} / k_{\mathrm{rac}}=148$ for the reaction depicted in Scheme 1.6.

An $S_{E} 1$ mechanism will result in equal rates of $H / D$ exchange and racemisation. The $S_{E} 1$ mechanism entails the initial rate-determining loss of a proton to give a planar carbanion, which can then be deuterated on either face (Scheme 1.7).

Scheme 1.7: $\mathrm{S}_{\mathrm{E}} 1$ mechanism of racemisation.
If a negative charge can be delocalised onto adjacent functional groups, the carbanion intermediate will be stabilised (see Section 1.4). Equal rates of proton deuterium exchange and racemisation have been observed in several circumstances where a negative charge can be stabilised through delocalisation. ${ }^{37-40}$

If $\mathrm{H} / \mathrm{D}$ exchange occurs with stereochemical inversion, $k_{\text {deut }} / k_{\mathrm{rac}}$ is equal to 0.5 and the $\mathrm{S}_{\mathrm{E}} 2$ 'push-pull' mechanism is presumed to be occurring. The $\mathrm{S}_{\mathrm{E}} 2$ mechanism consists of simultaneous bond cleavage and bond formation with a hydron as both the incoming and leaving group, resulting in chiral inversion (Scheme 1.8).

Scheme 1.8: $\mathrm{S}_{\mathrm{E}} 2$ mechanism of racemisation.
Reist et al. proposed an $\mathrm{S}_{\mathrm{E}} 2$ mechanism for the racemisation of 5-substituted hydantoins, based on an observed $k_{\text {deut }} / k_{\text {rac }}$ ratio of 0.5. ${ }^{33}$

Adjacent groups that can stabilise a negative charge, and thus facilitate racemisation through the $\mathrm{S}_{\mathrm{E}} 1$ mechanism, may also promote racemisation through an $\mathrm{S}_{\mathrm{E}}$ 2-like mechanism, although bond breaking and bond formation may not occur precisely simultaneously. If the bond with
the leaving proton is broken before the new bond with the incoming deuteron is formed, but there is insufficient time for the ion-pair intermediate to fully dissociate before the new bond is formed, then chiral inversion will still be seen and $k_{\text {deut }}=1 / 2 k_{\mathrm{rac}}=k_{\text {enan }}$. Negative charge will be built up though, and this can be stabilised by adjacent functional groups.

The continuum of mechanisms by which an electrophilic substitution of a proton by a deuteron takes place can be summarised by a More O'Ferrall-Jencks diagram (Scheme 1.9). ${ }^{41}$ The $x$ - and $y$-axes of the diagram correspond to the extent of C -D bond formation and the C - H bond being broken, respectively. Starting material is typically represented by the bottom-left-hand corner of the diagram and the product of the electrophilic substitution in the top-right-hand corner. The $\mathrm{S}_{\mathrm{E}} 1$ mechanism goes via the top left hand corner, with the $\mathrm{C}-\mathrm{H}$ bond being broken before the C-D bond is formed. The $\mathrm{S}_{\mathrm{E}} 2$ mechanism, with simultaneous C-H bond breaking and C-D bond formation, is depicted by a diagonal line proceeding from the origin to the top right corner. An $\mathrm{S}_{\mathrm{E}} 2$-like mechanism, with negative charge build up, but not enough time for the ion-pair intermediate to break apart, will proceed somewhere inbetween the 'pure' $\mathrm{S}_{\mathrm{E}} 1$ and $\mathrm{S}_{\mathrm{E}} 2$ mechanisms.

Scheme 1.9: More O'Ferrall-Jencks diagram for electrophilic substitution reactions.

Addition of the deuteron followed by loss of a proton (as depicted in the bottom-right-hand corner of Scheme 1.9) is unlikely for carbon-based chiral centres as it would involve the formation of a pentavalent carbocation intermediate.

There are many other routes through which drug-like molecules may undergo racemisation. These will be explored further in Section 1.5.2.

### 1.4 Substituent Effects

As discussed above, certain functional groups can stabilise a negative charge and as such can facilitate racemisation of stereogenic centres of the type R''R'RC-H. Similarly, there are certain functional groups that destabilise a negative charge and hence promote configurational stability. Testa et al. classified several functional groups as either increasing, decreasing or neutral to configurational stability (Table 1.1) and concluded that in order to be of pharmaceutical or pharmacological significance, there must be either three carbanion-stabilising groups present or two carbanion-stabilising groups (one of which must be strongly so) and one neutral group. ${ }^{42,43}$

Table 1.1: List of functional groups affecting the configurational stability of stereogenic centres of the type R' R ' RC - H (reproduced from reference 42).

| Groups decreasing configurational stability (acid-strengthening) | Neutral groups | Groups increasing configurational stability (acid-weakening) |
| :---: | :---: | :---: |
| -CO-O-R (strong) | $-\mathrm{CH}_{3}$ | $-\mathrm{COO}^{-}$ |
| -CO-aryl (strong) | $-\mathrm{CH}_{2} \mathrm{CH}_{3}$ | $-\mathrm{SO}_{3}{ }^{-}$ |
| -CONRR' |  |  |
| -OH |  |  |
| -Halogens |  |  |
| -Pseudohalogens |  |  |
| -NRR' |  |  |
| $-\mathrm{N}=\mathrm{R}$ |  |  |
| -Aryl |  |  |
| - $\mathrm{CH}_{2}$-aryl |  |  |
| - $\mathrm{CH}_{2} \mathrm{OH}$ |  |  |

The classifications in Table 1.1 as decreasing or increasing configurational stability can be seen as a direct consequence of the ability of the functional groups to stabilise or destabilise a negative charge, either through direct resonance delocalisation or inductive contributions. Groups such as a carbonyl, nitrile or aryl will be able to stabilise a carbanion through delocalisation (Scheme 1.10).

Scheme 1.10: Stabilisation of an anion by carbonyl, nitrile and aryl groups.
Table 1.1 also suggests that adjacent amide (orientated with nitrogen adjacent to the stereogenic centre) and amine groups will stabilise a negative charge and decrease configurational stability. In these two cases, direct delocalisation of charge cannot be depicted as in Scheme 1.10, although work by the Richard group supports the supposition that these groups, amengst others, stabilise a negative charge. ${ }^{44,45}$

The Richard group has published substantial information on the stability of carbanions in water. ${ }^{44-53}$ By determining equilibrium constants for formation of carbanions (i.e. $\mathrm{p} K_{\mathrm{a}}$ 's of carbon acids), structural effects on the stability of the carbanion can be quantified through the variation of these equilibrium constants. $\mathrm{p} K_{\mathrm{a}}$ 's were obtained from the ratio of the rate constants for the reversible proton transfer from the carbon acid to either the solvent or to a Brønsted base, together with the $\mathrm{p} K_{\mathrm{a}}$ of the reacting base. ${ }^{44}$ One method used for determination of these rate constants of deprotonation for carbon acids was through monitoring deuterium incorporation into the compound using $\mathrm{D}_{2} \mathrm{O}$ as a solvent. Rate constants for protonation of the carbanion were estimated by using an encounter-controlled reaction as a 'clock' for proton-transfer. For reactions of carbanions, which exist in water only
for as long as solvent reorganisation can occur, the rate constant for the dielectric relaxation (reorganisation) of solvent water ( $k_{\text {reorg }} \approx 10^{11} \mathrm{~s}^{-1}$ ) can be used as such a 'clock'. ${ }^{46,48}$

Richard et al. ${ }^{44,49}$ found that the addition of an adjacent $-\mathrm{NH}(\mathrm{Ac})$ group made a proton more acidic by more than $4 \mathrm{p} K_{\mathrm{a}}$ units (Scheme 1.11a). The authors attribute this to extra stabilisation of the intermediate carbanion by electrostatic interactions with a partial positive charge on the amide nitrogen (Scheme 1.11b).
a)

$$
\mathrm{p} K_{\mathrm{a}}=18.7
$$

$$
\mathrm{p} K_{\mathrm{a}}=14.5
$$

Scheme 1.11 a) Illustration of $\mathrm{p} K_{\mathrm{a}}$ change upon addition of an acetyl amide group b) stabilising electrostatic interactions between an enolate anion and the partial positive charge on amide nitrogen. ${ }^{44}$

A protonated amine adjacent to a carbon acid will stabilise the conjugate base carbanion because of its positive charge (Scheme 1.12).

Scheme 1.12: Stabilisation of anion by protonated amine.
Rios and Richard ${ }^{45}$ found that the rate constant for deuterium incorporation at $\alpha$-carbon in $\mathrm{D}_{2} \mathrm{O}$ was 3500 times greater for N -protonated glycine methyl ester than for ethyl acetate. The greater rate constant was attributed to the effect of the $\mathrm{NH}_{3}{ }^{+}$group on enolate stability, resulting in a lower $\mathrm{p} K_{\mathrm{a}}$. The importance of this positive charge on the amine is further clear from the decrease in $\mathrm{p} K_{\mathrm{a}}$ values for the proton at the $\alpha$-carbon for the glycine anion upon protonation. The positive charge on the amine makes the proton at the $\alpha$-carbon more acidic by 5 orders of magnitude (Scheme 1.13).44,50

$\mathrm{p} K_{\mathrm{a}}=34$

$\mathrm{p} K_{\mathrm{a}}=29$

Scheme 1.13: Change in $\mathrm{p} K_{\mathrm{a}}$ value upon protonation of adjacent amine. ${ }^{44}$
The classification in Table 1.1 of an imine as decreasing configurational stability is also supported by work of the Richard group. Addition of acetone to N -protonated glycine methyl ester to form the iminium adduct was shown to lower the $\mathrm{p} K_{\mathrm{a}}$ of the adjacent proton by 7 (Scheme 1.14). ${ }^{51}$

$$
\mathrm{p} K_{\mathrm{a}}=21
$$

$$
\mathrm{p} K_{\mathrm{a}}=14
$$

Scheme 1.14: Change in $\mathrm{p} K_{\mathrm{a}}$ upon formation of an iminium ion from a protonated amine.

Richard et al. ${ }^{49,52}$ also summarised the effect of different carbonyl groups on carbon acidity (Table 1.2).

Table 1.2: Effect of carbonyl substituents on $\mathrm{p} K_{\mathrm{a}}$ of $\alpha$-carbon.

|  | X | p $K_{\text {a }}$ |
| :---: | :---: | :---: |
| 0 | H | 16.7 |
|  | Me | 19.3 |
|  | SEt | 21.0 |
|  | OMe | 25.6 |
|  | OH | 26.6 |
| $+\mathrm{H}^{\oplus}$ | $\mathrm{NH}_{2}$ | 28.4 |
| X | $\mathrm{O}^{-}$ | 33.5 |
|  | $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{CH}_{3}$ | 18.7 |

The authors suggest two factors for the range of $\mathrm{p} K_{\mathrm{a}}$ values seen in Table 1.2;1) the polar effect of electron-withdrawing groups that stabilise negative charge at the enolate ion, and 2) the $\pi$-donor effect of interactions between any substituent lone-pair and the electron deficient $\pi$-orbital of the adjacent carbonyl carbon.

The $\mathrm{p} K_{\mathrm{a}}$ values reported in Table 1.2 suggest that a methyl ester group is more carbanion stabilising than a primary amide group, by two orders of magnitude. This difference was attributed to the partial carbon-nitrogen double-bond character of amides, due to resonance delocalisation of the nitrogen lone pair onto the carbonyl oxygen. The presence of a negative charge on the carbonyl oxygen of a primary amide prevents delocalisation of any negative charge built up during enolisation.

In Table 1.1, Testa et al. defined both aryl ketone and ester groups as strongly configurationally destabilising. As shown in Table 1.2, Richard et al. ${ }^{49,52}$ found that the $\alpha$ carbon of an aryl ketone has a far lower $\mathrm{p} K_{\mathrm{a}}\left(7 \mathrm{p} K_{\mathrm{a}}\right.$ units) than that of a methyl ester. This lower $\mathrm{p} K_{\mathrm{a}}$ suggests that an aryl ketone substituent would be far more configurationally destabilising than a methyl ester substituent, if positioned adjacent to a stereogenic centre.

Although possessing a carbonyl, a carboxylate anion is said to increase configurational stability. This is because an adjacent anion will destabilise any negative charge built up during racemisation (Scheme 1.15).

unfavourable
Scheme 1.15: Destabilisation of an anion by carboxylate group.
The $\mathrm{p} K_{\mathrm{a}}$ of a carboxylic acid is obviously dependent on the structure of the rest of the molecule but is generally $<5 .{ }^{54}$ Therefore we can assume that under physiological conditions the carboxylate will be deprotonated and hence an anion will be present. This effect on carbanion stability is also reflected in Table 1.2 , where the $\mathrm{p} K_{\mathrm{a}}$ of the carboxylate anion substituted ketone is 8 units lower than the equivalent methyl ester compound.

In conclusion, existing studies generally support the assignments in Table 1.1, although many of the listed functional groups appear untested. It is also important to acknowledge that configurational stability is a relative term and that nearly all stereogenic centres can be
destabilised under certain conditions. ${ }^{43}$ The assignments in Table 1.1 are made with regards to physiological conditions as set out in Section 1.1. Functional group dependence will be further discussed in the following section containing case studies of racemisation.

### 1.5 Racemisation Case Studies

There are many examples of in vitro studies on the racemisation of drugs or drug-like molecules. A review article on the subject was written by Ali et al. ${ }^{55}$ and a review on racemisation in general by Ebbers et al. ${ }^{56}$ Rate constants, conditions and mechanisms of racemisation of some chiral compounds (including several drugs) are listed in Table 1.3.

As noted, the rate constants in Table 1.3 were obtained under a variety of conditions. This means that direct comparisons between the compounds in Table 1.3 will be of little value, although approximate qualitative evaluations can be made.

### 1.5.1 Base-Catalysed Racemisation of Stereocentres of the Type R"R'RC-H

Many of the entries in Table 1.3 are for racemisation of stereocentres of type R''R'RC-H, catalysed by base. Although a specific mechanism was not concluded for some of these entries, a rate-determining step involving proton abstraction by specific or general base is plausible in all. As such, the data can be used as a basis for comparison of the role adjacent functional groups play in facilitating racemisation of $\mathrm{R}^{\prime \prime}$ ' RC - H type stereocentres, seemingly through stabilisation of negative charge (Section 1.4).

The data in Table 1.3 loosely supports the assignments of functional groups by Testa et al. displayed in Table 1.1. The designation of $\mathrm{C}(\mathrm{O})$-aryl as strongly destabilising is supported by data from compounds $\mathbf{1 . 1}$ and 1.2 (amfepramone and cathinone). It was determined that these compounds undergo racemisation through an $\mathrm{S}_{\mathrm{E}} \mathrm{l}$ mechanism, with half lives of approximately 20 and 90 minutes respectively (in $\mathrm{D}_{2} \mathrm{O}$ based 0.2 M phosphate buffers, at 37 ${ }^{\circ} \mathrm{C}$ ). ${ }^{57}$ By the assignments in Table 1.1, both compounds have one neutral substituent (methyl), one destabilising (amine groups, primary for 1.2, tertiary for 1.1) and one strongly destabilising $\left(\mathrm{C}(\mathrm{O}) \mathrm{C}_{6} \mathrm{H}_{5}\right)$. In comparison, for 1.4 (clopidogrel) the rate constants are 2-3 orders of magnitude lower. Compound 1.4 has, by Testa's classifications, two destabilising groups (a tertiary amine and an aryl group) and one strongly destabilising group (methyl ester). This suggests that a methyl ester is (despite its classification in Table 1.1) less destabilising than an aryl ketone. This would also be consistent with the far lower $\mathrm{p} K_{\mathrm{a}}$ value found for a ketone than a methyl ester by Richards et al. (Table 1.2). Compound 1.3 (1,2-Diphenylpropan-1-one) also contains an aryl ketone and racemises much faster than 1.4, however, as the rate constants were determined in ethanol solution rather than water, direct comparison is inappropriate.

Reist et al. ${ }^{57}$ attributed the difference in racemisation rates of $\mathbf{1 . 1}$ and $\mathbf{1 . 2}$ to the different $\mathrm{p} K_{\mathrm{a}}$ values of the amines of 8.79 and 8.37 , respectively. They conclude that the greater basicity of 1.1 means that a larger fraction of its molecules will be protonated (and hence more electron withdrawing and configurationally destabilising) than 1.2 at the pH at which the experiments were carried out. However, the rate constants were determined at pH 7.4 . At this pH the vast majority of molecules of both $\mathbf{1 . 1}$ and $\mathbf{1 . 2}$ will be protonated, suggesting that the protonation state is unlikely to be responsible. $\mathrm{p} K_{\mathrm{a}}$ values determined by Rios et al. ${ }^{50}$ (Scheme 1.13) suggest that the $\alpha$-proton of a positively charged amine is more acidic for more substituted amines (i.e. the $\mathrm{p} K_{\mathrm{a}}$ for the $\alpha$-proton is lower for a compound containing $\mathrm{Me}_{3} \mathrm{~N}^{+}$than for $\mathrm{H}_{3} \mathrm{~N}^{+}$). This difference is attributed to two effects: (1) hydrogen bond formation between
$\mathrm{H}_{3} \mathrm{~N}^{+}$and solvent, which diffuses positive charge away from nitrogen and onto solvent molecules and decreases interaction between charges; (2) methyl groups of $\mathrm{Me}_{3} \mathrm{~N}^{+}$reduce the dielectric constant of the local medium through which the electrostatic interactions occur, giving greater stabilisation of the negative charge. ${ }^{72,73}$ It is also noted that a lower $\mathrm{p} K_{\mathrm{a}}$ for a proton $\alpha$ to $\mathrm{Me}_{3} \mathrm{~N}^{+}$than for $\mathrm{H}_{3} \mathrm{~N}^{+}$is consistent with the $\sigma_{\mathrm{I}}$ (field effect) values of 0.92 and 0.60 respectively reported by Hine, ${ }^{74}$ although other sources ${ }^{75}$ record field effects to be nearly the same for both substituents.

Reist et al. ${ }^{33}$ determined the rates of H/D exchange for a series of substituted hydantoins. By comparison with the rate of racemisation for some of the compounds, they concluded that hydantoins undergo racemisation through an $\mathrm{S}_{\mathrm{E}} 2$ mechanism, whereby deuteration proceeds with chiral inversion (Section 1.3). To the best of our knowledge, this is the only reported example of an $\mathrm{S}_{\mathrm{E}} 2$ mechanism of racemisation found in the literature, although recent results suggest the reaction may follow an $\mathrm{S}_{\mathrm{E}} 1$ mechanism. ${ }^{76}$ The rate constants of H/D exchange for the series of hydantoins can be used to analyse the effect of substituents on the lability of the proton bound to the stereogenic centre (Table 1.4).

Table 1.4: Rate constants of H/D exchange and racemisation of hydantoins, reproduced from reference 33.

${ }^{a}$ determined in a mixture of $\mathrm{D}_{2} \mathrm{O}$ phosphate buffer (pD 7.4, 0.1M, $\mathrm{I}=0.22$ ) and $\left(\mathrm{d}^{6}\right) \mathrm{DMSO}$ in proportion 1:1 ( $v / v)$ at $50^{\circ} \mathrm{C}$. ${ }^{\mathrm{b}}$ determined in a mixture of phosphate buffer $(\mathrm{pH} 7.4,0.1 \mathrm{M}, \mathrm{I}=$ 0.22 ) and DMSO in proportion $1: 1(v / v)$ at $50^{\circ} \mathrm{C}$

The rate constant for H/D exchange determined for phenyl substituted hydantoin is far larger than any other. This is consistent with the designation of aryl groups as destabilising. Table 1.1 also suggests NRR' substituents are destabilising. However, the rate constant of the amido
substituent in Table 1.4 is two orders of magnitude smaller than that of the phenyl substituent. This suggests that the assignments made by Testa et al. are qualitative rather than quantitative, and there is much variation within the general classification as 'destabilising'. Comparison of the other rate constants provided in Table 1.3 with those in Table 1.4 is difficult. Compared with most of the other data sets the H/D exchange of hydantoins were studied at a higher temperature, and using DMSO as a co-solvent (for solubility) which will affect the observed rate constants.

Compounds 1.6 and 1.7 have similar structures to 1.5 (5-phenylhydantoin). Both are of the type R''R'RC-H and racemisation is base catalysed. The rate constants for racemisation, however, are around two orders of magnitude less than for $\mathbf{1 . 5}$. This may be due to the different conditions or due to the differences in structure. For example, $\mathbf{1 . 6}$ and $\mathbf{1 . 7}$ do not have the adjacent carbonyl as found in 1.5. Also of note is the amide substitution on the phenyl ring adjacent the stereogenic centre in $\mathbf{1 . 6}$ and 1.7. The electron-donating nature of the amide group will destabilise any negative charge built up at the stereogenic centre during racemisation and hence reduce the rate.

Table 1.3 also provides evidence supporting the classification of a carboxylate group as configurationally stabilising. $\mathbf{1 . 4}$ contains a methyl ester and racemises. However, $\mathbf{1 . 4}$ also undergoes hydrolysis to the carboxylate after which no further racemisation is observed. ${ }^{59}$ This is due to the negative charge already existing on the carboxylate.

It is interesting to consider ibuprofen (and indeed, all profens) at this point, as ibuprofen also has a carboxylate substituent on the stereogenic centre. Profens are known to undergo racemisation in vivo and a substantial literature exists documenting this. ${ }^{77-81}$ However, profen racemisation occurs via an enzymatic conversion of the carboxylate to its acyl CoA thioesters which increases the lability of the proton bound to the stereogenic centre and chiral inversion occurs. ${ }^{70 .}{ }^{82.83}$ When the ester is hydrolysed, the starting material is recovered but any enantiopurity is lost. Similarly, in order to racemise naproxen (another profen), Noorduin et al. ${ }^{84}$ first converted the carboxylate into methyl or ethyl esters.

Direct racemisation of ibuprofen without ester formation, required harsh conditions: high DMSO concentration, very high temperatures $\left(100^{\circ} \mathrm{C}\right)$ and a very basic reaction medium $(0.5$ $\mathrm{M} \mathrm{NaOH}){ }^{85}$ The racemisation of free amino acids by Smith and Sivaua ${ }^{40}$ also required temperatures in excess of $100^{\circ} \mathrm{C}$. These results support the assignment of a carboxylate as configurationally stabilising under physiological conditions. However, the case of ibuprofen shows the importance of distinguishing between in vivo and in vitro testing.

Compound 1.18 (RS-10085) contains 3 stereogenic centres of type R''R'RC-H. Although epimerisation rates were not determined, Gu and Strickley ${ }^{71}$ noted that only one of the three stereogenic centres showed any chiral instability. Comparison of the functional groups present on each stereogenic centre provides a rationale for this observation. The only stereogenic centre to show any chiral instability has amine (destabilising), alkyl (neutral) and ester (strongly destabilising) substituents. The other two stereocentres have an amine (destabilising), an amide (destabilising) and a methyl (neutral) substituent and an amine (destabilising), a methyl (neutral) and a carboxylate (stabilising) substituent. These observations provide general support for Testa's conclusion that either three destabilising substituents or two destabilising substituents (with one strongly so) and one neutral substituent must be present in order to see configurational instability in a stereogenic centre of type R''R'RC-H under physiological conditions.

### 1.5.2 Other Mechanisms of Racemisation

Stereogenic centres of the type R''R'RC-H with an adjacent carbonyl may also be susceptible to racemisation in acidic conditions. Protonation of the carbonyl followed by keto-enol tautomerism will result in loss of enantiopurity (Scheme 1.16). ${ }^{86}$

Scheme 1.16: Acid-catalysed racemisation of $\alpha$-carbonyl stereocentres.
Similarly, acid-catalysed racemisation via imine-enamine tautomerism has been observed for 1.10 (9-hydroxyrisperidone) in aqueous conditions (Scheme 1.17). ${ }^{62}$

Scheme 1.17: Mechanism of racemisation of 9-hydroxyrisperidone (1.10).
General-acid catalysis by phosphate was observed for racemisation of 1.10. The racemisation of this compound also showed some general-base catalysis, probably through proton abstraction, but this required severely basic conditions.

Compounds with a stereogenic centre of the form R''R'RC-OH have been shown to racemise through protonation of the alcohol followed by dehydration to give an achiral carbocation intermediate which can be hydroxylated on either face. Such a mechanism has been observed for catecholamines, such as $\mathbf{1 . 1 2}$ (adrenaline) (Scheme 1.18). ${ }^{65}$

Scheme 1.18: Acid-catalysed racemisation mechanism of adrenaline (1.12).

For 1.12, the electron-donating hydroxy substituent on the phenyl group adjacent to the stereogenic centre helps stabilise the positive charge build up during racemisation. Removal of the $p-\mathrm{OH}$ group results in a drop in the rate constant of racemisation by three orders of magnitude.
1.11 (ibutilide) and $\mathbf{1 . 1 6}$ (chlorthalidone) also contain stereogenic centres of the type R''R'RC-OH. They too show acid-catalysed racemisation as depicted in Scheme 1.18 , with protonation of the alcohol followed by dehydration giving an achiral cationic intermediate which is hydroxylised on either face. $\mathbf{1 . 1 1}$ and $\mathbf{1 . 1 6}$ also undergo competing reactions that complicate the issue. For example, $\mathbf{1 . 1 1}$ also undergoes intramolecular nucleophilic attack by nitrogen at the stereogenic centre (Scheme 1.19).

Scheme 1.19: Reactions of ibutilide (1.11).
Lambert et al. ${ }^{64}$ concluded that some of the observed racemisation goes through the carbocation intermediate depicted in Scheme 1.19. This can be stabilised by electron donation from the para amine substituent on the adjacent aryl group (not depicted). However, there is also direct $\mathrm{S}_{\mathrm{N}} 2$ racemisation through intramolecular nucleophilic attack by the amine with a hydroxyl leaving group.

Lamparter et al. ${ }^{69}$ observed a U-shaped pH rate profile for the racemisation of 1.16 and observed both acid and base catalysis. Under acidic conditions protonation of the alcohol caused racemisation as depicted in Scheme 1.20a, but under basic conditions deprotonation of the alcohol group leads to ring opening to give an achiral intermediate (Scheme 1.20b).
a)

$$
\mathrm{R}=-\mathrm{SO}_{2} \mathrm{NH}_{2}
$$

b)

Scheme 1.20: Racemisation mechanisms of chlorthalidone (1.16) catalysed by a) acid, b) base.

The drug 1.15 (oxazepam) undergoes rapid racemisation with a half-life of around 3 minutes at ambient temperature in aqueous media. ${ }^{68,87,88}$ As the rate of racemisation is fast in comparison to its pharmacologically active period, it has been suggested to regard $\mathbf{1 . 1 5}$ as 'a single compound existing in two very rapidly interconverting chiral states, ${ }^{89} \mathbf{1 . 1 5}$ undergoes racemisation through the breaking and reforming of a bond adjacent the chiral centre. As the bond being broken is part of a seven membered ring, the reformation is not entropically demanding. This leads to a tautomeric equilibrium depicted in Scheme 1.21.

Scheme 1.21: Racemisation of oxazepam (1.15).
1.15 undergoes racemisation under acidic and basic aqueous solutions. In acidic solutions, protonation of the imine may catalyse the rearrangement whereas in basic solutions removal of the hydroxyl proton may be base catalysed.

### 1.6 Acid and Base Catalysis ${ }^{90}$

The aqueous nature of the blood stream and the presence within it of endogenous buffers such as proteins, amines and anions such as thiolates, phosphate and bicarbonate means that any acid or base catalysis of racemisation should be understood. ${ }^{89}$

### 1.6.1 Acid Catalysis

There are several examples in the literature of racemisation reactions catalysed by acid. ${ }^{64,91-93}$ Catalysis of a reaction by $\mathrm{H}_{3} \mathrm{O}^{+}$ions only is referred to as specific-acid catalysis. In aqueous solutions, specific-acid-catalysed reactions are found to have pseudo first-order rate constants (eqn 1.3).

$$
\begin{equation*}
-\frac{\mathrm{d}[\mathrm{R}]}{\mathrm{d} t}=k_{\mathrm{obs}} \cdot[\mathrm{R}] \tag{1.3}
\end{equation*}
$$

where [ R ] is the reactant concentration and $k_{\text {obs }}$ is the observed rate constant.
The observed rate constant for specific-acid-catalysed reactions can be expressed in the form of eqn (1.4).

$$
\begin{equation*}
k_{\text {obs }}=k_{0}+k_{\mathrm{H}} \cdot\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] \tag{1.4}
\end{equation*}
$$

where $k_{\text {obs }}$ is the observed rate constant, $k_{0}$ is the rate constant for the uncatalysed reaction and $k_{\mathrm{H}}$ is the rate constant for the reaction catalysed by $\mathrm{H}_{3} \mathrm{O}^{+}$, and $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$is the concentration of $\mathrm{H}_{3} \mathrm{O}^{+}$.
$k_{0}$ and $k_{\mathrm{H}}$ for specific-acid-catalysed reactions can be determined by plotting $k_{\mathrm{obs}}$ against $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$for the reaction at various acid concentrations. The slope of the line corresponds to $k_{\mathrm{H}}$ and the intercept, where $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right.$] equals 0 , is $k_{0}$.

Catalysis by an un-ionised acid A-H is known as general-acid catalysis. General-acid catalysis will add an extra term to the expression for the rate constant for the reaction for each catalytically active acid present, resulting in eqn (1.5).

$$
\begin{equation*}
k_{\text {obs }}=k_{0}+k_{\mathrm{H}} \cdot\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]+\sum k_{\mathrm{AH}} \cdot[\mathrm{AH}] \tag{1.5}
\end{equation*}
$$

where $k_{\mathrm{obs}}$ is the observed rate constant, $k_{0}$ is the rate constant for the uncatalysed reaction, $k_{\mathrm{H}}$ is the rate constant for the reaction catalysed by $\mathrm{H}_{3} \mathrm{O}^{+}, k_{\mathrm{AH}}$ is the rate constant for the reaction catalysed by the general acid AH , and $\Sigma k_{\mathrm{AH}}[\mathrm{AH}]$ is the sum over the contributions of all catalytically active acids present.

A general-acid-catalysed reaction can be differentiated from a specific-acid-catalysed reaction, by determining the relationship between $k_{\mathrm{obs}}$ and $[\mathrm{AH}]$ at a constant pH . A specific-acid-catalysed reaction will give a horizontal line, whereas general-acid-catalysed reactions will give a slope. The intercept, where general acid concentration is 0 , corresponds to $k_{0}+k_{\mathrm{H}}\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and the slope of the line corresponds to $k_{\mathrm{AH}}$.

### 1.6.2 Base Catalysis

Base-catalysed racemisations are well documented in the literature. ${ }^{40,57,61,85,94,95}$ Base catalysis is generally a result of proton abstraction by base from stereocentres of the type R' ${ }^{\prime}$ ' ${ }^{\prime}$ C- H through either an $\mathrm{S}_{\mathrm{E}} 1$ or $\mathrm{S}_{\mathrm{E}} 2$ mechanism (Section 1.3).

A reaction which takes place that is catalysed by $\mathrm{OH}^{-}$but not by any other bases present is described as specific-base catalysed, analogous to specific-acid catalysis. The rate law for such reactions is described in eqn (1.6).

$$
\begin{equation*}
-\frac{\mathrm{d}[\mathrm{R}]}{\mathrm{d} t}=k_{\mathrm{obs}} \cdot[\mathrm{R}] \tag{1.6}
\end{equation*}
$$

The pseudo first-order rate constant for such reactions can be expressed as eqn (1.7).

$$
\begin{equation*}
k_{\mathrm{obs}}=k_{0}+k_{\mathrm{OH}} \cdot\left[\mathrm{OH}^{-}\right] \tag{1.7}
\end{equation*}
$$

where $k_{\text {obs }}$ is the observed rate constant, $k_{0}$ is the rate constant for the uncatalysed reaction and $k_{\mathrm{OH}}$ is the rate constant for the reaction catalysed by $\mathrm{OH}^{-}$.

Akin to specific-acid-catalysed reactions, a plot of $k_{\text {obs }}$ against $\left[\mathrm{OH}^{-}\right]$for specific basecatalysed reactions gives a straight line with intercept $k_{0}$, and gradient $k_{\mathrm{OH}}$.

If a reaction is catalysed by any base, it is general-base catalysed. The observed rate constant for such reactions is given by eqn (1.8).

$$
\begin{equation*}
k_{\mathrm{obs}}=k_{0}+k_{\mathrm{OH}} \cdot\left[\mathrm{OH}^{-}\right]+\sum k_{\mathrm{B}} \cdot[\mathrm{~B}] \tag{1.8}
\end{equation*}
$$

where $k_{\text {obs }}$ is the observed rate constant, $k_{0}$ is the rate constant for the uncatalysed reaction, $k_{\mathrm{OH}}$ is the rate constant for the reaction catalysed by $\mathrm{OH}^{-}, k_{\mathrm{B}}$ is the rate constant for the
reaction catalysed by general base B , and $\Sigma k_{\mathrm{B}}$.[B] is the sum over the contributions of all catalytically active bases present.

A general-base-catalysed reaction is catalysed by any base. As such, each general base present will need to be included in the sum function in eqn (1.8). This is important when a general base may exist in more than form, such as phosphate in different protonation states.

General-base-catalysed reactions are distinguished from specific-base-catalysed reactions in the same manner as specific- and general-acid-catalysed reactions are distinguished. A plot of $k_{\mathrm{obs}}$ against [B] at constant pH will give a horizontal line for specific-base-catalysed reactions and a slope for general-base-catalysed reactions with intercept $k_{0}+k_{\mathrm{OH}}\left[\mathrm{OH}^{-}\right]$and gradient $k_{\mathrm{B}}$.

### 1.7 Kinetic Isotope Effects ${ }^{96}$

In studying chemical reactions, the presence of kinetic isotope effects (KIEs) can offer insight into the mechanism by which a reaction can take place. It is known that substitution of an atom within a molecule by an isotope of the same element does not affect the chemistry of the compound. Such a compound will undergo the same chemical reactions, via the same mechanisms, regardless of the change in isotope. However, the rate (or equilibrium) constant for the reaction may become smaller or larger due to the isotopic substitution. It is this change in rate constant, or lack thereof, that provides information on the mechanism of reaction.

The principles behind the KIE are best discussed for the example of a simple diatomic molecule, $\mathrm{H}-\mathrm{X}$, the zero-point energy $\left(\varepsilon_{0}\right)$ of which is given by eqn (1.9).

$$
\begin{equation*}
\varepsilon_{0}=0.5 h \nu \tag{1.9}
\end{equation*}
$$

where $v$ is the vibrational frequency and $h$ is Planck's constant.
As eqn (1.9) shows, the zero-point energy is dependent on the molecule's vibrational frequency. Although increasing the mass of an atom in a molecule by addition of a neutron to the nucleus has no effect on the bonding within the molecule, it does affect its vibrational properties. The vibrational frequency of $\mathrm{H}-\mathrm{X}$ (where X is an atom much heavier than hydrogen) is given by eqn (1.10).

$$
\begin{equation*}
v=\frac{1}{2 \pi} \sqrt{\frac{\kappa}{\mu_{\mathrm{HX}}}} \tag{1.10}
\end{equation*}
$$

where $\kappa$ is the force constant of the bond and $\mu_{\mathrm{HX}}$ is the reduced mass of the molecule.

The reduced mass for a diatomic molecule $\mathrm{H}-\mathrm{X}$ is given by eqn (1.11).

$$
\begin{equation*}
\mu_{\mathrm{HX}}=\frac{m_{\mathrm{H}} \cdot m_{\mathrm{X}}}{\left(m_{\mathrm{H}}+m_{\mathrm{X}}\right)} \tag{1.11}
\end{equation*}
$$

where $m_{\mathrm{H}}$ is the mass of H and $m_{\mathrm{X}}$ is the mass of X .
If $m_{\mathrm{X}} \gg m_{\mathrm{H}}$, the reduced mass of $\mathrm{H}-\mathrm{X}$ is approximately equal to 1 . However, for the deuterated equivalent (D-X) the reduced mass is approximately equal to 2 . From the reduced masses and eqn (1.11), the resulting molecular vibration of DX is lower than that of HX (eqn 1.12).

$$
\begin{equation*}
\frac{v_{\mathrm{HX}}}{v_{\mathrm{DX}}}=\sqrt{\frac{\mu_{\mathrm{DX}}}{\mu_{\mathrm{HX}}}} \approx \sqrt{2} \approx 1.41 \tag{1.12}
\end{equation*}
$$

This difference in vibrational frequencies is the basis for the KIE. As the vibrational frequency for $\mathrm{D}-\mathrm{X}$ will be lower than that of $\mathrm{H}-\mathrm{X}$ (eqn 1.12), the zero-point energy will also be lower (Figure 1.1).

Figure 1.1: Enharmonic oscillator potential-energy diagram for diatomic molecules $H-X$ and $D-X$ (where the mass of $X \gg H$ ). $D_{0}(H X)=$ dissociation energy of $H-X, D_{0}(D X)=$ dissociation energy of $D-X$.

Figure 1.1 shows that a greater amount of energy is required to break the $\mathrm{D}-\mathrm{X}$ bond than is required to break the $\mathrm{H}-\mathrm{X}$ bond. This is the origin of the KIE. For reactions where the rate-
determining-step involves breaking of a bond to a proton, the ratio $k_{\mathrm{H}} / k_{\mathrm{D}}$ is therefore greater than 1 , where $k_{\mathrm{H}}$ is the rate constant for the protonated reaction and $k_{\mathrm{D}}$ is the rate constant for the deuterated reaction. KIEs greater than 1 are known as a normal KIE, and are typically around 2-3. An example of a normal KIE is the dehydrogenation of propanol (Scheme 1.22).

Scheme 1.22: Dehydrogenation of propan-1-ol by chromium trioxide, where $k_{\mathrm{H}} / k_{\mathrm{D}}=7 .{ }^{96}$

Instances where $k_{\mathrm{H}} / k_{\mathrm{D}}<1$ are known as an inverse KIE. These occur when the force field of a vibration involving the isotopically substituted atom increases as the reaction progresses. This results in the vibrational potential energy curve of the activated complex becoming steeper than that of the reactant, and the gap between the ${ }^{1} \mathrm{H}$ energy level is larger than that between the ${ }^{2} \mathrm{H}$ energy levels.

Heavy atom KIEs may be observed when an element other than hydrogen is isotopically substituted (e.g. ${ }^{35} \mathrm{Cl}$ and ${ }^{37} \mathrm{Cl}$ ). However, as the proportional difference in the reduced masses is far lower for isotopes of heavy atoms than for hydrogen, any KIE will be smaller in magnitude.

Isotopic variation of a molecule in positions other than the site of reaction may also give different rate constants. This is known as a secondary KIE. Magnitudes are generally far lower than for primary KIEs, typically around $0.80-1.25$, and are dependent on the distance between the site of reaction and the isotopically varied atom.

KIEs may also be seen when the solvent in which the reaction is taking place is isotopically substituted. A common example is performing a reaction in both $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{D}_{2} \mathrm{O}$. Solvent KIEs may be a result of the solvent being a reagent in the reaction, or result from different solvation properties of the isotopically substituted solvent.

### 1.8 Linear Free-Energy Relationships

### 1.8.1 The Brønsted Catalysis Law

The Brønsted catalysis law is a linear free energy relationship (LFER) that describes the relationship between acid or base strength with its catalytic ability in general-acid and -base
catalysis (see Section 1.6). The Brønsted relationship is described by eqn (1.13) for generalacid catalysis and by eqn (1.14) for general-base catalysis.

$$
\begin{align*}
& \log k_{\mathrm{AH}}=-\alpha \cdot \mathrm{p} K_{\mathrm{AH}}+\text { constant }  \tag{1.13}\\
& \log k_{\mathrm{B}}=\beta \cdot \mathrm{p} K_{\mathrm{BH}}+\text { constant } \tag{1.14}
\end{align*}
$$

where $k_{\mathrm{AH}}$ is the second-order rate constant for the reaction catalysed by the general acid AH, $K_{\mathrm{AH}}$ is the acidity constant of $\mathrm{AH}, \alpha$ is the Brønsted factor for catalysis by general acids of the reaction under scrutiny, $k_{\mathrm{B}}$ is the rate constant for the reaction catalysed by the general base B , $K_{\mathrm{BH}}$ is the acidity constant of the conjugate acid of B and $\beta$ is the Brønsted factor for catalysis by general bases of the reaction under scrutiny.

Values for $\alpha$ or $\beta$ are determined by measuring $k_{\mathrm{AH}}$ or $k_{\mathrm{B}}$ for reaction for a series of acid or base catalysts. A logarithmic plot of the resulting rate constants against the $\mathrm{p} K_{\mathrm{AH}}$ or $\mathrm{p} K_{\mathrm{BH}}$ of the catalyst used in each case should give a straight line with gradient $\alpha$ or $\beta$ (Figure 1.2).

Figure 1.2: Example of a Brønsted plot, with gradient $-\alpha$ or $\beta$.
The Brønsted $\alpha$ and $\beta$ coefficients quantify how sensitive the catalysed reaction is to the strength of the acid or base catalysts, and is typically in the range $0-1$ for reactions carried out in water.

When $\alpha$ and $\beta$ are close to zero or one, the values are difficult to determine experimentally. When close to zero, catalysis is insensitive to the strength of the catalyst, meaning the reaction will take place by pathways in proportion to the relative concentrations of each acid or base present. Therefore, in aqueous conditions the reaction will be almost exclusively
solvent induced, any acid or base catalysis will be difficult to observe and the reaction will appear uncatalysed. Conversely, as $\alpha$ and $\beta$ tend to one the reaction is very sensitive to the catalyst strength. The majority of the reaction will take place by the strongest acid or base present, $\mathrm{H}_{3} \mathrm{O}^{+}$or $\mathrm{OH}^{-}$respectively in water, and the reaction will thus appear to be specificacid or -base catalysed.

The physical reason for the LFER and the traditional interpretation of Brønsted $\alpha$ or $\beta$ is illustrated by a potential energy diagram (Figure 1.3).

Figure 1.3: Reaction profile for proton abstraction by base. Reactant AH is the same for both curves, with base B modified to a stronger base $\mathrm{B}^{\prime} . \Delta G^{\Theta^{\dagger}}$ is the standard molar Gibbs energy of activation and $\Delta G^{\Theta}$ is the standard molar Gibbs energy of reaction

Modifying the base results in a lowering of the activation energy. The difference in activation energies for the two bases is denoted in Figure 1.3 by $\delta \Delta G^{\Theta \ddagger}$. The Brønsted parameter ( $\beta$ in this case) is the proportionality constant between $\delta \Delta G^{\ominus}$ and $\delta \Delta G^{\ominus \ddagger}$ (eqn 1.15).

$$
\begin{equation*}
\delta \Delta G^{\ominus \dagger}=\beta \cdot \delta \Delta G^{\ominus} \tag{1.15}
\end{equation*}
$$

In the traditional interpretation of Brønsted plots, $\alpha$ or $\beta$ describe the degree of proton transfer taking place at the transition state. As $\alpha$ or $\beta$ tend to zero, the transition state is similar in structure to reactants and little or no proton transfer has occurred. As $\alpha$ or $\beta$ tend to one, the transition state is similar in structure to the products and proton transfer is almost complete.

### 1.8.2 The Hammett Equation ${ }^{97-99}$

The Hammett equation is a Linear Free Energy Relationship (LFER) which can provide insight into the mechanism by which a specific reaction of a series of substituted aromatic compounds takes place. A series of compounds, differently substituted in the meta and para positions but with a common reaction site, will show differences in their reactivity at the common site dependent on the substituent nature. An equation providing a quantitative link between processes sharing a common development of charge was first proposed by Louis P. Hammett in 1937 based on the varying acidities of substituted benzoic acid derivatives. ${ }^{100}$

Scheme 1.23: Dissociation of benzoic acid derivatives.
For the deprotonation of benzoic acids, electron-withdrawing substituents stabilise the negative charge on the carboxylate and hence the equilibrium lies further to the right-handside of Scheme 1.23. Electron-donating substituents destabilise the negative charge and hence equilibrium lies further to the left. Taking the deprotonation of benzoic acids as a reference reaction, the basic equation describing the relationship between electronic substituent effect and equilibrium constants is given by eqn (1.16).

$$
\begin{equation*}
\log \left\{\frac{K_{\mathrm{X}}}{K_{0}}\right\}=\mathscr{P} \tag{1.16}
\end{equation*}
$$

where $K_{\mathrm{X}}$ is the equilibrium constant of reaction for the compound with aromatic substituent $\mathrm{X}, K_{0}$ is the equilibrium constant of reaction for the unsubstituted compound, $\sigma$ is the substituent constant for substituent X and $\rho$ is the reaction constant.

The reaction constant, $\rho$, was arbitrarily set to 1 for the dissociation of benzoic acids in water at $25{ }^{\circ} \mathrm{C}$. This allows for each substituent X , the assignment of a substituent constant, $\sigma$, which quantifies its electron-withdrawing or -donating capability. The same substituent will have a different $\sigma$ value depending on whether it is in the meta- ( $\sigma_{\mathrm{m}}$ ) or para-position ( $\sigma_{\mathrm{p}}$ ) (ortho substituents are excluded as steric effects become a factor as well as the electronic factors). Compared to no substitution, electron-withdrawing substituents have a positive $\sigma$ value; electron-donating substituents have a negative $\sigma$ value (Table 1.5).

Table 1.5: List of example Hammett substituent constants. ${ }^{75}$ The applicability of $\sigma_{\mathrm{p}}{ }^{-}$and $\sigma_{\mathrm{p}}{ }^{+}$ substituent constants is outlined in Sections 1.8.2.2.1 and 1.8.2.2.2.

## Substituent Constants

| Substituent | Substituent Constants |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | $\sigma_{\mathrm{m}}$ | $\sigma_{\mathrm{p}}$ | $\sigma_{\mathrm{p}}{ }^{-}$ | $\sigma_{\mathrm{p}}{ }^{+}$ |
| $\mathrm{NO}_{2}$ | 0.71 | 0.78 | 1.27 | 0.79 |
| $\mathrm{CF}_{3}$ | 0.43 | 0.54 | 0.65 | 0.61 |
| COOH | 0.37 | 0.45 | 0.77 | 0.42 |
| COOMe | 0.37 | 0.45 | 0.75 | 0.49 |
| Cl | 0.37 | 0.23 | 0.19 | 0.11 |
| F | 0.34 | 0.06 | -0.03 | -0.07 |
| OMe | 0.12 | -0.27 | -0.26 | -0.78 |
| OH | 0.12 | -0.37 | -0.37 | -0.92 |
| H | 0.00 | 0.00 | 0.00 | 0.00 |
| Et | -0.07 | -0.15 | -0.19 | -0.30 |
| Me | -0.07 | -0.17 | -0.17 | -0.31 |
| $\mathrm{COO}^{-}$ | -0.10 | 0.00 | 0.30 | -0.02 |
| $\mathrm{NH}_{2}$ | -0.16 | -0.66 | -0.15 | -1.30 |

Using these substituent constants, the $\rho$ value of any reaction can be determined experimentally. A positive $\rho$ value informs us that negative charge is built up during the reaction or a positive charge is removed; a negative value tells us that positive charge is built up or a negative charge is removed.

The Hammett equation is most frequently used for analysis of rate constants for reactions of a series of substituted aromatic compounds (eqn 1.17).

$$
\begin{equation*}
\log \left\{\frac{k_{\mathrm{x}}}{k_{0}}\right\}=\varnothing \rho \tag{1.17}
\end{equation*}
$$

where $k_{\mathrm{X}}$ is the rate constant of reaction for the compound with aromatic substituent $\mathrm{X}, k_{0}$ is the rate constant of reaction for the unsubstituted compound, $\sigma$ is the substituent constant for substituent X and $\rho$ is the reaction constant to be determined.

Again, the sign and magnitude of $\rho$ affords information on the nature and magnitude of any charge built up (or removed) on the activated complex during the reaction, and therefore informs us about the mechanism by which the reaction takes place.

The information that can be retrieved from $\rho$ is illustrated by the hydrolysis reaction of substituted phenyl diphenylphosphinates, catalysed by imidazole (Scheme 1.24). ${ }^{101}$

Scheme 1.24: Hydrolysis of substituted phenyl diphenylphosphinates, catalysed by imidazole.

The rate constants for the differently substituted esters are listed in Table 1.6.
Table 1.6: Rates of hydrolysis of substituted phenyl diphenylphosphinates catalysed by imidazole in $10 \%$ dioxane in water, $\mathrm{pH} 8.12,55^{\circ} \mathrm{C}$ (data from reference 100 ).

| Substituent X | $\sigma$ | $k \times 10^{3} / \mathrm{M}^{-1} \mathrm{~s}^{-1}$ | $\log \frac{k_{\mathrm{X}}}{k_{0}}$ |
| :---: | :---: | :---: | :---: |
| $p-\mathrm{NO}_{2}$ | 0.78 | $4.880 \pm 0.080$ | 2.130 |
| $m-\mathrm{NO}_{2}$ | 0.71 | $2.100 \pm 0.030$ | 1.764 |
| $p-\mathrm{C}(\mathrm{O}) \mathrm{Me}$ | 0.50 | $0.857 \pm 0.008$ | 1.374 |
| $p-\mathrm{Cl}$ | 0.23 | $0.141 \pm 0.0003$ | 0.590 |
| H | 0 | $0.0362 \pm 0.0002$ | 0 |

A Hammett plot of the data from Table 1.6 is displayed in Figure 1.4.

Figure 1.4: Hammett plot for the imidazole catalysed hydrolysis of substituted phenyl diphenylphosphinates in $10 \%$ dioxane in water, pH 8.12 , $55^{\circ} \mathrm{C}, \rho=2.64$.

The sign and magnitude of $\rho$ suggests that a significant extent of negative charge is built up on the activated complex during hydrolysis (Scheme 1.25).

Scheme 1.25: Negative charge build up during hydrolysis of phenyl diphenylphosphinates.

This negative charge is stabilised by electron withdrawing groups. This means $\Delta G^{\ddagger}$ is lowered and hence the reaction takes place with a higher rate constant.

### 1.8.2.1 Factors Affecting $\rho$

### 1.8.2.1.1 Distance Between Reaction Site and Aromatic Substituent

The number of bonds in a molecule between the site of reaction and the substituted aromatic ring will affect the magnitude of $\rho$. Increased distance between the reaction site and the substituted aromatic ring will diminish the transmission of any electronic effect, and reduce the magnitude of $\rho$. This is illustrated by the dissociation of aromatic acids. The original

Hammett $\sigma$ constants are based on the equilibrium constants for dissociation of benzoic acids in water at $25^{\circ} \mathrm{C}$. Moving the site of dissociation away from the site of substitution lowers the $\rho$ value as displayed in Table 1.7.

Table 1.7: Hammett $\rho$ values for the dissociation of aromatic acids in $\mathrm{H}_{2} \mathrm{O}$ at $25^{\circ} \mathrm{C} .{ }^{102}$

| $\mathbf{A c i d}^{\mathbf{a}}$ |  | $\boldsymbol{\rho}$ |
| :---: | :---: | :---: |
|  |  | 1.00 |
| $\mathrm{ArCH}_{2} \mathrm{COOH}$ |  | 0.49 |
| $\mathrm{ArCH}_{2} \mathrm{CH}_{2} \mathrm{COOH}$ |  | 0.21 |

[^3]
### 1.8.2.1.2 Temperature Dependence of $\rho$

The temperature dependence of $\rho$ has been subject to much debate. Many studies have suggested that the reaction constant $\rho$ varies with temperature, ${ }^{103-106}$ in one manner or another. The effect of the reaction medium and temperature on $\rho$ values has been described by eqn (1.18). ${ }^{100,107,108}$

$$
\begin{equation*}
\rho=\left(\frac{\mathrm{A}+(\mathrm{B} / \mathrm{D})}{\mathrm{RT}}\right) \tag{1.18}
\end{equation*}
$$

where, $A$ and $B$ describe the susceptibility of the reaction to polar effects independent and dependent on the reaction medium, $D$ is the dielectric constant of the medium, $R$ is the gas constant and $T$ is the temperature.

Eqn (1.18) suggests that the magnitude of $\rho$ is inversely proportional to $T$. As a result, we would expect to see the $\rho$ value of a reaction decrease if the temperature is increased. However, eqn (1.18) and the dependence of $\rho$ on $T^{1}$ has not been unequivocally accepted. ${ }^{109-}$ ${ }^{111}$ An example of a lack of temperature dependence of $\rho$ is provided by the racemisation of phenylglycines in aqueous conditions, as studied by Smith and Sivakua. ${ }^{40}$ They found identical $\rho$ values of 1.15 for the reaction at both 80 and $110{ }^{\circ} \mathrm{C}$, and concluded that temperature was not a major factor for the $\rho$ value.

### 1.8.2.1.3 Non-linearity

For some reactions, the Hammett relationship does not apply and a non-linear Hammett plot is found. A non-linear Hammett plot may indicate that the LFER has broken down, potentially
as a result of a change in mechanism, for example from an $\mathrm{S}_{\mathrm{N}} 2$ to an $\mathrm{S}_{\mathrm{N}} 1$ or $\mathrm{S}_{\mathrm{A}} \mathrm{N}$ mechanism. ${ }^{112}$ The application of modified Hammett substituents in certain circumstances can also be used to explain and circumvent non-linearity in a Hammett plot.

### 1.8.2.2 Modifications of the Hammett Equation

In some circumstances, the Hammett $\sigma$ constants require modification for certain substituents. In order for a LFER to be valid, the change from the reference compound to the modified compound (in this case from the unsubstituted to substituted compound) should be qualitatively the same on the test reaction and the reference reaction (dissociation of benzoic acids for $\sigma$ constants).

### 1.8.2.2.1 $\quad \sigma$ - Substituent Constants

In certain reactions, developing $\pi$-electron density can be delocalised directly to a parasubstituent that can accept a formal negative charge, such as a nitro or aldehyde group. In these circumstances the reference reaction is not directly comparable (as the charge in the dissociation of benzoic acids cannot be delocalised to para substituents) and so the $\sigma$ constants cannot be expected to provide the basis for a good correlation for the new set of circumstances. As a result, a new modified substituent constant, $\sigma^{-}$, was developed to properly account for such situations. The values of $\sigma^{-}$were obtained from the dissociation constants of substituted phenols in $\mathrm{H}_{2} \mathrm{O}$ at $25{ }^{\circ} \mathrm{C}$, where a negative charge can be delocalised onto particular para substituents, such as a nitro substituent (Scheme 1.26).

b)

Scheme 1.26: a) Dissociation of substituted phenols at $25^{\circ} \mathrm{C}$, reference reaction for $\sigma^{-}$constant; b) example of stabilisation of negative charge onto a $p-\mathrm{NO}_{2}$ group.

Examples of how some Hammett substituent constants change when a negative charge is built up directly adjacent to the aromatic ring can be seen in Table 1.5.

### 1.8.2.2.2 $\sigma^{+}$Substituent Constants

Correspondingly, for reactions where positive charge built up on the reaction centre can be directly stabilised through $\pi$-electron donation by a para substituent, the alternative substituent constant $\sigma^{+}$was developed. Values for $\sigma^{+}$are obtained from rate constants of the solvolyses of substituted cumyl chlorides in $90 \%$ aqueous acetone at $25^{\circ} \mathrm{C}$ (Scheme 1.27).

a)

b)

Scheme 1.27: a) Solvolyses of substituted cumyl chlorides in $90 \%$ aqueous acetone at $25{ }^{\circ} \mathrm{C}$, reference reaction for $\sigma^{+}$constant; b) example of stabilisation of positive charge by $p-\mathrm{NH}_{2}$ group.

Examples of how some Hammett substituent constants change when a positive charge is built up directly adjacent to the aromatic ring can be seen in Table 1.5.

### 1.8.2.2.3 The Yukawa-Tsuno Equation ${ }^{113}$

The Yukawa-Tsuno equation is an extension of the Hammett equation. Rather than selecting either the parameter for no significant resonance conjugation between the reaction site and the substituent ( $\sigma$ ), or the parameter for full conjugation ( $\sigma^{-}$or $\sigma^{+}$), the Hammett equation is refined to acknowledge the possible presence of an intermediate degree of resonance interaction. This degree of resonance is denoted by a new parameter, $r^{-}$or $r^{+}$, depending on whether the substituent is accepting or donating an electron pair, respectively. For electron pair acceptors, adding the extra term gives eqn (1.19).

$$
\begin{equation*}
\log \left\{\frac{k_{\mathrm{x}}}{k_{0}}\right\}=\rho\left\{\sigma+r^{-}\left(\sigma^{-}-\sigma\right)\right\} \tag{1.19}
\end{equation*}
$$

Analogously, for electron pair donors eqn (1.20) is used.

$$
\begin{equation*}
\log \left\{\frac{k_{\mathrm{X}}}{k_{0}}\right\}=\rho\left\{\sigma+r^{+}\left(\sigma-\sigma^{+}\right)\right\} \tag{1.20}
\end{equation*}
$$

$r^{-}$and $r^{+}$values can be determined by initially determining the $\rho$ value using only metasubstituted compounds or para-substituted compounds where $\sigma=\sigma^{-}$or $\sigma=\sigma^{+}$. The value of $r^{-}$ or $r^{-}$can then be found from the gradient of a plot of $\left(\frac{1}{\rho} \cdot \log \left\{\frac{k_{\mathrm{X}}}{k_{\mathrm{H}}}\right\}-\sigma\right)$ against the difference of $\sigma$ and $\sigma^{-} / \sigma^{+}$.

Other extensions of the Hammett equation that will not be discussed include the Taft equation, ${ }^{114}$ which introduces steric influences and the Swain-Lupton equation, ${ }^{115}$ which divides the substituent constant into field (inductive) and resonance effects.

### 1.8.2.3 Cross-Interaction Terms ${ }^{116,117}$

The incorporation of more than one substituted aromatic ring in a reactant can increase the number of terms required in the Hammett equation. For example, Lee et al. ${ }^{118}$ studied the nucleophilic substitution of substituted benzoyl chlorides with substituted anilines (Scheme 1.28).

Scheme 1.28: Nucleophilic substitution of substituted benzoyl chlorides with substituted anilines, in methanol at $35^{\circ} \mathrm{C}$.

Variation of either X- or Y- substituent over the full range of substituents in Scheme 1.28 gives a table of 12 rate constants. A value of $\rho$ can be determined from the data in each line and column of the table. One series of $\rho$ will be for variation of the nucleophile with different electrophilic centres and the other series of $\rho$ will be for variation of the electrophilic centre with different nucleophiles. Rather than reporting a range of $\rho_{\mathrm{X}}$ and $\rho_{\mathrm{Y}}$ values, however, the kinetic data can be summarised in terms of eqn (1.21).

$$
\begin{equation*}
\log \left\{\frac{k_{\mathrm{XY}}}{k_{\mathrm{HH}}}\right\}=\rho_{\mathrm{X}} \sigma_{\mathrm{X}}+\rho_{\mathrm{Y}} \sigma_{\mathrm{Y}}+\rho_{\mathrm{XY}} \sigma_{\mathrm{X}} \sigma_{\mathrm{Y}} \tag{1.21}
\end{equation*}
$$

where $\rho_{\mathrm{X}}$ and $\rho_{\mathrm{Y}}$ are the reaction constants for varying the X - and Y -substituent respectively, $\sigma_{\mathrm{X}}$ and $\sigma_{\mathrm{Y}}$ are the substituent constants for the X - and Y -substituent respectively and $\rho_{\mathrm{XY}}$ is the cross-interaction term.
$\rho_{\mathrm{XY}}$ is usually obtained by multiple-regression analysis. The cross-interaction term affords information as to the intensity of the interaction between the two substituents through the reaction system framework. In the example shown in Scheme 1.28, $\rho_{\mathrm{XY}}=-0.68$. The negative sign of $\rho_{\mathrm{XY}}$ suggests that a stronger nucleophile (more electron-donating X-substituent) gives a more positive reaction constant when varying the electrophile, resulting from a greater degree of bond-formation in the transition state (i.e. the development of more negative charge on reaction centre).

Other systems have been analysed where three aromatic rings have been included in the reaction centres, ${ }^{119,120}$ but that is beyond the scope of this thesis.

### 1.8.2.4 Application of the Hammett Equation to Heterocycle-Substituted Reactants

It was first suggested that effective substituent constants could be defined for aromatic heterocycles by Jaffé. ${ }^{108}$ Since then a range of substituent constants have been proposed for many different heterocycles. Agreement on specific values has proved difficult - Charton ${ }^{121}$ lists eight different values of reported $\sigma$ values for 2-thienyl substitution, ranging from -0.15 to 0.71 , determined by correlation with various reference reactions. As the author notes, in order to be useful, substituent constants should be reasonably constant for a range of reactions. As such, the scope for inclusion of heteroaryl groups within the Hammett equation appears limited, and efforts to do so must be viewed in this context. For five-membered heterocycles, the substituent constants used in this thesis were determined by correlation with the $\mathrm{p} K_{\mathrm{a}}$ of benzoic acids in water at $25^{\circ} \mathrm{C} .{ }^{122,123}$ As they are the second most frequently found aromatic heterocycle in drug databases (after benzene), ${ }^{124}$ it is also desirable to obtain $\sigma$ values for pyridine-substituted compounds. Determining $\sigma$ values for pyridines is complicated by protonation on the heteroatom, which can also lead to zwitterion formation and tautomerisation when determining $\sigma$ values from data for nicotinic and isonicotinic acids (which are analogous to benzoic acids). ${ }^{125}$ Protonation also makes the pyridine heterocycle much more electron-withdrawing and hence different $\sigma$ values exist for neutral and protonated pyridine as substituent. The substituent constants used for heterocycles in this thesis are summarised in Table 1.8.

Table 1.8: Hammett $\sigma$ values of heterocycles determined by correlation with $\mathrm{p} K_{\mathrm{a}}$ of benzoic acids in water at $25{ }^{\circ} \mathrm{C} .{ }^{122,} 123$ Pyridine $\sigma$ values determined at $22{ }^{\circ} \mathrm{C} .{ }^{125}$

| Heterocycle | Heteroatom position |  |
| :---: | :---: | :---: |
|  | $\alpha$ | $\beta$ |
| thiophene | 0.72 | 0.12 |
| furan | 1.08 | 0.25 |
| pyrrole | -0.24 | -0.34 |
|  | 3 | 4 |
| pyridine | 0.45 | 0.76 |
| protonated pyridine | 2.09 | 2.34 |

The $\sigma$ values for pyridines in Table 1.8 are supported by $\mathrm{p} K_{\mathrm{a}}$ data for substituted phenyl ketones reported by Richard et al. ${ }^{126}$ (Scheme 1.29).

14.8

12.7

7.0

Scheme 1.29: Comparison of $\mathrm{p} K_{\mathrm{a}}{ }^{\prime}$ 's for substituted phenyl ketones.
Scheme 1.29 shows a decrease of two $\mathrm{p} K_{\mathrm{a}}$ units for a carbon acid when an adjacent phenyl group is substituted for a 4-pyridyl group, and a decrease of nearly $8 \mathrm{p} K_{\mathrm{a}}$ units for a carbon acid when an adjacent phenyl group is substituted for a protonated 4-pyridyl group. These figures are consistent with the $\sigma$ values for pyridine substituents displayed in Table 1.8, which suggest that a 4-pyridyl group is more electron-withdrawing than a phenyl group and that a protonated 4-pyridyl group is far more electron-withdrawing than a phenyl group.

### 1.9 Thermodynamic Activation Parameters

### 1.9.1 The Arrhenius Equation

The Arrhenius equation describes the temperature dependence of reaction rate constants. In terms of the Arrhenius equation, each reaction has a pre-exponential factor, $A$, and an activation energy, $E_{\mathrm{a}}$, both of which have negligible temperature dependence over small temperature ranges. The Arrhenius equation takes the form of eqn (1.22). ${ }^{127}$

$$
\begin{equation*}
k=A \cdot \mathrm{e}^{-E_{\mathrm{a}} / R T} \tag{1.22}
\end{equation*}
$$

where $k$ is the rate constant, $A$ is the pre-exponential factor (having the same units as $k$ ), $E_{\mathrm{a}}$ is the activation energy, $R$ is the gas constant and $T$ the temperature.

Collision theory suggests that the pre-exponential factor is the constant of proportionality between the concentration of reactants and the rate at which the reactant molecules collide in the correct orientation for reaction. The activation energy is the minimum kinetic energy required for a particular collision to result in reaction, and reflects the temperature dependence of the rate constant. ${ }^{128}$ The greater the activation energy, the greater the temperature dependence of the reaction in question.

Eqn (1.22) can alternatively be written as eqn (1.23).

$$
\begin{equation*}
\ln k=\ln A-\frac{E_{a}}{R T} \tag{1.23}
\end{equation*}
$$

Eqn (1.23) shows that a plot of $\ln k$ against $1 / T$ should result in a linear graph, with a $y$-axis intercept equal to $\ln A$ and a gradient of $-E_{\mathrm{a}} / R$. This plot is known as an Arrhenius plot.

### 1.9.2 The Eyring Equation

The Eyring equation also describes the change in rate constant as a function of temperature. The Eyring equation differs from the Arrhenius equation in that it is based on the standard molar Gibbs energy of activation, $\Delta G^{\ominus \ddagger}$, of a reaction. The Eyring equation can be used to determine the enthalpy and entropy of activation for a chemical reaction. The general form of the equation is given by eqn (1.24). ${ }^{129-131}$

$$
\begin{equation*}
k=\left(\frac{k_{\mathrm{B}} T}{h}\right) \cdot \mathrm{e}^{-\frac{\Delta G:}{R T}} \tag{1.24}
\end{equation*}
$$

where $k_{\mathrm{B}}$ is the Boltzmann constant, $h$ is Planck's constant and $\Delta G^{\ddagger}$ is the Gibbs energy of activation.

Inserting the terms for enthalpy and entropy of activation into eqn (1.24) gives eqn (1.25)

$$
\begin{equation*}
k=\left(\frac{k_{\mathrm{B}} T}{h}\right) \cdot \mathrm{e}^{-\frac{\Delta H^{\ddagger}}{R T}} \cdot \mathrm{e}^{\frac{\Delta S^{\ddagger}}{R}} \tag{1.25}
\end{equation*}
$$

Eqn (1.25) can be rearranged to the linear form, eqn (1.26).

$$
\begin{equation*}
\ln \left(\frac{k}{T}\right)=\left(\frac{-\Delta H^{\ddagger}}{R T}\right)+\ln \left(\frac{k_{\mathrm{B}}}{h}\right)+\left(\frac{\Delta S^{\ddagger}}{R}\right) \tag{1.26}
\end{equation*}
$$

where $\Delta H^{\ddagger}$ is the enthalpy of activation and $\Delta S^{\ddagger}$ is the entropy of activation
Eqn (1.26) shows that a plot of $\ln k / T$ against $1 / T$ should result in a linear plot (Eyring plot). The gradient of this plot equals $-\Delta H^{\ddagger} / R$, and the $y$-axis intercept equals $\ln \left(k_{\mathrm{B}} / h\right)+\Delta S^{\ddagger} / R$.

### 1.9.3 Interpretation of Eyring Thermodynamic Activation Parameters

Interpretation of $\Delta H^{\ddagger}$ and $\Delta S^{\ddagger}$ values is best done by comparison. Table 1.9 shows a selection of typical literature values of $\Delta H^{\ddagger}$ and $\Delta S^{\ddagger}$.

Table 1.9: Some examples of activation parameters.

| Reaction | $\Delta H^{\ddagger} / \mathrm{kJ} \mathrm{mol}^{-1}$ | $\Delta S^{\ddagger} / \mathrm{J} \mathrm{K}^{-1} \mathrm{~mol}^{-1}$ |
| :---: | :---: | :---: |
| Hydrolysis of $\mathrm{CH}_{3} \mathrm{Cl}^{132,133}$ | 100.4 | -51.5 |
| Hydrolysis of $\mathrm{CH}_{3} \mathrm{Br}{ }^{132,133}$ | 96.2 | -42.3 |
| Hydrolysis of $\mathrm{CH}_{3} \mathrm{I}^{132,133}$ | 102.7 | -33.9 |
| Hydrolysis of $\mathrm{n}-\mathrm{C}_{3} \mathrm{H}_{7} \mathrm{Br}{ }^{132,133}$ | 92.5 | -56.9 |
| Solvolysis of $t$-Butyl chloride $\text { in } \mathrm{H}_{2} \mathrm{O}{ }^{132,134}$ | 97.15 | 51.0 |
| Solvolysis of $t$-Butyl chloride $\text { in } \mathrm{CH}_{3} \mathrm{OH}$ <br> 132, 134 | 104.1 | -13.0 |
| Solvolysis of $\mathbf{1 . 1 9}$ in $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}{ }^{132,134}$ | 124.0 | -9.2 |
| Solvolysis of $\mathbf{1 . 1 9}$ in $\mathrm{HCO}_{2} \mathrm{H}^{132,134}$ | 104.0 | 15.0 |
| Solvolysis of $\mathbf{1 . 2 0}$ in $\mathrm{H}_{2} \mathrm{O}{ }^{135}$ | 43.0 | -179.0 |
| Thermal decomposition of 1,1 '-azobutane ${ }^{136,137}$ | 217.6 | 79.5 |
| Dimerisation of cyclopentadiene ${ }^{137,138}$ | 64.9 | -142.3 |

1.19

1.20
$\Delta H^{+}$corresponds to the energy required for bond reorganisation in formation of the activated complex. ${ }^{137}$ The energy cost of breaking a bond means that $\Delta H^{\dagger}$ will be high if bond breaking is important in the rate-determining step, and low if bond formation is important in the ratedetermining step. An example of a large $\Delta H^{\dagger}$ is the thermal decomposition of $1,1^{\prime}$-azobutane, where the rate-determining step is homolytic breaking of C-N bonds. A large $\Delta H^{\ddagger}$ is found because there is little bond formation to compensate for the bond breaking. The solvolysis of 1.20, and the dimerisation of cyclopentadiene have low $\Delta H^{\ddagger}$ as both reactions involve concerted cyclisation mechanisms with bond formation simultaneous with bond breaking.
$\Delta S^{\dagger}$ corresponds to the degree of organisation that results from activated complex formation. Loss of degrees of electronic, rotational or translation freedom in forming the activated complex results in reduced entropy of the system and hence $\Delta S^{\ddagger}$ will be strongly negative. A gain of degrees of electronic, rotational or translation freedom through molecules falling apart will result in $\Delta S^{\ddagger}$ being slightly negative or positive. The values in Table 1.9 for $\Delta S^{\ddagger}$ reflect this. The hydrolysis reactions occurring by an $\mathrm{S}_{\mathrm{N}} 2$ mechanism have a negative $\Delta S^{\ddagger}$ as bringing together the molecules for reaction reduces the entropy. The solvolysis reactions of $t$ butyl chloride and $\mathbf{1 . 1 9}$ have only slightly negative or positive $\Delta S^{\ddagger}$ as the molecule 'falls apart' increasing disorder in the $\mathrm{S}_{\mathrm{N}} 1$ mechanism. Slightly negative $\Delta S^{\ddagger}$ in the solvolysis of $t$ butyl chloride and $\mathbf{1 . 1 9}$ are due to solvent rearrangement giving an increasingly structured solvation of the ionic intermediates. The large positive value of $\Delta S^{\ddagger}$ for thermal decomposition of 1,1 '-azobutane is due to the increased entropy resulting from transformation of one molecule to three. Conversely, formation of highly ordered cyclic transition states results in the strongly negative $\Delta S^{\ddagger}$ for solvolysis of $\mathbf{1 . 2 0}$, and dimerisation of cyclopentadiene.

### 1.10 Experimental Techniques

### 1.10.1 ${ }^{1}$ H NMR Spectroscopy ${ }^{139-142}$

The technique Nuclear Magnetic Resonance (NMR) spectroscopy relies on protons and neutrons having a property called 'spin'. When placed in a magnetic field, spin will cause protons and neutrons to orientate themselves either with the magnetic field or opposed to it. The small energy gap between these two states is dependent on the interaction between the nucleus and the magnetic field. Application of electromagnetic radiation of a specific frequency will cause the nuclei to switch from the low energy state (aligned with the magnetic field) to the high energy state (against the magnetic field). Each spin-active nucleus has a different resonance frequency and can therefore be distinguished. Furthermore, this resonance frequency is also slightly dependent on the chemical environment in which the nucleus finds itself. This difference in resonance frequency allows distinction between atoms in different chemical environments and allows for elucidation of a molecular structure.

As discussed previously (Section 1.3), proton-deuterium exchange can be used to indirectly investigate the rate constant and mechanism of racemisation. ${ }^{1} \mathrm{H}$ NMR spectroscopy as a method of determining the rate of $\mathrm{H} / \mathrm{D}$ exchange has been frequently used to investigate the
racemisation of stereogenic centres of type $\mathrm{R}^{\prime \prime}$ ' ${ }^{\prime} \mathrm{RC}-\mathrm{H}^{33}{ }^{33,39,57,59,143-145}$ The molecule under investigation is dissolved in a $\mathrm{D}_{2} \mathrm{O}$-based buffer and incubated at the desired temperature. ${ }^{1} \mathrm{H}$ NMR spectra of the compound are recorded over a period of time. If the protons bound to the stereogenic centre of the molecule exchange with solvent, they will be replaced by deuterons. As a result, the ${ }^{1} \mathrm{H}$ NMR spectra will show a decrease in the intensity of the peak corresponding to the proton bound to the stereogenic centre. This decrease in intensity can be recorded in relation to peaks in the ${ }^{1} \mathrm{H}$ NMR spectrum from another part of the molecule (that is assumed not to undergo $\mathrm{H} / \mathrm{D}$ exchange itself), ${ }^{146}$ or relative to an external standard added to the solution.

### 1.10.2 Mass Spectrometry ${ }^{147}$

Mass Spectrometry (MS) is an important tool in compound characterisation. The procedure to obtain a mass spectrum can be divided into three stages: initial vaporisation of the analyte; production of ions from the gas-phase molecules formed; and subsequent separation and detection of these ions by their mass-to-charge ratio ( $\mathrm{m} / \mathrm{z}$ ). Vaporisation is achieved by heating a sample to high temperatures at low pressure. Ionisation is usually achieved through either the electron impact (EI) or chemical ionisation (CI) method. EI proceeds by firing an electron beam at the sample, removing an electron from the sample and leaving a radicalcation (eqn 1.27).

$$
\begin{equation*}
\mathrm{M}+e \rightarrow \mathrm{M}^{\bullet+}+2 e \tag{1.27}
\end{equation*}
$$

The molecular ions produced through EI can then fragment through well documented fragmentation processes. The pattern of fragment ions can then be used to characterise the compound.

CI proceeds by collision of the sample with ions of a reagent gas to give a protonated sample. Initial ionisation of a sample gas such as methane is done with an electron beam as in EI producing a radical cation (eqn 1.28).

$$
\begin{equation*}
\mathrm{CH}_{4}+e \rightarrow \mathrm{CH}_{4}^{\bullet+}+2 e \tag{1.28}
\end{equation*}
$$

The radical cation produced will then collide with neutral molecules to yield a cation (eqn 1.29).

$$
\begin{equation*}
\mathrm{CH}_{4}^{\bullet+}+\mathrm{CH}_{4} \rightarrow \mathrm{CH}_{5}^{+}+\mathrm{CH}_{3}^{\bullet} \tag{1.29}
\end{equation*}
$$

Entering the sample into this mixture will cause $\mathrm{CH}_{5}{ }^{+}$to act as a strong acid and the sample is protonated (eqn 1.30).

$$
\begin{equation*}
\mathrm{M}+\mathrm{CH}_{5}^{+} \rightarrow \mathrm{MH}^{+}+\mathrm{CH}_{4} \tag{1.30}
\end{equation*}
$$

Fragmentation is less common in CI than EI. This makes the molecular weight of the sample easily obtainable, as the observed $m / z$ value will be one unit larger than the sample's molecular weight. Detection of the ions from both ionisation methods is achieved using a mass analyser. The mass analyser separates the ions from the spectrometer by deflection of the ions in a strong magnetic field; ions of greater mass are deflected less than those of a smaller mass. Mass spectrometry can also be enhanced by coupling the technique to gas and liquid chromatographs (GCMS and LCMS). This allows for chemical separation of analytes before characterisation by MS.

As in the case of ${ }^{1} \mathrm{H}$ NMR spectroscopy, MS has been used to investigate the rate constant and mechanism of racemisation by determining the rate of $\mathrm{H} / \mathrm{D}$ exchange. ${ }^{143}$ Monitoring the reaction over time and determining the ratio of the parent compound ion to its deuterated equivalent from the CI spectra, allows calculation of the rate constant of deuterium incorporation at the stereogenic centre.

### 1.10.3 Circular Dichroism ${ }^{148}$

Circular Dichroism (CD) is a phenomenon arising from the molecular property of chirality. The technique of $C D$ spectroscopy works through analysis of the sample using plane polarised light. Plane-polarised light consists of two components of circularly polarised light of equal intensity but rotating in opposite directions. These are known as right circularly polarised light (rcpl) and left circularly polarised light (lcpl). Rcpl and lcpl are mirror images of each other. Each component will interact differently with an enantiomer of a chiral molecule.

The absorbance of unpolarised light by a sample is defined in eqn (1.31).

$$
\begin{equation*}
A=\log \left(I_{0} / I\right) \tag{1.31}
\end{equation*}
$$

where $A$ is the absorbance of unpolarised light, $I$ is the intensity of light after it has travelled a distance $l$ through the sample, $I_{0}$ is the intensity before it has travelled through sample $A$ can also be described by the Beer-Lambert law, eqn (1.32).

$$
\begin{equation*}
A=\varepsilon \cdot C \cdot l \tag{1.32}
\end{equation*}
$$

where $\varepsilon$ is the molar absorption coefficient $\left(\mathrm{M}^{-1} \mathrm{~cm}^{-1}\right), C$ is the molar concentration (M), $l$ is the sample pathlength ( cm )

Similarly, molar absorption coefficients can be defined for rcpl and lcpl. This allows us to calculate the molar circular dichroism (eqn 1.33)

$$
\begin{equation*}
\Delta \varepsilon=\varepsilon_{\mathrm{L}}-\varepsilon_{\mathrm{R}}=\left(A_{\mathrm{L}}-A_{\mathrm{R}}\right) / C l \tag{1.33}
\end{equation*}
$$

where $\Delta \varepsilon$ is the molar circular dichroism $\left(\mathrm{M}^{-1} \mathrm{~cm}^{-1}\right), \varepsilon_{\mathrm{L}}$ is the molar absorption coefficient of left hand polarised light $\left(\mathrm{M}^{-1} \mathrm{~cm}^{-1}\right), \varepsilon_{\mathrm{R}}$ is the molar absorption coefficient of right hand polarised light $\left(\mathrm{M}^{-1} \mathrm{~cm}^{-1}\right), A_{\mathrm{L}}$ is the absorbance of left hand polarised light, $A_{\mathrm{R}}$ is the absorbance of right hand polarised light

The CD instrument measures the intensity of rclp and lclp after passing through the sample and from the intensities determines $A_{\mathrm{L}}-A_{\mathrm{R}}$ and then $\Delta \varepsilon$ using the equations above.

CD spectroscopy can be used to determine how enantiomerically pure a compound is. Several examples exist of its use as a method of determining loss of enantiomeric excess and hence rate constants of racemisation. ${ }^{149,150}$

### 1.10.4 Computational Chemistry

The use of computers to rapidly perform high-level theoretical chemistry calculations has become widespread. Molecular information such as the most stable configuration of nuclei and the relative energy of such configurations can be theoretically obtained through such calculations.

Calculations in Chapter 5 were performed using Density Functional Theory (DFT). ${ }^{151}$ DFT uses approximations of electron interactions to convert the wavefunction into electron density. Differing approximations give rise to different functionals. The functional used in this body of work is RB3LYP. ${ }^{152}$

Also important in computational chemistry is the choice of basis set. ${ }^{153}$ The basis set is the set of functions used to model the molecular orbitals. Using a finite basis, only the molecular orbital components along the coordinate axes corresponding to the selected basis are represented. A smaller basis set results in a less computationally expensive calculation, but gives a poorer representation of the molecule. Thus, when choosing a basis set a compromise has to be made between computation time and accuracy. The basis set $6-31+\mathrm{G}(\mathrm{d}, \mathrm{p})$ used in
this body of work is frequently used in computational chemistry as it provides a good balance between computation time and accuracy.

Chemistry is usually carried out in a solution, and the interactions between the solvent and solute can greatly affect molecular properties such as molecular geometry or energy. As a result, the effects of solvation are often incorporated into theoretical calculations to provide a better description of the system under analysis. One approach is to include individual solvent molecules in the calculation, and consider changes in the substrate and solvent due to interactions with one another. However, in order to accurately model these interactions hundreds or thousands of solvent molecules need to be included in the calculations, making such an approach very computationally demanding. Therefore an alternative approach based on continuum models has been developed. ${ }^{154}$

In this body of work, the Polarisable Continuum Model (PCM) of Tomasi et al. ${ }^{155}$ has been used. In the PCM model, a cavity for the molecule is generated based on the van der Waals radii of the atoms in the molecule. A solvent-accessible surface is then manifested by a spherical particle rolling on the surface of the van der Waals surface. This surface is then treated as one continuous dielectric field, and specific solvent-solute interactions are disregarded. This approach provides a relatively cheap computational way of mimicking the effect of a solvent.

### 1.11 Project Goals

We aim to test the existing kinetic data and substituent effect information on racemisation of stereogenic centres of type $\mathrm{R}^{\prime} \mathrm{R}^{\prime} \mathrm{RC}-\mathrm{H}$, and to expand the range of structures for which kinetic data is available. In doing so we aim to:

1. Determine the structures at risk of racemisation

Dependence of racemisation on the types of functional groups adjacent to the stereogenic centre will be tested. The assignments made by Testa et al. (Table 1.1) will be considered and may be further refined.
2. Quantify the risk

Quantification of the rate constants of racemisation will allow direct comparison of the risk of racemisation for different structures. By modifying the structures this may allow us to quantify the effect of each particular functional group on racemisation.
3. Establish conditions where racemisation is a threat

By investigating the dependence of racemisation rate constants on pH , temperature and general-acid or -base concentration, we will be able to determine which factors are important for racemisation of individual structures and functional groups.
4. Investigate mechanisms of racemisation

Examination of the mechanism (or mechanisms) by which a molecule undergoes racemisation is an important goal of the project. This aspect of the project runs parallel to the dependence on structural aspects on the molecule. The variation with structure of rate constants for racemisation will allow insight into the mechanism by which racemisation takes place.
5. Explore possible methods for prediction of structures at risk of racemisation

The ability to assess whether a particular molecule is configurationally unstable under pharmacological conditions without having to undertake experimentation would be beneficial. The ability to predict configurational stability depends on knowledge of the mechanisms by which configurational instability occurs, and will allow structural features to be related to rate constants for racemisation. The use of computational chemistry to predict structures at risk will also be investigated.

## 2 Database Mining

### 2.1 Introduction

Our interest in racemisation is primarily from a pharmaceutical perspective. It is therefore important to have some perspective on the types of compounds, and more specifically the types of stereogenic centres commonly found in pharmacologically-active compounds. As a result, a body of data regarding different functional groups that are found adjacent to a stereogenic centre in compounds of interest was obtained and analysed. Of specific interest is to gather information on which functional groups appear, the frequency at which they are seen, and the combinations in which they are found. Such information on functional groups will also make it possible to classify combinations of functional groups as 'at risk' of racemisation (either through base or acid catalysis) and to see the frequency at which such combinations occur.

AstraZeneca possess large databases of compounds of different origin. Here, two databases were examined; the ISAC database, containing details of all compounds registered as of interest by AstraZeneca over the history of the company and its predecessors; and the IBEX database, an externally managed database, comprising of any compounds that appear in the medicinal chemistry literature. Both databases are very large; ISAC contains over 1 million compounds and IBEX over half a million. The trends found in such large libraries of molecules provide insight into which types of stereogenic centre have been most frequently investigated as potential drugs and how often these stereogenic centres appear to be configurationally unstable.*

The information in the IBEX and ISAC databases is recorded using the SMILES ${ }^{1-8}$ (Simplified Molecular Input Line Entry Syntax) chemical language. SMILES syntax enables molecules and reactions to be represented using a series of ASCII characters. The basic structure of the language is outlined in the appendix (Section 2.6.1.1).

An important tool in cheminformatics is sub-structure targeting of compounds in molecular databases to find a desired chemical 'motif'. The SMARTS', ${ }^{10}$ (Smiles Arbitrary Target Specification) chemical language is an extension of SMILES that enables searching for specific patterns within molecules and was used for that purpose in this chapter. A brief overview of SMARTS can be found in the experimental (Section 2.6.1.2). SMARTS have been used in studies filtering out molecules with detrimental ADMET ${ }^{\dagger}$ properties, ${ }^{11,12}$

[^4]assessing risk of undesired reactivity between compounds in pooled screening studies, ${ }^{13}$ identifying commonly occurring molecular fragments found in on-the-market drugs ${ }^{14}$ and quantifying the effects of structural changes on pharmaceutical properties. ${ }^{15}$

### 2.2 Analysis

### 2.2.1 'Chiral Chopper'

In order to separately classify each substituent bound to a stereogenic centre in each molecule listed in the databases, it was first necessary to identify each stereogenic centre and separate the substituents around it. This was achieved using a program developed in-house by AstraZeneca named 'Chiral Chopper'. The program analyses a database of SMILES strings and detects any stereogenic centres within chiral molecules in the database. The program then performs an operation on the molecule which outputs a SMILES string representing the molecule divided around the stereogenic centre, with the stereogenic centre replaced by a Xenon atom. An example of the operation of the 'Chiral Chopper' program on a simple molecule is displayed in Scheme 2.1.

Scheme 2.1: Illustration of operation of 'Chiral Chopper' program on 2 -aminobutanoic acid.

The Xenon atom is inserted as a marker for the stereogenic centre, as it allows for recognition through SMARTS queries. It is now possible to define various types of substituent and analyse each newly divided molecule to see which substituents are present on the various stereogenic centres.

### 2.2.2 Classification of Substituents

In order to analyse the substituents on each stereogenic centre in the databases it is necessary to choose how substituents are to be defined and how specific each definition is to be. For
example, it might be sufficient to define a substituent simply as an amide but primary and secondary amides could also be defined differently. The orientation of certain functional groups with respect to the stereogenic centre may also impact whether the group facilitates racemisation or not.

The categories of amides and amines were divided into primary, secondary and tertiary. This is because different substitution patterns can be expected to have different inductive effects. Also important is the nature of the substituents. Some amides and amines were classified as acidic or nonacidic. Amide substituents with a labile proton (Scheme 2.2) will affect an adjacent stereocentre differently from those where the proton is constantly bound.

Scheme 2.2: Illustration of acidic secondary amide substituent classification.
If the aromatic group in Scheme 2.2 was to be replaced by an alkyl group the acidic nature of the amide proton would not be retained. The difference in inductive effects of differently substituted amides is illustrated by their $\sigma_{\mathrm{I}}$ values (Scheme 2.3), quantifying the electronwithdrawing nature of the substituent.

$\sigma_{\mathrm{I}}=$
0.26

0.35

0.17

Scheme 2.3: Inductive effect constants for three different amides. ${ }^{16}$
Amide substituents which did not fall into either the aromatic ('acidic') or alkyl ('nonacidic') were classified in a separate category (amide 'other'). Tertiary amides and amines were similarly divided into separate categories dependent on the nature of the groups bound to the nitrogen atom.

Amine groups were defined in the same manner as amides. Although the proton on a secondary amine cannot be said to be 'acidic' in the same manner as for an amine, the same terminology has been used. In this instance, the term 'acidic' refers to the conjugate acid of the secondary amine, which will be more acidic if the amine is aromatic substituted rather than alkyl substituted.

The orientation of an amide with respect to the stereogenic centre is also of interest. Stabilisation of a carbanion by an amide can occur in a different manner dependent on the orientation of the amide. If the carbonyl is adjacent, stabilisation occurs through delocalisation of charge onto the oxygen. If the nitrogen is adjacent, stabilisation occurs through electrostatic interactions between the carbanion and the partial positive charge on the nitrogen (Section 1.4). Amides bound to the stereogenic centre through nitrogen were therefore categorised separately as 'reverse amides', and were also separated into secondary and tertiary classifications.

Because we are essentially interested in the effects on the stability of a carbanion, aromatic groups also require subdivision into more specific categories. Initially, categories were created for five- and six-membered aromatics, with three-, four- and seven-membered groups categorised in 'other'. However, it became apparent that most of the aromatic groups fell in the six-membered category. As a result it was decided to split this group into different types of aromatic, with benzene and various nitrogen-containing heterocycles classified separately.

The SMARTS output for each stereogenic centre consists of a series of numbers each corresponding to a different category. The number denotes how many of the substituents on the stereogenic centre are classified in that category. For example, 2-aminobutanoic acid (Scheme 2.1) will return a ' 1 ' in the categories of proton, alkyl, primary amine and carboxylic acid. Every other category will return ' 0 '. In order to check that most substituents are recognised, the sum of the substituents was calculated and any molecules not adding up to 4 were scrutinised. If necessary the SMARTS query was then modified to be more specific and run again.

After this iterative process was complete, a total of 52 different categories for substituents were established. These are listed in Table 2.1. For details on how each was coded, see the experimental (Section 2.5.1). Many of these substituents are fairly common, such as protons, alkyls and halogens. Other less commonly found groups include epoxides, ammonium salts and thioethers. Numerous very rare groups such as thiols, azides and sulfiniums were grouped together as 'other'.

Table 2.1: Substituent categories defined in SMARTS query.

|  |  | Amides | Amines | Aromatics |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Proton | Carboxylic acid | Primary | Primary | Benzene | Hydroxylamine |
| Halogen | Ketone | Secondary with non-acidic proton | Secondary with non-acidic proton | Ortho pyridine | Hydroxamic acid |
| Hydroxyl | Ester | Secondary with acidic proton | Secondary with acidic proton | Meta pyridine | Thioether |
| Alkyl | 'Reverse' Ester | Other secondary | Other secondary | Para pyridine | Imide |
| Alkene | Ether | Tertiary with two alkyl groups | Tertiary with two alkyl groups | 2,4-pyrimidine | Imine |
| Alkyne | Aromatic ether | Tertiary with two aromatic groups | Tertiary with two aromatic groups | 2,6-pyrimidine | 'Reverse' imine |
| Nitrile | Ether and double bond | Tertiary with one aromatic, one alkyl group | Tertiary with one aromatic, one alkyl group | 3,5-pyrimidine | Quaternary ammonium |
| Nitro | Epoxide | Other tertiary | Other tertiary | 2,3-pyradizine | Sulfoxide |
|  |  | 'Reverse' secondary |  | 3,4-pyradizine | Sulfilimine |
|  |  | 'Reverse' tertiary |  | Pyrazine | Isonitrile |
|  |  | Double bonded amide |  | Triazine | Thiocarbonyl |
|  |  |  |  | Other six membered aromatic | Other |

### 2.3 Results and Discussion

The sheer number of stereogenic centres analysed in this work (over 1 million in the ISAC database alone) means that there are likely to be a few examples of any type of stereogenic centre that can be formed by combining the substituent categories listed in Table 2.1. Because of this, the focus of our analysis has been on the 250 most frequently occurring combinations of substituents.

### 2.3.1 Overview of Most Frequently Occurring Combinations of Substituents

The most frequently occurring combinations of substituents around stereogenic centres in the ISAC database are displayed in Table 2.2.

Table 2.2: Details of 20 most common combinations of substituents on stereogenic centres found in the ISAC database.

| Combination of substituents on stereocentre | No. <br> stereocentres |  |
| :--- | :--- | :--- |
| $\mathbf{1}$ | 1 proton, 3 alkyl | 134476 |
| $\mathbf{2}$ | 1 proton, 1 hydroxyl, 2 alkyl | 108097 |
| $\mathbf{3}$ | 1 proton, 1 alkyl, 1 nonacidic sec. amide, 1 reverse sec. amide | 85149 |
| $\mathbf{4}$ | 1 proton, 2 alkyl, 1 ether | 73318 |
| $\mathbf{5}$ | 1 proton, 2 alkyl, 1 dialkyl tert. amine | 58810 |
| $\mathbf{6}$ | 1 proton, 2 alkyl, 1 reverse tert. amide | 45324 |
| $\mathbf{7}$ | 1 proton, 2 alkyl, 1 reverse sec. amide | 45034 |
| $\mathbf{8}$ | 1 proton, 2 alkyl, 1 benzene | 36976 |
| $\mathbf{9}$ | 1 proton, 1 alkyl, 1 nonacidic sec. amide, 1 reverse tert. amide | 28017 |
| $\mathbf{1 0}$ | 1 proton, 1 reverse tert. amide, 1 benzene, 1 thioether | 25241 |
| $\mathbf{1 1}$ | 1 proton, 1 alkyl, 1 dialkyl tert. amide, 1 reverse sec. amide | 24437 |
| $\mathbf{1 2}$ | 1 proton, 1 alkyl, 1 benzene, 1 reverse tert. amide | 21560 |
| $\mathbf{1 3}$ | 1 proton, 1 alkyl, 1 benzene, 1 dialkyl tert. amine | 20388 |
| $\mathbf{1 4}$ | 1 proton, 2 alkyl, 1 reverse ester | 20342 |
| $\mathbf{1 5}$ | 1 proton, 2 alkyl, 1 nonacidic sec. amine | 20100 |
| $\mathbf{1 6}$ | 1 proton, 2 alkyl, 1 aromatic ether | 20065 |
| $\mathbf{1 7}$ | 1 proton, 1 alkyl, 1 benzene, 1 reverse sec. amide | 19871 |
| $\mathbf{1 8}$ | 1 proton, 2 alkyl, 1 alkene | 19031 |
| $\mathbf{1 9}$ | 1 proton, 2 alkyl, 1 five membered aromatic | 17887 |
| $\mathbf{2 0}$ | 1 proton, 1 hydroxyl, 1 alkyl, 1 benzene | 16882 |

${ }^{a}$ from a total of $1,607,343$ stereogenic centres

Immediately apparent from Table 2.2, is that all of the top 20 (and 90 of the top 100) most frequently occurring combinations have a proton as one of the substituents. This feature
potentially makes them susceptible to racemisation by proton abstraction by base, as discussed in Section 1.3. As a result it becomes important to assess whether other substituents on these stereogenic centres can stabilise a negative charge, as the ability to do so will make the stereogenic centre more vulnerable to racemisation through the $\mathrm{S}_{\mathrm{E}} 1$ and $\mathrm{S}_{\mathrm{E}} 2$ mechanisms (Section 1.3).

All bar one of the combinations displayed in Table 2.2 have at least one alkyl substituent. Alkyl substituents were defined by Testa et al. ${ }^{17-19}$ (Table 1.1) as being neutral towards stabilising a carbanion. Stereocentres with a neutral substituent are thought to require two other acid-strengthening groups, one strongly so, in order for configurational instability to be of pharmaceutical or pharmacological significance. The strongly acid-strengthening groups designated in Table 1.1 are ester and aryl ketone groups, which none of the combinations in Table 2.2 contain. As a result, by the definitions in Table 1.1, none of the most frequent occurring stereogenic 'motifs' would be anticipated to be configurationally unstable. Similar conclusions can be drawn from the results of the IBEX database, illustrated in the Appendix to the Chapter (Section 2.6). This conclusion is perhaps a reassuring one, although it may also be a self-fulfilling prophecy if compounds thought or found to be unstable have been avoided. It is preferable that all stereocentres in chiral drug molecules retain configuration to avoid the potentially disastrous consequences discussed in Section 1.1. However, although these very frequently occurring combinations do not appear to be at risk, looking further down the lists examples of stereogenic centres which are at risk of configurational instability start to appear.

### 2.3.2 Analysis of Most Frequently Occurring 'At Risk' Combinations of Substituents

The top 250 most frequently occurring combinations from the ISAC database were analysed and classified as either at risk from base-catalysed racemisation, acid-catalysed racemisation, not at risk or unknown. Table 2.3 shows how many combinations of substituents around a stereogenic centre fell into each risk category.

Table 2.3: Number of combinations of substituents in each classification of racemisation risk, from top 250 most frequently occurring combinations from the ISAC database.

| Type of risk |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Not at risk |  | Base-catalysed |  | Acid-catalysed |  |
| 188 | 38 |  | Unknown |  |  |
|  |  |  | 10 | 14 |  |

As seen in several examples in Chapter $1,{ }^{20-22}$ molecules with an alcohol group bound to the stereogenic centre can be susceptible to acid-catalysed racemisation via protonation of the alcohol followed by dehydration then rehydration, as illustrated in Scheme 1.18. Of the top 250 combinations there were 10 which are potentially susceptible to acid catalysed racemisation, corresponding to 30,517 individual stereogenic centres (Appendix Table 2.8). Many more fit the criteria outlined in Table 1.1 which may make them susceptible to basecatalysed racemisation through proton abstraction. Of the top 250 combinations, 38 are classified as susceptible to base-catalysed racemisation ( 78,360 stereogenic centres) and are displayed in Table 2.4 (overleaf). Combinations with one or more substituent with an unknown effect on configurational stability (from Table 1.1 and chemical intuition) such as a thioether substituent, are classified as of 'unknown' risk (appendix Table 2.9).

Table 2.4 illustrates that many molecules investigated as potential drugs contain scaffolds with stereogenic centres that are potentially unstable under physiological conditions. Table 2.4 shows that many of the combinations thought at risk of racemisation through base catalysis contain a carbonyl adjacent to the stereogenic centre. A carbonyl can stabilise a carbanion through delocalisation of charge onto the oxygen and facilitate racemisation, as discussed in Section 1.4.

Also frequently appearing in Table 2.4 are variously-substituted amine and amide groups bonded to the stereogenic centre through nitrogen. Both are designated in Table 1.1 as decreasing configurational stability suggesting that both groups will stabilise an adjacent carbanion. This is due to the formal or partial positive charge on the nitrogen and the stabilising effect this will have on an adjacent carbanion (Section 1.4).

Table 2.4 shows that a combination of an adjacent carbonyl-containing group with an amine or amide bound through nitrogen is found 17 times within the top 250 most common combinations. Within these 17 different combinations, breakdown of the adjacent carbonyl groups shows that 6 are ester groups, 9 are amide groups and 2 are ketones. Of the adjacent nitrogen containing groups, 11 are amides and 7 are amines. These results are summarised in Table 2.5 (page 67).

Table 2.4: Details of all combinations of substituents within the most common 250 in ISAC, considered at risk of base-catalysed racemisation

|  | Combination of substituents on stereocentre, excluding proton | No. stereocentres ${ }^{\text {a }}$ |
| :---: | :---: | :---: |
| 29 | 1 alkyl, 1 ester, 1 reverse sec. amide | 11628 |
| 35 | 1 benzene, 1 nonacidic sec. amide, 1 reverse tert. amide | 8622 |

| 67 | 1 alkyl, 1 ester, 1 dialkyl tert. amine | * | 3419 |
| 138 | 1 alkyl, 1 ester, 1 nonacidic sec. amine | * | 1383 |
| 188 | 1 alkyl, 1 ester, 1 prim. amine | * | 904 |
| 234 | 1 alkyl, 1 ester, 1 sec . amine (other) | * | 603 |
| Amides |  |  |  |
| 35 | 1 benzene, 1 nonacidic sec. amide, 1 reverse tert. amide |  | 8622 |
| 98 | 1 alkyl and aromatic sub. tert. amide, 1 reverse sec. amide, 1 imine |  | 2143 |
| 106 | 1 five membered aromatic, 1 nonacidic sec. amide, 1 reverse tert. amide |  | 1885 |
| 130 | 1 alkyl and aromatic sub. tert. amide, 1 imine, 1 sec amine (other) | * | 1483 |
| 166 | 1 para pyridine, 1 nonacidic sec. amide, 1 reverse tert. amide |  | 1117 |
| 176 | 1 benzene, 1 acidic sec. amide, 1 reverse tert. amide |  | 1040 |
|  | 1 benzene, 1 alkyl and aromatic sub. tert. amide, 1 reverse tert. amide |  | 899 |
|  | 1 benzene, 1 nonacidic sec. amide, 1 reverse sec. amide |  | 897 |
|  | 1 benzene, 1 acidic sec. amide, 1 reverse sec. amide |  | 627 |
| Ketones |  |  |  |
| 70 | 1 alkyl, 1 ketone, 1 reverse sec. amide |  | 3387 |
| 244 | 1 alkyl, 1 ketone, 1 dialkyl tert. amine | * | 561 |

Also noticeable is the frequent occurrence of aromatic groups in combinations that appear configurationally unstable. Of the 38 combinations that appear in Table 2.4, 22 contain at least one aromatic group substituent. Of these, 17 contain a benzene substituent. Heterocycles are a less common occurrence, with only three pyridine derivatives seen. This observation is consistent with that made by Ghose et al. ${ }^{23}$ In an extensive study of drug databases classifying functional groups found anywhere in drug molecules, they observed that benzene was the most frequently found aromatic group, outnumbering all other heterocycles (aromatics and non-aromatics) combined. The observation of pyridines as the most frequently seen aromatic
group after benzene is consistent with the observations of Lameijer et al. ${ }^{24}$ in their analysis of the database of the National Cancer Institute.

Analysis of the data from the IBEX database was carried out in the same manner as for the ISAC database. As in the ISAC database, none of the 20 most frequently occurring combinations of substituents on a stereogenic centre in the IBEX appear susceptible to basecatalysed racemisation (Table 2.10). Risk-of-racemisation assessment of the top 250 most frequently occurring combinations are shown in Table 2.6.

Table 2.6: Number of combinations of substituents in each classification of racemisation risk, from top 250 most frequently occurring combinations from the IBEX database.

|  | Type of risk |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Not at risk |  | Base-catalysed |  | Acid-catalysed |  |
| 193 | 22 |  | Unknown |  |  |
|  |  |  | 16 | 19 |  |

Although the number of combinations deemed not at risk in Table 2.6 is approximately the same as for the ISAC database, the number deemed at risk of base-catalysed racemisation is much lower and the numbers in the other two risk categories slightly higher. The manner in which the two databases are compiled suggests potential explanations for this difference. The ISAC database is comprised of any compound that has ever been of interest AZ (or its precursor companies), as opposed to IBEX which only contains compounds that have appeared in the medicinal chemistry literature. The discretionary nature of compound registration into the ISAC database may have resulted in some entries being far removed from the types of compound which generally end up making it into literature. It may also be the case that other organisations are developing drugs for different illnesses than AstraZeneca, and so the types of molecules required may be completely different. Alternatively, other organisations maybe approaching the same diseases but with a completely different solution.

The combination of a carbonyl substituent with a nitrogen-adjacent substituent (as outlined in Table 2.5 for the ISAC database) occurs often in the IBEX database (Table 2.12). The frequent occurrence of benzene groups in the ISAC database is also seen in the IBEX database. This is illustrated in Table 2.11, where all the aromatic groups found in combinations susceptible to base-catalysed racemisation are benzene rings.

### 2.4 Conclusions

The results from this chapter allow three main conclusions to be drawn.
Primarily, the vast majority of the stereogenic centres analysed have one proton substituent. This illustrates the importance of understanding the factors required for proton abstraction by base to occur and which substituents promote and supress it.

Secondly, following the definitions from Table 1.1, the vast majority of stereogenic centres found in the compounds investigated are not at risk from base-catalysed racemisation via proton abstraction. This is largely due to the presence on most stereogenic centres of an alkyl substituent which is unable to stabilise a negative charge.

Finally, of those frequently observed combinations of substituents on a stereogenic centre which do appear susceptible to racemisation, adjacent carbonyl, nitrogen and aromatic groups are commonly found. As a result the experimental studies that will follow this chapter were based around the following scaffold (Scheme 2.4).

X = OR, NHR

Scheme 2.4: Compounds to be investigated in Chapters 3 and 4.

### 2.5 Experimental

### 2.5.1 SMARTS Used for Analysis of Substituents

The SMARTS syntax used for substituent analysis is shown below. The recursive SMARTS definitions called upon in several categories are shown after the category definitions.

### 2.5.2 SMARTS Queries

The definitions in the SMARTS code shown in Section 2.5 .1 were used to interpret the SMILES strings from the AZ databases after processing using the 'chiral chopper' program (Section 2.2.1). The stereogenic centre in each molecule is replaced by a 'marker' Xenon atom and, as can be seen in the SMARTS code, this is used to identify the location of the stereogenic centre within each substituent.

The use of recursive SMARTS is well illustrated by the category 'other six-membered aromatic'. This category contains all six-membered aromatic groups other than benzene and the nitrogen-containing heterocycles displayed in Table 2.1. After initial SMARTS were written for each of these aromatics, a 'catch all' six-membered aromatic definition was written:

SIX_MEMBERED_GENERAI_DEF [Xe]alaaaaa1 10
A SMARTS definition was then written for 'other six-membered aromatic', which looks for SMILES strings which fit the definition of a six-membered aromatic group but are not any of the specific groups defined previously (benzene, pyridines etc.):

```
SIX_MEMBERED_GENERAL
[$SIX_MEMBERED_GENERAL_DEF;!$BENZENE;!$TRIAZINE;!$PYRADIZINE_3_4;!$PYRADIZI
NE_2_3;!$PYRAZINE;!$PYRIMIDINE_3_5;!$PYRIMIDINE_2_4;!$PYRIMIDINE_2_6;!$PYRI
\INE_PARA;!$PYRIDINE_META;!$PYRIDINE_ORTH] 1 1
```

Similar examples of recursive SMARTS were used in the definitions for differently substituted amide groups, as well as the 'other' category.

The 'chiral chopper' program also recognises the chirality found on sulphur atoms in sulfoxide and sulfilimine functional groups, on account of the sulphur lone pair (Scheme 2.5).

Sulfoxide

Sulfilimine

Scheme 2.5: Chirality in sulfoxide and sulfilimine functional groups.
When the 'chiral chopper' program encounters molecules containing these functional groups, it results in SMILES denoting a Xenon atom double bonded to either an oxygen (sulfoxide) or a nitrogen (sulfilimine). Therefore, when analysing the output of the SMARTS query it has to be taken into account that SMILES strings for these molecules will only have three substituents.

### 2.5.3 SMARTS Output

The output from the SMARTS query consists of a large .txt file with a molecule number for every compound listed in the database queried followed by a series of numbers, corresponding to each of the 52 categories of substituent tested for and how many instances of that group the compound contains. In order to check that the SMARTS code was recognising every substituent as one of the designated categories, the sum of the substituents was calculated for each molecule. If every substituent of a molecule has been categorised the sum is equal to 4 , except in cases where the stereogenic centre is not a carbon atom such as sulfoxides and sulfilimines (Section 2.5.2). This worked as an iterative process; the SMARTS output was analysed for cases where the sum of the groups was more or less than four and the structure of the original molecule was analysed. The SMARTS code was then rewritten to either 'tighten up' certain definitions (so it did not record substituents in more than one category) or new functional groups were coded for (either as a stand-alone category or to be classified as 'other').

Each stereogenic centre in the SMARTS output was given an identifier code, produced by stringing together the series of numbers corresponding to each substituent category. This results in all stereogenic centres with the same combinations of substituents having the same identifying code. The number of stereogenic centres bearing each combination of substituents could then be totalled.

The most frequently occurring combinations of substituents were then analysed, and using chemical intuition and the guidelines set by Testa et al. (Table 1.1) assessed for susceptibility to acid- or base-catalysed racemisation.

### 2.6 Appendix

### 2.6.1 Explanation of Syntax Used

### 2.6.1.1 SMILES

The information in the ISAC and IBEX databases is recorded using the SMILES ${ }^{1-8}$ (Simplified Molecular Input Line Entry Syntax) chemical language. Using SMILES, molecules and reactions can be represented using a series of ASCII characters. The basic structure of the language is as follows:

- Atoms within a molecule are represented by their atomic symbol inside square brackets.
- For elements within the 'organic subset' (Boron, Nitrogen, Carbon, Oxygen, Phosphorous, Sulphur and the halogens), the square brackets are not necessary if the number of hydrogens conforms to the lowest normal valence.
- Within square brackets, any attached hydrogens or formal charge must be specified.
- Aromaticity is signified by lowercase lettering.
- Bonds are assumed to be single unless specified otherwise. Molecular branches can be specified by enclosure within parentheses.
- Cyclic structures are represented by assigning a number to an atom and then referring back to it.
- Chirality is indicated by either @ or @@ designation of stereogenic centre.

Some examples of simple molecules represented by SMILES syntax are shown in Table 2.7.

Table 2.7: Examples of SMILES syntax.
Compound name

### 2.6.1.2 SMARTS

The SMARTS ${ }^{9,10}$ (Smiles Arbitrary Target Specification) chemical language is an extension of SMILES that enables sub-structure targeting of compounds in molecular databases to find a desired chemical 'motif'. All SMILES characters and properties are valid terms in SMARTS, which also includes logical operators (such as 'and', 'or' and 'not'). This allows queries to be made with the desired level of specificity. For example, using SMILES, methane can be written as C or [CH4]. A SMARTS search of C would result in a match for methane, but would also match for ethane, propane, or any compound in the database containing an aliphatic carbon. A SMARTS search of [ CH 4 ] would match only for methane. If one wanted to search for carbonyl containing compounds, the following SMARTS searches would give varying results:

- $\mathrm{C}=\mathrm{O}$ would return molecules containing a carbonyl (ketone, amide, etc.)
- $C C(=0) C$ would only return ketones
- $C C(=0) 0$ would return all esters and carboxylic acids
- $C C(=0)$ OC would only return esters

Some other important features of SMARTS are described below:

- "a" is any aromatic atom, " $A$ " is any aliphatic
- " $D$ " is any heavy atom (i.e. not hydrogen)
- E.g. [OD2] is oxygen bonded to any two heavy atoms
- "\#" can be used to define any atom of a specified atomic number
- E.g. [\#7] is any aromatic or aliphatic nitrogen
- "!" is the "not" logical operator
- E.g. [!C] is any atom that is not an aliphatic carbon
- "," is the "or" logical operator
- E.g. $[\mathrm{O}, \mathrm{N}]$ is any atom that is an aliphatic oxygen or carbon
- " $\delta$ " and ";" are both "and" logical operators. " $\alpha$ " is higher precedence than the "or" operator (","), ";" is lower precedence than "or". High precedence "and" is the default operator and may be omitted.
- $[C \&+1,+0]$ is an aliphatic carbon with +1 charge or any neutral atom
- $[C ;+1,+0]$ is an aliphatic carbon with +1 or neutral charge

The examples below show the range of specificity possible with SMARTS.
Aliphatic oxygen attached to carbon with any bond:

- $\mathrm{C} \sim \mathrm{O}$

Oxygen or nitrogen, with at least one hydrogen attached and not in a ring:

- [O,N;!H0; !R]

Oxygen double bonded to aliphatic carbon or nitrogen:

- $[O]=[C, N]$ or $[\# 6]=[C, N]$

Oxygen double bonded to aliphatic carbon or nitrogen, single bonded to an aromatic ring, with a halogen in meta position:

- [\#6] $=[\mathrm{C}, \mathrm{N}]-\mathrm{aaa}[\mathrm{F}, \mathrm{Cl}, \mathrm{Br}, \mathrm{I}]$

It is also possible to define SMARTS and then refer back to them. So-called recursive SMARTS are used to define an atomic environment which can be called upon using the \$ symbol. In the following example, a carbonyl group is defined and then referred back to when searching for a primary amide group:

CARBONYL_DEF
$C(=0) \quad 1 \quad 0$
PRIM_AMIDE [\$CARBONYL_DEF][ND1] 11
Recursive SMARTS were used in writing the search criteria for the analysis in this chapter. The numbers after the definition determine whether the SMARTS desire output or not. ' 10 ' after SMARTS code is used when something is defined to be called upon later and does not give any output. ' 1 1' after SMARTS code instructs the program to output whether the SMARTS have been found or not. It does this in the form of a ' 1 ' for yes, ' 0 ' for no.

### 2.6.2 Data Tables

Table 2.8: Details of all combinations of substituents within the most common 250 in ISAC, considered at risk of acid-catalysed racemisation.

| Combination of substituents on stereocentre |  | No. <br> stereocentres $^{\mathbf{a}}$ |  |
| :---: | :--- | :---: | :---: |
| $\mathbf{2 0}$ | 1 proton, 1 hydroxyl, 1 benzene, 1 alkyl |  | 16882 |
| $\mathbf{7 2}$ | 1 hydroxyl, 1 benzene, 2 alkyl |  | 3291 |
| $\mathbf{7 7}$ | 1 proton, 1 hydroxyl, 1 alkyl, 1 alkene | 2866 |  |
| $\mathbf{1 1 5}$ | 1 hydroxyl, 2 benzene, 1 alkyl | 1717 |  |
| $\mathbf{1 2 7}$ | 1 hydroxyl, 2 benzene, 1 alkyl and aromatic sub. tert. amide |  | 1502 |
| $\mathbf{1 3 4}$ | 1 proton, 1 hydroxyl, 1 five-membered aromatic, 1 alkyl |  | 1398 |
| $\mathbf{1 9 6}$ | 1 proton, 1 hydroxyl, 1 benzene, 1 dialkyl tert. amide | 861 |  |
| $\mathbf{2 0 3}$ | 1 proton, 1 hydroxyl, 1 benzene, 1 five-membered aromatic |  | 795 |
| $\mathbf{2 1 9}$ | 1 hydroxyl, 1 benzene, 1 alkyl, 1 dialkyl tert. amide | 661 |  |
| $\mathbf{2 4 9}$ | 1 proton, 1 hydroxyl, 1 alkyl, 1 ether | 544 |  |

## 3 Kinetic Studies on the Configurational Instability of $N$-Acetyl Arylglycine Esters

### 3.1 Introduction

The literature on instability of stereogenic centres (Chapter 1) combined with chemical intuition gives an insight into the structural features that may facilitate racemisation of drugs under physiological conditions. This information, in conjunction with the results from the analysis of AstraZeneca's compound libraries (Chapter 2), suggested several structures of interest. The focus in this chapter will be on the set of $N$-acetyl arylglycine ester derivatives illustrated in Scheme 3.1.

Scheme 3.1: Structures to be investigated in this chapter. $\mathrm{R}=$ methyl, ethyl and isopropyl esters, $\mathrm{Ar}=$ substituted benzenes and 2- and 3-thienyl groups.
$N$-acetyl arylglycine esters are of type R''R'RC-H, and hence could be susceptible to racemisation through base-catalysed proton abstraction mechanisms, as discussed in Chapter 1. All three substituents around the stereogenic centre can help stabilise a developing negative charge. Esters and aromatic groups can do this through delocalisation of the negative charge (Scheme 1.10). The amide group can do this through electrostatic interactions of a partial positive charge on the amide nitrogen with the negative charge built up during racemisation (Scheme 1.11b). By the guidelines set out by Testa et al., ${ }^{1-3}$ (Table 1.1) we would expect to see pharmaceutically relevant configurational instability due to the presence of three 'acidstrengthening' groups, one of which is classified as strongly so (ester).

Database mining studies showed that stereogenic centres deemed susceptible to basecatalysed racemisation commonly possess adjacent carbonyl, nitrogen and aromatic groups (Chapter 2). The particular combination of an adjacent ester, 'reverse' secondary amide and a benzene group is only the $437^{\text {th }}$ most frequently occurring combination of substituents in the ISAC database (appearing in 225 stereocentres).* However, each substituent appears frequently in compounds considered susceptible to base-catalysed racemisation. As a result, the effect of each substituent on the process of base-catalysed racemisation is of importance.

[^9]Several of the top selling pharmaceutical drugs on the market have stereogenic centres similar to that shown in Scheme 3.1. Stereogenic centres similar to the those under investigation in this chapter are found in the platelet aggregate inhibitor Clopidogrel, ${ }^{4,5}$ cholesterol regulator Ezetimibe, ${ }^{6}$ psychostimulant Methylphenidate ${ }^{7,8}$ and $\mathrm{ACE}^{\dagger}$ inhibitor Perindopril ${ }^{9}$ (Scheme 3.2).

Scheme 3.2: Drugs with similar stereogenic centres to the scaffold shown in
Scheme 3.1.
Mining studies of drug databases have shown that, although not as abundant as benzene rings, aromatic heterocycles are commonly found in drug molecules. ${ }^{10}$ Nitrogen-containing heterocycles are the most commonly found, followed by oxygen-containing and sulphur-containing heterocycles. ${ }^{11}$ Pyridine was found to be the second most frequently occurring ring system in the National Cancer Institute drug database (after benzene), appearing in $2.7 \%$ of molecules ( $>250,000$ drugs analysed). ${ }^{12}$ Thiophene is the most common sulphur-containing heterocycle found in the Comprehensive Medicinal Chemistry database. ${ }^{11}$ An example of a thiophene containing drug is the antidepressant Duloxetine ${ }^{13}$ (Scheme 3.3).

[^10]

Scheme 3.3: Structure of Duloxetine.
Because of their abundance in drug molecules, it is desirable to incorporate compounds containing heterocycles into our analysis. Thiophenes were chosen for analysis in this chapter due to the commercial availability of appropriate starting materials. Although thiophenes are not the most desired heteroaromatics for study, analysis of their behaviour will allow insight into how the effect of heteroaromatic substituents on a stereogenic centre may differ from the effect of benzene derivatives.

### 3.2 Aims

This chapter has five main aims.
First, to determine the rates of racemisation and proton-deuterium exchange (H/D exchange) for compounds of general structure illustrated in Scheme 3.1, under conditions analogous to those found in the body. Evaluation of these rates will inform as to whether or not stereogenic centres such as those found in the compounds under analysis are at risk of configurational instability in the body.

Second, to analyse the effect changes in conditions have on the rate constants of configurational instability.

Third, resulting from the previous point, to determine whether configurational instability is general- or specific-base catalysed.

Fourth, to investigate the effects each substituent has on configurational stability. Quantifying the effect of slight changes in molecular structure on the rate constants of H/D exchange will afford insight into the importance of each substituent in the process.

Fifth, to determine the mechanism by which racemisation and H/D exchange takes place. This will also be informed by the effect of different substituents on the rate constants for racemisation and $\mathrm{H} / \mathrm{D}$ exchange.

### 3.3 Synthesis of Compounds for Analysis

A set of $N$-acetyl arylglycine methyl esters 3a-I was selected for analysis (Scheme 3.4).

3a-h
$\mathrm{X}=\mathbf{a}) \mathrm{H}$, b) $p-\mathrm{OH}, \mathbf{c}) p-\mathrm{Me}, \mathbf{d}) p-\mathrm{F}$,
e) $p-\mathrm{Cl}, \mathbf{f}) m-\mathrm{F}, \mathbf{g}) m-\mathrm{F}, \mathbf{h}) p-\mathrm{CF}_{3}$

& \quad \text { e) } p-\mathrm{Cl}, \mathbf{g}) m-\mathrm{F}, \text { h) } p-\mathrm{CF}_{3}
\end{aligned}
$$

Scheme 3.6: $N$-acetyl phenylglycines 4a, c-e, g-h.
These compounds were also synthesised from commercially available arylglycine starting materials, as displayed in Scheme 3.7.

Scheme 3.7: Synthetic route to compounds 4a, c-e, g-h.
Enantiopure analogues of $\mathbf{3 a}, \mathbf{3 e}, \mathbf{4 a}$ and $\mathbf{4 e}$ were synthesised in the same manner from enantiopure starting materials.

### 3.4 Results and Discussion

### 3.4.1 Initial Proton-Deuterium Exchange Experiments

As discussed in Chapter 1, configurational instability for stereogenic centres of type R''R'RC-H can be monitored through H/D exchange experiments. If deuterium incorporation at the stereogenic centre is observed then this strongly suggests that the compound is not configurationally stable. The use of $\mathrm{H} / \mathrm{D}$ exchange experiments as a model for racemisation also has the advantage that enantiopure or enantioenriched compounds do not need to be used.

Compounds 3a-j were placed in deuterated buffers and incubated at $37{ }^{\circ} \mathrm{C}$. A range of different phosphate buffer strengths were used. Generally, buffers with $\mathrm{pH}^{* *} 7.4$ were used. ${ }^{\ddagger 14-16}$ Some experiments were undertaken at $\mathrm{pH}^{* *} 7.8$, in order to evaluate the relative involvement of the different phosphate species present $\left(\mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}\right.$and $\left.\mathrm{HPO}_{4}{ }^{2-}\right)$ in $\mathrm{H} / \mathrm{D}$ exchange. A constant ionic strength of 1 M was used. The reaction was monitored over time using ${ }^{1} \mathrm{H}$ NMR spectroscopy. The extent of $\mathrm{H} / \mathrm{D}$ exchange at the stereogenic centre is measured by looking for a decrease in the intensity of the peak corresponding to the proton bound to the stereogenic centre. The intensity of the peak is calculated relative to the peak for the protons on the benzene ring. It is assumed that no deuterium incorporation takes place on the benzene ring and, thus, that the intensity of the aromatic protons remains constant over time.

### 3.4.2 Reaction Scheme

H/D exchange at the stereogenic centre was observed for all compounds 3a-l. Ester hydrolysis was also seen for each compound. As the ester was being hydrolysed, a new peak in the ${ }^{1} \mathrm{H}$ NMR spectrum appeared. This peak corresponds to a proton bound to the stereogenic centre for the relevant hydrolysis products $\mathbf{4 a - h}, \mathbf{k}-\mathbf{l}$. Confirmation that this new peak was a result of ester hydrolysis was obtained by comparison of the chemical shift of the new peak in the ${ }^{1} \mathrm{H}$ NMR spectrum, with that seen for the synthesised corresponding $N$-acetyl phenylglycine.

[^11]Following ester hydrolysis, no further $\mathrm{H} / \mathrm{D}$ exchange is seen at the stereogenic centre. Confirmation that no H/D exchange at the stereogenic centre occurs for 4a-h, k-l was obtained by monitoring $\mathbf{4 h}$ under the same conditions. No decrease in the intensity of the peak corresponding to the proton bound to the stereogenic centre was seen after 30 days for compound $\mathbf{4 h}$, indicating no $\mathrm{H} / \mathrm{D}$ exchange occurs. As the $p-\mathrm{CF}_{3}$ aromatic substituent in $\mathbf{4 h}$ is the most electron withdrawing substituent analysed, it can be concluded that if $\mathrm{H} / \mathrm{D}$ exchange does not occur for this compound, it will not for any of the $N$-acetyl phenylglycines $\mathbf{4 a - h}, \mathbf{k}-\mathbf{l}$ (cf. Section 1.8.2). The observation that no further H/D exchange occurs is consistent with the classification of a carboxylate group as enhancing configurational stability, because of unfavourable interactions between the carboxylate anion and negative charge built up during H/D exchange (Scheme 1.15). Therefore, the reaction scheme for compound 3a in deuterated buffers can be summarised as in Scheme 3.8.

Scheme 3.8: Reaction of 3a in deuterated buffer. Superscript letters in compound numbering refer to the nature of the hydron bound to the stereogenic centre in molecule.

The reaction profile in Scheme 3.8 also applies to compounds $\mathbf{3 b} \mathbf{b} \mathbf{j}$.
Despite ester hydrolysis, there is negligible difference in the chemical shift of the protons bound to the benzene ring between compounds 3 and 4 . The total intensity of the peaks from
the aromatic groups remains constant over time. Thus, when calculating relative integrals for protons bound to the stereogenic centre for both compounds, they are relative to the intensity of aromatic protons from both species.

### 3.4.3 Determination of Rate Constants of H/D Exchange and Hydrolysis

Observed rate constants for the disappearance of start material protonated at the stereogenic centre were obtained for compounds 3a-h. Each compound was analysed at a range of buffer concentrations and $\mathrm{pH}^{* *}$ 's, at an ionic strength of 1 M and temperature of $37^{\circ} \mathrm{C}$. Rate constants for $H / D$ exchange and hydrolysis were derived from the observed rate constants as described in the experimental (Section 3.6.3.3). The observed rate constants and the derived rate constants for $\mathrm{H} / \mathrm{D}$ exchange and hydrolysis of 3a are summarised in Table 3.1.

Table 3.1: Rate constants for $\mathrm{H} / \mathrm{D}$ exchange and for hydrolysis of $\mathbf{3 a}$ in $\mathrm{D}_{2} \mathrm{O}$ buffers at $37^{\circ} \mathrm{C}$, $I=1 \mathrm{M}$.

| $\mathbf{p H} * *$ | phosphate <br> conc. $/ \mathbf{M}$ | $\left[\mathrm{HPO}_{4}{ }^{2-}\right]$ <br> conc. $/ \mathbf{M}$ | $\boldsymbol{k}_{\text {obs }} \times \mathbf{1 0}^{\mathbf{6}} / \mathbf{s}^{-\mathbf{1}}$ | $\boldsymbol{k}_{\text {deut }} \times \mathbf{1 0}^{6} / \mathbf{s}^{-\mathbf{1}}$ | $\boldsymbol{k}_{\text {hyd }} \times \mathbf{1 0} \mathbf{0}^{6} / \mathbf{s}^{-\mathbf{1}}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 7.4 | 0.050 | 0.030 | $3.47 \pm 0.15$ | $1.36 \pm 0.18$ | $2.11 \pm 0.09$ |
| 7.4 | 0.100 | 0.061 | $4.10 \pm 0.13$ | $1.82 \pm 0.15$ | $2.28 \pm 0.08$ |
| 7.4 | 0.200 | 0.122 | $4.91 \pm 0.08$ | $2.80 \pm 0.09$ | $2.11 \pm 0.04$ |
| 7.4 | 0.250 | 0.152 | $5.52 \pm 0.16$ | $3.25 \pm 0.17$ | $2.27 \pm 0.07$ |
| 7.8 | 0.200 | 0.159 | $7.03 \pm 0.14$ | $3.57 \pm 0.16$ | $3.46 \pm 0.07$ |
| 7.4 | 0.300 | 0.182 | $6.16 \pm 0.11$ | $3.64 \pm 0.12$ | $2.53 \pm 0.05$ |
| 7.8 | 0.355 | 0.282 | $10.22 \pm 0.18$ | $5.61 \pm 0.19$ | $4.61 \pm 0.08$ |

Tables analogous to Table 3.1 for $\mathbf{3 b} \mathbf{- h}$ can be found in the appendix (Section 3.7.1.1).
To confirm the method of analysis, the rate constant for hydrolysis of 3a was also determined through HPLC. The rate constant of hydrolysis ( $k_{\text {hyd }}$ ) of 3a in $\mathrm{D}_{2} \mathrm{O}$ buffer of $\mathrm{pH}^{* *} 7.4$, phosphate concentration $0.2 \mathrm{M}, I=1 \mathrm{M}$ at $37^{\circ} \mathrm{C}$ was determined to be $(2.14 \pm 0.05) \times 10^{-6} \mathrm{~s}^{-1}$ (see experimental Section 3.6.5). This value compares favourably with the value of $k_{\text {hyd }}$ determined under these conditions through ${ }^{1} \mathrm{H}$ NMR spectroscopy, of $(2.11 \pm 0.04) \times 10^{-6} \mathrm{~s}^{-1}$.

### 3.4.4 Nature of Base-Catalysis

For each compound $\mathbf{3 a} \mathbf{a} \mathbf{h}$, the rate constant for deuteration was plotted as a function of the concentration of the basic component of the buffer (Figure 3.1 for 3a).

Figure 3.1: Variation of $k_{\text {deut }}$ of 3a with $\left[\mathrm{HPO}_{4}{ }^{2-}\right]$ at $37{ }^{\circ} \mathrm{C}, I=1 \mathrm{M}$, (■)
$\mathrm{pH}^{* *} 7.4,(\mathbf{\Delta}) \mathrm{pH}^{* *} 7.8$.
Figure 3.1 shows a linear increase in the rate constant for $\mathrm{H} / \mathrm{D}$ exchange as a function of the concentration of the basic buffer component. This linear increase suggests that $\mathrm{H} / \mathrm{D}$ exchange is subject to general-base catalysis by phosphate dianion. The experimental rate constant for deuteration follows the rate law given by eqn (3.1).

$$
\begin{equation*}
k_{\text {deut }}=k_{0}+k_{\mathrm{OH}}\left[\mathrm{OH}^{-}\right]+k_{\mathrm{gb}}\left[\mathrm{HPO}_{4}{ }^{2-}\right] \tag{3.1}
\end{equation*}
$$

where $k_{\text {deut }}$ is the observed rate constant for deuteration, $k_{0}$ is the rate constant of the uncatalysed reaction, $k_{\mathrm{OH}}$ is the rate constant of the hydroxide-catalysed deuteration reaction and $k_{\mathrm{gb}}$ is the rate constant of the phosphate dianion-catalysed deuteration reaction.

The gradient of the line in Figure 3.1 corresponds to the rate constant for $\mathrm{H} / \mathrm{D}$ exchange by general-base catalysis. The intercept with the $y$-axis corresponds to the sum of the uncatalysed and hydroxide-catalysed $\mathrm{H} / \mathrm{D}$ exchange reaction, $k_{0}$ ' (eqn 3.2).

$$
\begin{equation*}
k_{0}{ }^{\prime}=k_{0}+k_{\mathrm{OH}}\left[\mathrm{OH}^{-}\right] \tag{3.2}
\end{equation*}
$$

For 3a, the non-zero $y$-axis intercept suggests a degree of $\mathrm{H} / \mathrm{D}$ exchange proceeding by non-general-base catalysed pathways. As Figure 3.2 shows, not all compounds 3b-h display this non-zero $y$-axis intercept.

Figure 3.2: Relationship between $k_{\text {deut }}$ and basic buffer component for a) $\mathbf{3 b}$, b) $\mathbf{3 c}$, c) $\mathbf{3 d}$, d) $\mathbf{3 e}$, e) $\mathbf{3 f}$, f) $\mathbf{3 g}$, g) $\mathbf{3 h}$, at (■) $\mathrm{pH}^{* *} 7.4$ and ( $\mathbf{( 1 )} \mathrm{pH}^{* *} 7.8$ at $37^{\circ} \mathrm{C}, I=1 \mathrm{M}$.

The data from Figure 3.1 and Figure 3.2 is summarised in Table 3.2.

Table 3.2: $k_{\mathrm{gb}}$ and $k_{0}{ }^{\prime}$ for $\mathbf{3 a - h}$, at $\mathrm{pH}^{* *} 7.4$ and $7.8,37^{\circ} \mathrm{C}, I=1 \mathrm{M}$.

| Compound | $k_{\mathrm{gb}} / \mathrm{s}^{-1} \mathbf{M}^{-1}$ | $k_{0} / \mathbf{s}^{-1}$ |
| :---: | :---: | :---: |
| 3 a | $(1.64 \pm 0.09) \times 10^{-5}$ | $(8.05 \pm 1.28) \times 10^{-7}$ |
| 3b | $(6.01 \pm 0.72) \times 10^{-6}$ | $(0.24 \pm 1.05) \times 10^{-7}$ |
| 3 c | $(1.03 \pm 0.06) \times 10^{-5}$ | $(4.47 \pm 5.92) \times 10^{-7}$ |
| 3d | $(2.20 \pm 0.13) \times 10^{-5}$ | $(1.92 \pm 1.54) \times 10^{-7}$ |
| 3 e | $(7.47 \pm 0.38) \times 10^{-5}$ | $(9.37 \pm 4.71) \times 10^{-7}$ |
| 3 f | $(1.40 \pm 0.05) \times 10^{-4}$ | $(1.48 \pm 0.50) \times 10^{-6}$ |
| 3g | $(1.60 \pm 0.06) \times 10^{-4}$ | $(4.68 \pm 4.53) \times 10^{-7}$ |
| 3h | $(5.15 \pm 0.13) \pm 10^{-4}$ | $(5.01 \pm 0.98) \times 10^{-7}$ |

Table 3.2 shows that for $\mathbf{3 b}$ and $\mathbf{3 c}, k_{0}{ }^{\prime}$ is zero within error margins and most other compounds are not too far away from this. A significant value for $k_{0}{ }^{\prime}$ is only seen for $\mathbf{3 a}$ and 3h. If specific-base catalysis were occurring to a significant extent, data from the experiments undertaken at $\mathrm{pH}^{* *} 7.8$ would not fall on the same line of best fit with the experiments at $\mathrm{pH}^{* *} 7.4$, but would appear above the others. However, for all compounds 3a-h the data points obtained at $\mathrm{pH}^{* *} 7.8$ fit with those seen at $\mathrm{pH}^{* *} 7.4$. As a result, specific-base catalysis can be ignored for the $\mathrm{pH}^{* *}$ tested here, and analysis will focus on general-base catalysis by $\mathrm{HPO}_{4}{ }^{2-}$ ions.

Table 3.2 shows that the rate constants for $\mathrm{H} / \mathrm{D}$ exchange are greater for compounds with more electron-withdrawing substituents. Approximate half-lives of deuteration in $0.3 \mathrm{M}_{2} \mathrm{O}$ phosphate buffers at $\mathrm{pH}^{* *} 7.4, I=1 \mathrm{M}$ at $37^{\circ} \mathrm{C}$, are given in Table 3.3.

Table 3.3: Half-lives of H/D exchange for 3a-h in $\mathrm{D}_{2} \mathrm{O} 0.3 \mathrm{M}$ phosphate buffers of $\mathrm{pH}^{* *} 7.4$, $I=1 \mathrm{M}, 37^{\circ} \mathrm{C}$.

| Compound | Aryl Substituent | $\boldsymbol{t}_{\mathbf{1 / 2}} \mathbf{o f}$ deuteration / $\mathbf{h}$ |
| :---: | :---: | :---: | :---: |
| $\mathbf{3 a}$ | - | 62.7 |
| 3b | $p-\mathrm{OH}$ | 175.9 |
| $\mathbf{3 c}$ | $p-\mathrm{Me}$ | 94.7 |
| $\mathbf{3 d}$ | $p-\mathrm{F}$ | 48.0 |
| $\mathbf{3 e}$ | $p-\mathrm{Cl}$ | 14.2 |
| $\mathbf{3 f}$ | $m-\mathrm{F}$ | 7.1 |
| $\mathbf{3 g}$ | $m-\mathrm{Cl}$ | 6.7 |
| $\mathbf{3 h}$ | $p-\mathrm{CF}_{3}$ | 2.0 |

Table 3.3 shows that H/D exchange at the stereogenic centre, and hence racemisation, of 3a-h takes place on a pharmaceutically relevant timescale. This is particularly true for compounds with electron-withdrawing ring substituents.

### 3.4.5 Hydrolysis

In contrast to $\mathrm{H} / \mathrm{D}$ exchange, hydrolysis appears much more dependent on $\mathrm{OH}^{-}$concentration. Plots of $k_{\text {hyd }}$ against [ $\mathrm{HPO}_{4}{ }^{2-}$ ] (Figure 3.3) do not show a good correlation for all compounds. This is especially true for experiments undertaken at $\mathrm{pH}^{* *} 7.8$, for which $k_{\text {hyd }}$ is generally much higher than for experiments at $\mathrm{pH}^{* *} 7.4$. The data from Figure 3.3 is summarised in Table 3.4

Figure 3.3: Relationship between $k_{\text {hyd }}$ and basic buffer component for a) 3a, b) $\mathbf{3 b}$, c) $\mathbf{3 c}$, d) $\mathbf{3 d}$, e) $\mathbf{3 e}$, f) $\mathbf{3 f}, \mathrm{g}$ ) $\mathbf{3 g}$, h) $\mathbf{3 h}$, at (■) $\mathrm{pH}^{* *} 7.4$ and ( $\mathbf{4}$ ) $\mathrm{pH}^{* *}$
7.8 at $37^{\circ} \mathrm{C}, I=1 \mathrm{M}$. (-) fitted solely with $\mathrm{pH} * * .4$ data points.

Table 3.4: $k_{\mathrm{gb}(\text { hyd })}$ and $k_{0}{ }^{\prime}{ }_{(\text {hyd })}$ for $\mathbf{3 a - h}$, at $\mathrm{pH}^{* *} 7.4,37^{\circ} \mathrm{C}, I=1 \mathrm{M}$.

| Compound | $\boldsymbol{k}_{\mathrm{gb} \text { (hyd) }} / \mathbf{s}^{-1} \mathbf{M}^{-1}$ | $k_{0}{ }^{\prime}(\mathrm{hyd}) / \mathrm{s}^{-1}$ |
| :---: | :---: | :---: |
| 3a | $(2.66 \pm 0.55) \times 10^{-6}$ | $(1.92 \pm 0.08) \times 10^{-6}$ |
| 3b | $(2.35 \pm 0.47) \times 10^{-6}$ | $(1.52 \pm 0.07) \times 10^{-6}$ |
| 3 c | $(7.07 \pm 0.38) \times 10^{-6}$ | $(8.27 \pm 0.38) \times 10^{-7}$ |
| 3d | $(1.29 \pm 0.08) \times 10^{-5}$ | $(1.43 \pm 0.09) \times 10^{-6}$ |
| 3 e | $(2.05 \pm 0.18) \times 10^{-5}$ | $(1.69 \pm 0.20) \times 10^{-6}$ |
| 3 f | $(1.30 \pm 0.11) \times 10^{-5}$ | $(2.73 \pm 0.14) \times 10^{-6}$ |
| 3g | $(1.05 \pm 0.16) \times 10^{-5}$ | $(2.74 \pm 0.13) \times 10^{-6}$ |
| 3h | $(4.62 \pm 0.25) \pm 10^{-6}$ | $(7.19 \pm 3.57) \times 10^{-6}$ |

Table 3.4 shows that, although there appears to be some general-base catalysis of hydrolysis for 3a-h, it is less than that seen for H/D exchange. It is also noticeable that general-base catalysed hydrolysis shows no apparent increase for the structures with more electronwithdrawing aromatic substituents. A possible explanation for this is that the reaction site for hydrolysis is further away from the aromatic ring than the site of $\mathrm{H} / \mathrm{D}$ exchange. The values of $k_{0}$ ' are larger in magnitude for the hydrolysis of 3a-h than for $\mathrm{H} / \mathrm{D}$ exchange. It was observed that the values of $k_{\text {hyd }}$ at $\mathrm{pH}^{* *} 7.8$ are larger than would be expected if hydrolysis was solely general-base catalysed, suggesting a significant degree of specific-base catalysis by hydroxide ions.

### 3.4.6 Hammett Analysis

Hammett plots of the rate constants of general base-catalysed H/D exchange for 3a-h (from Table 3.2) as a function of $\sigma$ - and $\sigma^{-}$-constants were constructed (Figure 3.4).

Figure 3.4: Hammett plots for data from Table 3.2 for general base-catalysed H/D exchange at the stereogenic centres of 3a-h, in $\mathrm{D}_{2} \mathrm{O}$ phosphate buffers of $I=1 \mathrm{M}$ at $37^{\circ} \mathrm{C}$ a) as a function of $\sigma$-values (一) line of best fit for all data points, $\rho=2.50 \pm 0.03, \mathrm{R}^{2}=0.979$, (一) line of best fit for data points where $\sigma \geq 0, \rho=2.79 \pm 0.04, \mathrm{R}^{2}=0.998$. b) as a function of $\sigma^{-}$-values, $(-) \rho=2.07 \pm 0.02, \mathrm{R}^{2}=0.984$. Hammett constants from Table 1.5. ${ }^{17}$

The linear nature of both plots in Figure 3.4 suggests a common mechanism of $\mathrm{H} / \mathrm{D}$ exchange for compounds 3a-h. The positive gradients seen in Figure 3.4 confirms that negative charge is built up on the reaction centre during H/D exchange. Using $\sigma$-constants, the data shows a good linear correlation for electron-withdrawing substituents ( $\sigma>0$ ) but this does not hold for electron-donating substituents $\mathbf{3 b}$ and $\mathbf{3 c}(p-\mathrm{OH}$ and $p$-Me). Figure 3.4 shows a better overall correlation to $\sigma^{-}$-values than with standard $\sigma$-values. The better correlation with $\sigma^{-}$is attributed to direct conjugation of the site of reaction to the aromatic ring. Negative charge built up during H/D exchange can be resonance-delocalised through the phenyl group onto the substituent.

Although Figure 3.4 shows a better correlation with $\sigma^{-}$-values than with $\sigma$-values for general base-catalysed H/D exchange of 3a-h, it should be noted that for most of the substituents analysed there is not a great deal of difference between $\sigma$ and $\sigma^{-}$. Of the eight different compounds, only three have different $\sigma$ - and $\sigma^{-}$-values and the largest difference $\left(p-\mathrm{CF}_{3}\right)$ is only 0.11 units. This small difference makes conclusively determining whether the data correlates better with one set of substituent constants or with another difficult. Ideally, a substituent such as a nitro group ( $\sigma$ - and $\sigma^{-}$-values 0.78 and 1.27 respectively) would be included in the Hammett analysis, to simplify determination of which set of substituent constants is best for the data. Unfortunately, the appropriately substituted phenylglycine starting material is not commercially available and efforts to synthesise it were unsuccessful.

In circumstances where data appears to fit somewhere in between $\sigma$ - and $\sigma^{-}$-values (or indeed $\sigma$ - and $\sigma^{+}$-values) the Yukawa-Tsuno equation (Section 1.8.2.2.3) is used, to acknowledge the possible presence of an intermediate degree of resonance interaction. However, as the difference in $\sigma$ - and $\sigma^{-}$-values for 3a-h is only small there is little value in carrying out an analysis in terms of the Yukawa-Tsuno equation for the current dataset.

The magnitude of $\rho$ from Figure 3.4 gives us an insight into the degree of negative charge built up on the reaction centre during H/D exchange. The value of $\rho=2.07$ can be contrasted with that of $\rho=1.15$ for the racemisation of arylglycines in phosphate buffers, determined by Smith and Sivakua. ${ }^{18}$ The authors consider this $\rho$ value for arylglycine racemisation to be quite low, suggesting little charge stabilisation is derived from the aryl group. This is because either very little charge is built up on the reaction centre or, as considered more likely by the authors, stabilisation results from moieties other than the aryl substituents. They conclude that major stabilisation comes from the reaction medium (water) and the adjacent $-\mathrm{NH}_{3}{ }^{+}$group. ${ }^{\S}$ The $\mathrm{S}_{\mathrm{E}} 1$ mechanism was proposed as the mechanism of racemisation for arylglycines, based on the relative ratio of the rate constants of racemisation and $\mathrm{H} / \mathrm{D}$ exchange (Section 1.3). A similarly small $\rho$ of 0.83 was determined for the ionisation of arylnitromethanes $\left(\mathrm{ArCH}_{2} \mathrm{NO}_{2}\right)$ in water at $25^{\circ} \mathrm{C}$ by Bordwell and Boyle. ${ }^{19,20}$ The small $\rho$ value was believed to be a result of the adjacent nitro group providing major stabilisation.

Conversely, a $\rho$ value of 3.58 for the racemisation of profen thioesters catalysed by trioctylamine in isooctane at $45^{\circ} \mathrm{C}$ was determined by Chen et al. (Scheme 3.9). ${ }^{21}$

Scheme 3.9: Racemisation of profen thioesters in isooctane via proton abstraction with trioctylamine base. $\rho=3.58$.

The higher $\rho$ value for the reaction in Scheme 3.9 can be attributed to two factors. Firstly, the methyl group adjacent the site of negative charge build-up (the stereogenic centre) cannot stabilise a charge in the manner that an -NHAc group (compounds 3a-h), an $-\mathrm{NH}_{3}{ }^{+}$group (reference 18) or an $-\mathrm{NO}_{2}$ group (reference 19) does. Therefore the reliance on charge

[^12]stabilisation by the aryl substituent is greater. Secondly, the reaction medium in this case is isooctane. This nonpolar alkane cannot stabilise a charge in the manner that water can in the other cited examples, giving even greater importance to the stabilisation by the aryl substituent.

### 3.4.7 Variation of Ester Substituent

The effect of the nature of the ester substituent was investigated through comparison of rate constants of $\mathrm{H} / \mathrm{D}$ exchange and hydrolysis for compounds $\mathbf{3 a}, \mathbf{3 i}$ and $\mathbf{3 j}$. The rate constants are summarised in Table 3.5.

Table 3.5: Rate constants of $\mathbf{3 a}, \mathbf{3 i}$ and $\mathbf{3 j}$ in $\mathrm{pH}^{* *} 7.4 \mathrm{D}_{2} \mathrm{O}$ buffers of 0.3 M phosphate concentration, at $37^{\circ} \mathrm{C}, I=1 \mathrm{M}$.

| Compound | $k_{\text {obs }} \times 10^{6} / \mathrm{s}^{-1}$ | $k_{\text {deut }} \times 10^{6} / \mathrm{s}^{-1}$ | $k_{\text {hyd }} \times 10^{6} / \mathrm{s}^{-1}$ |
| :---: | :---: | :---: | :---: |
| 3a | $6.16 \pm 0.11$ | $3.64 \pm 0.12$ | $2.53 \pm 0.05$ |
| $3 i$ | $2.85 \pm 0.08$ | $1.91 \pm 0.08$ | $0.95 \pm 0.03$ |
| 3j | $0.98 \pm 0.04$ | $0.88 \pm 0.04$ | $0.10 \pm 0.01$ |

As expected, rate constants of hydrolysis were found to decrease as the ester substituent increased in size. This decrease is attributed to steric hindrance disfavouring general- and specific- base catalysed hydrolysis by blocking attack at the carbonyl carbon. ${ }^{22,}{ }^{23}$ Rate constants of H/D exchange also decreased with increasing size of alkyl ester substituent. As with hydrolysis, this decrease is likely due to steric hindrance blocking base-catalysed proton abstraction at the stereogenic centre. As many drug molecules are much larger in molecular weight and have a much larger 'framework' than those analysed here, the observation that racemisation can be retarded by steric bulk may become important when assessing the racemisation risk of prototype drugs.

The rate constant for hydrolysis shows a larger decrease with increasing bulk of the ester substituent than the rate constant for $\mathrm{H} / \mathrm{D}$ exchange. The rate constant of hydrolysis drops by an approximate factor of 25 when the methyl ester is replaced by an isopropyl ester ( $\mathbf{3 a}$ to $\mathbf{3 j}$ ), whereas the rate constant for H/D exchange drops by an approximate factor of 4 . This observation is probably due to the proximity of the ester alkyl substituent being varied to the site of reaction, which is closer for hydrolysis (carbonyl carbon) than for H/D exchange (stereogenic centre). As a result, the increasing steric hindrance from the ester group will have
a greater impact on the rate constant of hydrolysis than it will on the rate constant of H/D exchange.

### 3.4.8 Mechanism of Racemisation

Comparison between the rate constants for racemisation and $\mathrm{H} / \mathrm{D}$ exchange can inform as to by which mechanism racemisation is occurring. The two most likely mechanisms of racemisation are known as $\mathrm{S}_{\mathrm{E}} 1$ and $\mathrm{S}_{\mathrm{E}} 2$. Previous studies on compounds similar to 3a-h have generally concluded that racemisation occurs through an $\mathrm{S}_{\mathrm{E}} 1$ mechanism, ${ }^{18,24,25}$ although an example of racemisation by the $\mathrm{S}_{\mathrm{E}} 2$ mechanism has been reported. ${ }^{26}$ The $\mathrm{S}_{\mathrm{E}} 1$ and $\mathrm{S}_{\mathrm{E}} 2$ mechanisms can be distinguished by comparison of the rate constants of racemisation and H/D exchange (Section 1.3).

Ester hydrolysis of $\mathbf{3 a - h}$ is a problem when trying to determine the rate constant of racemisation. The hydrolysis reaction results in the presence of more than one species (ester and carboxylate) in the reaction mixture at the same time. Ideally, chiral HPLC is used to determine the concentration of each of the enantiomers of ester and carboxylate throughout the reaction, however this technique was unavailable. Multiple species in the reaction mixture makes analysis through spectroscopy difficult, as distinguishing between the signals from the ester and carboxylate species is a problem. However, a way around this problem is to only look at the final composition of the reaction mixture, once hydrolysis is complete. The enantiomeric excess of the final, fully hydrolysed product can be determined through CD spectroscopy (Section 1.10.3). Comparison of the ee of the fully hydrolysed compound with the final proportion of molecules deuterated at the stereogenic centre (i.e. proportion that have undergone $\mathrm{H} / \mathrm{D}$ exchange prior to hydrolysis) affords information on the mechanism by which H/D exchange is taking place. The expected observations for the $\mathrm{S}_{\mathrm{E}} 1$ and $\mathrm{S}_{\mathrm{E}} 2$ mechanisms are outlined in eqns (3.3) and (3.4), respectively.

$$
\begin{align*}
& Q_{\mathrm{f}}^{\mathrm{H}}=e e_{\mathrm{f}}  \tag{3.3}\\
& Q_{\mathrm{r}}^{\mathrm{H}}>e e_{\mathrm{f}} \tag{3.4}
\end{align*}
$$

where $Q_{\mathrm{f}}{ }^{\mathrm{H}}$ is the percentage of molecules protonated at the stereogenic centre after hydrolysis is complete and $e e_{\mathrm{f}}$ is the enantiomeric excess of hydrolysed species after hydrolysis is complete. The theoretical basis for equations 3.3 and 3.4 is outlined in Appendix Section 3.7.1.

### 3.4.8.1 Comparison of Data from CD and ${ }^{1}$ H NMR Spectroscopy Experiments

H/D exchange/racemisation experiments in deuterated buffer were undertaken for enantiopure $(R)$-3a and (S)-3e. H/D exchange was monitored through ${ }^{1} \mathrm{H}$ NMR spectroscopy and hydrolysis was followed by HPLC. Once hydrolysis was complete, the final ee was determined through CD spectroscopy. Comparisons of $Q_{f}^{H}$ with $e e_{f}$ for 3a and 3e are displayed in Table 3.6.

Table 3.6: Comparison of $Q_{\mathrm{f}}^{\mathrm{H}}$ with $e e_{\mathrm{f}}$ for $\mathbf{3 a}$ and $\mathbf{3 e}$ in $\mathrm{D}_{2} \mathrm{O}$ buffers of $\mathrm{pH}^{* *} 7.4,0.3 \mathrm{M}$ phosphate concentration, $I=1 \mathrm{M}$ at $37^{\circ} \mathrm{C}$.

| Compound | X-substituent | $Q_{f}{ }^{\text {H }}$ | $e e_{\text {f }}$ |
| :---: | :---: | :---: | :---: |
| 3a | - | $41.1 \pm 0.3$ \% | $45.5 \pm 2.1$ \% |
| 3 e | $p-\mathrm{Cl}$ | $26.8 \pm 0.6$ \% | $30.2 \pm 1.4 \%$ |

Table 3.6 shows that $Q_{\mathrm{f}}{ }^{\mathrm{H}}$ and $e e_{\mathrm{f}}$ for both $\mathbf{3 a}$ and $\mathbf{3 e}$ are approximately the same. This strongly suggests that $\mathrm{H} / \mathrm{D}$ exchange, and hence racemisation, occur via an $\mathrm{S}_{\mathrm{E}} 1$ mechanism. Although the values determined for $Q_{\mathrm{f}}{ }^{\mathrm{H}}$ and $e e_{\mathrm{f}}$ for both compounds do not exactly match, in both cases $e e_{\mathrm{f}}$ is slightly higher than $Q_{\mathrm{f}}{ }^{\mathrm{H}}$. If the $\mathrm{S}_{\mathrm{E}} 2$ mechanism were taking place, $Q_{\mathrm{f}}{ }^{\mathrm{H}}$ would be higher than $e e_{\mathrm{f}}$, and significantly so given the comparative rates of $k_{\text {deut }}$ and $k_{\text {hyd }}$ determined by ${ }^{1} \mathrm{H}$ NMR and HPLC for 3a and 3e. As discussed in Section 1.3, there are known examples where deuteration can proceed with retention of stereochemistry (isoinversion). ${ }^{27,28}$ The small discrepancy between $Q_{\mathrm{f}}{ }^{\mathrm{H}}$ and $e e_{\mathrm{f}}$ may be due to isoinversion or experimental error.

Although the $e e_{\mathrm{f}}$ could only be determined for $\mathbf{3 a}$ and $\mathbf{3 e}$, it seems safe to extrapolate this result to all differently substituted 3 compounds. This is based on the conclusion from the linear Hammett plot (Figure 3.4) that all compounds 3a-h share a common mechanism of H/D exchange.

### 3.4.8.2 Mechanistic Conclusions

Overall, it can be concluded that general-base catalysed H/D exchange and racemisation of 3a-h proceed through the $\mathrm{S}_{\mathrm{E}} 1$ mechanism, under the conditions studies here. This is based on three observations.

First, the value of $\rho$ of 2.07 determined from Figure 3.4 is compatible with an $\mathrm{S}_{\mathrm{E}} 1$ mechanism. The positive value of $\rho$ confirms that negative charge is built up during H/D
exchange. The magnitude of $\rho$ is also suggestive of an $\mathrm{S}_{\mathrm{E}} 1$ mechanism; a large $\rho$ value means that a considerable amount of negative charge is built up during H/D exchange, which is more characteristic of an $\mathrm{S}_{\mathrm{E}} 1$ mechanism than of an $\mathrm{S}_{\mathrm{E}} 2$ mechanism.

Second, Hammett plots of the rate constants for general base-catalysed H/D exchange of 3a-h show a better correlation with $\sigma^{-}$constants than with standard $\sigma$ constants (Figure 3.4). This suggests that the negative charge is built up on the reaction centre during $\mathrm{H} / \mathrm{D}$ exchange, as it can be directly conjugated with the aromatic ring substituents. This location of charge is consistent with the $\mathrm{S}_{\mathrm{E}} 1$ mechanism, although it does not rule out an $\mathrm{S}_{\mathrm{E}} 2$ mechanism.

Third, CD and ${ }^{1} \mathrm{H}$ NMR analysis of the final, fully hydrolysed products of $\mathbf{3 a}$ and $\mathbf{3 e}$ show the proportion of material protonated at the stereogenic centre is almost equivalent with the enantiomeric excess. This observation rules out $\mathrm{H} / \mathrm{D}$ exchange by the $\mathrm{S}_{\mathrm{E}} 2$ mechanism.

### 3.4.9 Analysis of Thiophene Derivatives

As described in Section 3.3, $N$-acetyl thienylglycine methyl esters 3k and 31 (Scheme 3.10) were also synthesised for analysis of H/D exchange reactions.

3k

31

Scheme 3.10: Structure of compounds $\mathbf{3 k}$ and 31 .
Of specific interest is the possibility of incorporating heteroaromatic groups into the Hammett plots depicted in Figure 3.4. The application of the Hammett equation to heterocycles is discussed in Section 1.8.2.4. If it is shown that the kinetics of racemisation of compounds $\mathbf{3 k}$ and 31 can be accounted for by the Hammett analysis, it may then be possible to extend this relationship to predict the rate constants of H/D exchange for other heteroaromatic $N$-acetyl arylglycine methyl esters.

### 3.4.9.1 Kinetics of H/D Exchange for $3 k$ and 31

Reactions of compounds $\mathbf{3 k}$ and $\mathbf{3 1}$ in deuterated buffers were monitored via ${ }^{1} \mathrm{H}$ NMR spectroscopy. Rate constants of H/D exchange and hydrolysis were determined for 31.

Hydrolysis of 3k was negligible compared to H/D exchange ( $<4 \%$ ). Rate constants of H/D exchange were plotted as a function of basic buffer component (Figure 3.5).

Figure 3.5: Relationship between $k_{\text {deut }}$ and concentration of the basic buffer component for a) $\mathbf{3 k}$ b) $\mathbf{3 1}$. Experiments carried out at $37^{\circ} \mathrm{C}$ with $I=1 \mathrm{M}$.

Values for $k_{0}{ }^{\prime}, k_{\mathrm{gb}}$ and approximate half-lives of deuteration are collected in Table 3.7.
Table 3.7: $k_{\mathrm{gb}}$ and $k_{0}$ ' values for $\mathbf{3 k}$ and $\mathbf{3 1}$, approximate half-lives of deuteration at stereocentre of $\mathbf{3 k}-\mathbf{l}$ determined in $\mathrm{D}_{2} \mathrm{O} 0.3 \mathrm{M}$ phosphate buffers of $\mathrm{pH} * * 7.4, I=1 \mathrm{M}, 37^{\circ} \mathrm{C}$.

| Compound | $k_{\mathrm{gb}} / \mathbf{s}^{-1} \mathbf{M}^{-1}$ | $k_{0}{ }^{\prime} / \mathbf{s}^{-1}$ | $t_{1 / 2}$ of deuteration/h |
| :---: | :---: | :---: | :---: |
| 3k | $(2.74 \pm 0.10) \times 10^{-3}$ | $(-2.28 \pm 1.32) \times 10^{-5}$ | 0.4 |
| 31 | $(5.62 \pm 0.35) \times 10^{-5}$ | $(1.16 \pm 0.41) \times 10^{-6}$ | 16.5 |

As was the case for compounds $\mathbf{3 a - h}$, the values of $k_{0}{ }^{\prime}$ displayed in Table 3.7 show that specific base-catalysed or non-catalysed $\mathrm{H} / \mathrm{D}$ exchange of compounds $\mathbf{3 k}$ and $\mathbf{3 1}$ is negligible.

### 3.4.9.2 Hammett Analysis

Data for compounds $\mathbf{3 k}$ and $\mathbf{3 1}$ were added to the Hammett analysis displayed in Figure 3.4, using the $\sigma$-values displayed in Table 1.8 (Figure 3.6).

Figure 3．6：Hammett plots of data from Table 3.2 and Table 3.7 for general base－catalysed H／D exchange at the stereogenic centre of $\mathbf{3 a - h}$ and $\mathbf{3 k} \mathbf{k}$ ，in $\mathrm{D}_{2} \mathrm{O}$ phosphate buffers of $I=1 \mathrm{M}$ at $37^{\circ} \mathrm{C}$ ．a）as a function of $\sigma$－values（一） line of best fit for all data points，$\rho=2.70 \pm 0.02, \mathrm{R}^{2}=0.968$ ，（一）line of best fit for data points were $\sigma \geq 0, \rho=2.95 \pm 0.03, \mathrm{R}^{2}=0.980$ ．b）as a function of to $\sigma^{-}$－values（一）$\rho=2.35 \pm 0.02, \mathrm{R}^{2}=0.928$ ．

Figure 3.6 shows that the Hammett $\sigma$－constants for thiophene heterocycles displayed in Table 1.8 are in reasonable agreement with the experimental rate constants determined for compounds $\mathbf{3 k} \mathbf{k}$ ．The value of $k_{\mathrm{gb}}$ for $\mathbf{3 k}$ shows best correlation using $\sigma$－constants with electron withdrawing compounds only．The value of $k_{\mathrm{gb}}$ for 31 shows best correlation using $\sigma^{-}$－ constants．Although neither $k_{\mathrm{gb}}$ value for $\mathbf{3 k} \mathbf{k} \mathbf{l}$ fits exactly with the data obtained for compounds 3a－h，the general characterisation of a 2－thienyl heterocycle as a strongly electron－withdrawing substituent and 3－thienyl heterocycle as a moderately electron－ withdrawing substituent is supported by this data．The reasonable fit with Hammett plots for 3a－h suggests that H／D exchange for compounds $\mathbf{3 k} \mathbf{k}$ l also follows the $\mathrm{S}_{\mathrm{E}} 1$ mechanism proposed for 3a－h．

Using the $\sigma$－constants displayed in Table 1．8，we can extrapolate the Hammett plots to predict the susceptibility to racemisation of compounds containing other heterocycles．A compound based on the general scaffold displayed in Scheme 3.1 with a 2 －furyl aromatic substituent（ $\sigma=$ 1．08），would therefore be expected to undergo $\mathrm{H} / \mathrm{D}$ exchange at a rate faster than that seen for $\mathbf{3 k}$ ．Such a compound would therefore be at particular risk of racemisation under pharmacological conditions．Based on these $\sigma$－constants，a 3 －furyl substituted analogue would be expected to undergo $\mathrm{H} / \mathrm{D}$ exchange at a rate similar to that seen for $\mathbf{3 e}(p-\mathrm{Cl}$ substituted benzene）．Pyrrole－substituted analogues would be expected to undergo $\mathrm{H} / \mathrm{D}$ exchange at much slower rates，similar to that seen for $\mathbf{3 b}$（ $p-\mathrm{OH}$ substituted benzene）．A pyridine substituted analogue would be at a high risk of physiological racemisation．The $\mathrm{p} K_{\mathrm{a}}$ of pyridine is $5.23,{ }^{29}$
so the heteroatom would not be protonated at pH 7.4 . However, the $\sigma$-values in Table 1.8 still suggest that at this pH pyridine substituents are very electron-withdrawing ( $\sigma=0.45$ for 3pyridine, $\sigma=0.76$ for 4-pyridine) and would hence make racemisation a significant risk. Although rates of $\mathrm{H} / \mathrm{D}$ exchange have not been determined at $\mathrm{pH}<5.23$, conditions like this do of course exist in the body. The very high $\sigma$-value of a pyridine protonated at the heteroatom would be cause for concern even though general-base catalysis at low pH would be far weaker than under conditions investigated in this chapter.

### 3.5 Conclusions

Rate constants for H/D exchange and hydrolysis of compounds 3a-l have been determined under aqueous conditions in phosphate buffers at physiological pH and temperature. From this data the following conclusions can be drawn.

First, H/D exchange of 3a-l is general-base catalysed by the basic species of the phosphate buffer at $\mathrm{pH}^{* *} 7.4\left(\mathrm{HPO}_{4}{ }^{2-}\right)$.

Second, H/D exchange of 3a-l is of pharmacological relevance, particularly for those compounds with more electron-withdrawing aromatic groups.

Third, for compounds 3a and $\mathbf{3 e}$, studies suggest an $\mathrm{S}_{\mathrm{E}} 1$ mechanism for $\mathrm{H} / \mathrm{D}$ exchange and racemisation. Hammett correlations imply the same mechanism for 3b-d, f-l.

Fourth, results for 3k-I show that Hammett plots can be used to extend the scope of our results, allowing assessment of racemisation risks for other heterocyclic compounds.

### 3.6 Experimental

### 3.6.1 General Experimental

All reagents were purchased from Acros Organics, Alfa Aesar, Fluorochem or Sigma-Aldrich. ${ }^{1} H$ NMR and ${ }^{13} \mathrm{C}$ NMR spectra were recorded on a Bruker DPX 400 or DPX 500 spectrometer. $\delta$ values are reported in ppm downfield from trimethylsilane. HPLC was performed using an Agilent Technologies 1200 series instrument. Infrared spectra were obtained using a Varian 7000 FT-IR spectrometer. Samples were applied directly to the diamond tip. Circular Dichroism spectra were recorded using an Applied Photophysics Chirascan CD spectrometer. High-resolution mass spectra were obtained on a Waters LCT Premier XE mass spectrometer.

### 3.6.2 Synthesis of Compounds

### 3.6.2.1 Synthesis of Arylglycine Ester Hydrochloride Salts (2a-l)

Compounds 2a-l were synthesised from commercially available starting materials $\mathbf{1 a - h}, \mathbf{1 k}$ and $\mathbf{1 1}$ according to the method outlined by Kudelko and Zieliński (Scheme 3.11). ${ }^{30}$

Scheme 3.11: Synthesis of compounds 2a-I.
The general method outlined below in the synthesis of $\mathbf{2 a}$ was used in the synthesis of all compounds 2a-l, with the appropriate arylglycine starting material and alcohol used.

## Phenylglycine methyl ester hydrochloride (2a)

A suspension of phenylglycine ( $5 \mathrm{~g}, 33.1 \mathrm{mmol}$ ) in methanol ( 25 ml ) was cooled to $0^{\circ} \mathrm{C}$ and thionyl chloride ( $6.5 \mathrm{ml}, 3.97 \mathrm{~g}, 33.3 \mathrm{mmol}$ ) was added dropwise. The reaction mixture was allowed to warm to room temperature and left to stir overnight, then solvent was removed using a rotary evaporator. The crude product was washed with diethyl ether ( 30 ml ) and dried under reduced pressure to give phenylglycine methyl ester hydrochloride as a white solid ( $6.38 \mathrm{~g}, 31.7 \mathrm{mmol}, 96 \%$ ).
${ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{D}_{2} \mathrm{O}\right) \delta=7.32-7.39\left(\mathrm{~m}, 5 \mathrm{H},-\mathrm{C}_{6} \mathrm{H}_{5}\right), 5.15\left(\mathrm{~s}, 1 \mathrm{H},-\mathrm{CH}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)\right.$ ) ) $3.77(\mathrm{~s}$, $\left.3 \mathrm{H},-\mathrm{COOCH}_{3}\right)$.
${ }^{13} \mathrm{C}$ NMR $\left(100 \mathrm{MHz}, \mathrm{D}_{2} \mathrm{O}\right) \delta=169.90\left(1 \mathrm{C},-\mathrm{C}(\mathrm{O}) \mathrm{OCH}_{3}\right), 131.26$ (1C, aromatic), $130.76(1 \mathrm{C}$, aromatic), $130.01\left(2 \mathrm{C}\right.$, aromatics), $128.32\left(2 \mathrm{C}\right.$, aromatics), $56.68\left(1 \mathrm{C},-\mathrm{CHNH}_{3}{ }^{+}\right), 54.20(1 \mathrm{C}$, $-\mathrm{OCH}_{3}$ ).

### 3.6.2.2 Synthesis of N-Acetyl Arylglycine Esters (3a-I)

Compounds 3a-l were synthesised from compounds 2a-l according to the method outlined by Kudelko and Zieliński (Scheme 3.12). ${ }^{30}$

Scheme 3.12: Synthesis of compounds 3a-l.
The general method outlined below in the synthesis of 3a was used in synthesis of all compounds 3a-l.

## $N$-Acetyl phenylglycine methyl ester (3a)

Phenylglycine methyl ester hydrochloride ( $2 \mathrm{~g}, 9.9 \mathrm{mmol}$ ) was dissolved in cold water ( 20 $\mathrm{ml})$. Sodium hydrogen carbonate ( $2.13 \mathrm{~g}, 2.5$ equiv., 25 mmol ) was added and the mixture was stirred until carbon dioxide liberation was complete. Acetic anhydride ( $1 \mathrm{ml}, 10.5 \mathrm{mmol}$ ) was added dropwise and the mixture stirred for 1 hour. The solution was cooled to $0^{\circ} \mathrm{C}$ and the precipitate filtered off and recrystallised from isopropanol to give $N$-acetyl phenylglycine methyl ester as a white solid ( $1.67 \mathrm{~g}, 8.1 \mathrm{mmol}, 82 \%$ ).
${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{d}^{6}$-DMSO) $\delta=8.74\left(\mathrm{~d}, 1 \mathrm{H},-\mathrm{NH}-,{ }^{3} J_{\mathrm{H}-\mathrm{H}}=6.96 \mathrm{~Hz}\right.$ ), $7.34-7.39(\mathrm{~m}, 5 \mathrm{H},-$ $\left.\mathrm{C}_{6} \mathrm{H}_{5}\right), 5.39\left(\mathrm{~d}, 1 \mathrm{H},-\mathrm{CH}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)-,{ }^{3} J_{\mathrm{H}-\mathrm{H}}=7.12 \mathrm{~Hz}\right), 3.62\left(\mathrm{~s}, 3 \mathrm{H},-\mathrm{OCH}_{3}\right), 1.90(\mathrm{~s}, 3 \mathrm{H}$, $\mathrm{CH}_{3} \mathrm{C}(\mathrm{O})$-).
${ }^{13} \mathrm{C}$ NMR ( $\left.100 \mathrm{MHz}, \mathrm{d}^{6}-\mathrm{DMSO}\right) ~ \delta=171.57\left(1 \mathrm{C}, \mathrm{CH}_{3} \mathbf{C}(\mathrm{O})-\right.$ ), $169.68\left(1 \mathrm{C},-\mathbf{C}(\mathrm{O}) \mathrm{OCH}_{3}\right)$, 136.63 ( 1 C , aromatic), 129.07 ( 2 C , aromatics), 128.63 ( 1 C , aromatic), 128.15 (2C, aromatics), $56.63\left(1 \mathrm{C},-\mathrm{CH}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)-\right), 52.55\left(1 \mathrm{C},-\mathrm{OCH}_{3}\right), 22.50\left(1 \mathrm{C},-\mathrm{C}(\mathrm{O}) \mathrm{CH}_{3}\right)$.

### 3.6.2.3 Synthesis of N-Acetyl Phenylglycines (4a, c-e, i-h)

Compounds 4a, c-e, i-h were synthesised from compounds 1a, c-e, i-h according to the method outlined by de Boer et al. ${ }^{31}$

Scheme 3.13: Synthesis of compounds 4a, c-e, i-h.
The general method outlined below in the synthesis of $\mathbf{4 a}$ was used in synthesis of all compounds 4a, c-e, i-h.

## $N$-Acetyl phenylglycine (4a)

Phenylglycine ( $2 \mathrm{~g}, 13.2 \mathrm{mmol}$ ) was suspended in $\mathrm{H}_{2} \mathrm{O}(30 \mathrm{ml})$ and cooled to $0{ }^{\circ} \mathrm{C}$. Sodium hydroxide ( $0.53 \mathrm{~g}, 13.2 \mathrm{mmol}$ ) was added and the cooled solution stirred until all solid had dissolved. Acetic anhydride ( $2.5 \mathrm{ml}, 26.4 \mathrm{mmol}$ ) was added dropwise, followed by a solution of sodium hydroxide ( $1.59 \mathrm{~g}, 39.8 \mathrm{mmol}$ ) in $\mathrm{H}_{2} \mathrm{O}(8 \mathrm{ml})$ and the mixture was left to stir for 15 mins at $0^{\circ} \mathrm{C}$. The mixture was acidified to pH 1 using concentrated hydrochloric acid and the colourless precipitate formed was filtered off and washed on the filter with ice cold water. A portion was recrystallised from a $1: 1$ mixture of water and ethanol to give needle-like crystals ( $1.86 \mathrm{~g}, 9.6 \mathrm{mmol}, 73 \%$ ).
${ }^{1} \mathrm{H}$ NMR ( $\left.400 \mathrm{MHz}, \mathrm{d}^{6}-\mathrm{DMSO}\right) \delta=8.62\left(\mathrm{~d}, 1 \mathrm{H},-\mathrm{NH}-,{ }^{3} J_{\mathrm{H}-\mathrm{H}}=7.48 \mathrm{~Hz}\right), 7.32-7.39(\mathrm{~m}, 5 \mathrm{H},-$ $\left.\mathrm{C}_{6} \mathrm{H}_{5}\right), 5.31\left(\mathrm{~d}, 1 \mathrm{H},-\mathrm{CH}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)-{ }^{3} J_{\mathrm{H}-\mathrm{H}}=7.52 \mathrm{~Hz}\right), 1.89\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{CH}_{3} \mathrm{C}(\mathrm{O})-\right)$.
${ }^{13} \mathrm{C}$ NMR ( $\left.100 \mathrm{MHz}, \mathrm{d}^{6}-\mathrm{DMSO}\right) \delta=172.42\left(1 \mathrm{C}, \mathrm{CH}_{3} \mathbf{C O}-\right), 169.49\left(1 \mathrm{C},-\mathrm{COOCH}_{3}\right), 137.59$ $(1 \mathrm{C}$, aromatic), 128.89 ( 2 C , aromatics), 128.30 ( 1 C , aromatic), 128.03 ( 2 C , aromatics), 56.63 ( $1 \mathrm{C},-\mathbf{C H}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)$ ), $22.62\left(1 \mathrm{C},-\mathrm{C}(\mathrm{O}) \mathrm{CH}_{3}\right)$.

### 3.6.3 Proton-Deuterium Exchange Reactions Followed by ${ }^{1} \mathbf{H}$ NMR Spectroscopy

### 3.6.3.1 Experimental Procedure

Buffers for $\mathrm{H} / \mathrm{D}$ exchange experiments were prepared as follows. The appropriate quantity of $\mathrm{NaH}_{2} \mathrm{PO}_{4}$ for the desired buffer concentration was dissolved in $\mathrm{D}_{2} \mathrm{O}$. The ionic strength was made to 1 M using NaCl . The desired $\mathrm{pH}^{* *}$ was obtained through adding portions of $\mathrm{NaOD} / \mathrm{D}_{2} \mathrm{O}$ solution whilst monitoring the pH .

H/D exchange experiments were carried out as follows. 1 ml solutions of approximately 0.005 M concentration of the compound for analysis in the appropriate buffer solution were prepared in Eppendorf vials. The vial was vortexed to aid dissolution, and the contents filtered to ensure no solid remained. The resulting solution was then placed in a sealed NMR tube which was maintained at $37^{\circ} \mathrm{C}$ using a thermostatted water bath. The tube was removed from the water bath at intervals as required for analysis by ${ }^{1} \mathrm{H}$ NMR spectroscopy, then returned to the water bath. The hydrolysis reaction of compounds 3a-l produces the carboxylic acid, which lowers the $\mathrm{pH}^{* *}$. As a result, the $\mathrm{pH}^{* *}$ of the reaction mixture was monitored using a micro pH meter and maintained at the desired $\mathrm{pH}^{* *} \pm 0.05$ by addition of aliquots of a 0.01 M $\mathrm{NaOD} / \mathrm{D}_{2} \mathrm{O}$ solution as required. Initial experiments showed that $\mathrm{H} / \mathrm{D}$ exchange and hydrolysis reactions obeyed pseudo-first-order rate law and hence rate constants are independent of initial concentration.

Compound $\mathbf{3 k}$ underwent $\mathrm{H} / \mathrm{D}$ exchange too rapidly to adequately monitor the reaction through the previously described method. As such, the compound was dissolved in the appropriate buffer in an NMR tube as described previously, and the NMR tube was placed in the probe of the NMR spectrometer, which was maintained at $37^{\circ} \mathrm{C}$ and spectra were recorded every 15 minutes. As hydrolysis rates for $\mathbf{3 k}$ were small in respect to $\mathrm{H} / \mathrm{D}$ exchange, $\mathrm{pH}^{* *}$ adjustments were not required.

### 3.6.3.2 Interpretation of ${ }^{1} H$ NMR Spectra

Spinworks 2.5 .5 was used to analyse ${ }^{1} \mathrm{H}$ NMR spectra. The analysis in this chapter was based on the integration of the peaks corresponding to the protons bound to the stereogenic centre in
compounds $\mathbf{3 a - l}$ and $\mathbf{4 a - h}, \mathbf{k}-\mathbf{l}$. The integration of these peaks was relative to the peaks for the aromatic protons. The data was 'normalised' according to the number of aromatic protons. For example, when analysing compounds $\mathbf{3 a}, \mathbf{i} \mathbf{j}$, the integrations of the stereogenic-centre-bound proton relative to the aromatic protons were multiplied by five, as $\mathbf{3 a}$ has five aromatic protons. For compounds $\mathbf{3 c} \mathbf{c h}$, the signal was multiplied by four. As the two aromatic peaks in compound 3b have rather different chemical shifts ( $\sim 0.4 \mathrm{ppm}$ ), it was decided to base the integration on only the farthest upfield peak ( 7.17 ppm ) to avoid errors resulting from integrating over large stretches of baseline. As such the signal was normalised by a factor of two. Integrals for $\mathbf{3 k}$ were normalised based on the aromatic thiophene peak at 7.53 ppm . Integrals for 31 were normalised based on the aromatic thiophene peak at 7.12 ppm .

### 3.6.3.3 Interpretation of Data

The analysis of the data for compound $\mathbf{3 a}$ in deuterated buffer shall be used as an example to illustrate the method by which the data was interpreted for all compounds 3a-l.

The relative peak integration corresponding to the proton bound to the stereogenic centre for both 3a and 4a can be used to calculate the proportion of molecules which have been deuterated at the stereogenic centre. This value can be obtained by subtracting the relative intensity of both from the initial relative intensity of the protons bound to the stereogenic centre (eqn 3.5).

$$
\begin{equation*}
\left[\mathbf{3} \mathbf{a}^{\mathrm{D}}\right]+\left[\mathbf{4} \mathbf{a}^{\mathrm{D}}\right]=\left[\mathbf{3} \mathbf{a}^{\mathrm{H}}\right]_{0}-\left\{\left[\mathbf{3} \mathbf{a}^{\mathrm{H}}\right]+\left[\mathbf{4} \mathbf{a}^{\mathrm{H}}\right]\right\} \tag{3.5}
\end{equation*}
$$

where $\left[3 a^{D}\right]$ is the concentration of $\mathbf{3 a}$ with a deuteron bound to the stereogenic centre, $\left[4 \mathbf{a}^{\mathrm{D}}\right.$ ] is the concentration of $\mathbf{4 a}$ with a deuteron bound to the stereogenic centre, $\left[\mathbf{3 a}{ }^{\mathrm{H}}\right]$ is the concentration of $\mathbf{3 a}$ with a proton bound to the stereogenic centre, $\left[\mathbf{4} \mathbf{a}^{\mathrm{H}}\right]$ is the concentration of $4 \mathbf{a}$ with a proton bound to the stereogenic centre and $\left[3 \mathbf{a}^{H}\right]_{0}$ is the starting concentration of 3a with a proton bound to the stereogenic centre.
$\left[\mathbf{3} \mathbf{a}^{\mathrm{H}}\right],\left[\mathbf{4} \mathbf{a}^{\mathrm{H}}\right]$ and $\left\{\left[\mathbf{3} \mathbf{a}^{\mathrm{D}}\right]+\left[\mathbf{4 \mathbf { a } ^ { \mathrm { D } }}\right]\right\}$ were plotted as a function of time (Figure 3.7).

Figure 3.7: Relative integration of ( $\left(\mathbf{)}\left[\mathbf{3} \mathbf{a}^{\mathrm{H}}\right],(\bullet)\left[4 \mathrm{a}^{\mathrm{H}}\right]\right.$ and $(\mathbf{\Delta})\left\{\left[3 \mathbf{a}^{\mathrm{D}}\right]+\right.$ $\left.\left[4 \mathbf{a}^{\mathrm{D}}\right]\right\}$ as a function of time in $0.2 \mathrm{M} \mathrm{D}_{2} \mathrm{O}$ phosphate buffer, $I=1 \mathrm{M}$, at 37 ${ }^{\circ} \mathrm{C}$.

First-order rate constants were obtained by data analysis according to eqn (3.6).

$$
\begin{equation*}
S_{t}=S_{\mathrm{f}}-\left(\Delta S \times \mathrm{e}^{(-k x)}\right) \tag{3.6}
\end{equation*}
$$

where $S_{t}$ is the relative peak intensity at time $t, S_{\mathrm{f}}$ is the final peak intensity, $\Delta S$ is the change in peak intensity, $k$ is the observed first-order rate constant and $t$ is the elapsed time in seconds.

This data was plotted using OriginPro 8, and analysed using the 'global fit' function. All three curves in Figure 3.7 were defined to fit to the same observed rate constant. This observed rate constant is the sum of the rate constants of $\mathrm{H} / \mathrm{D}$ exchange and of hydrolysis (eqn 3.7).

$$
\begin{equation*}
k_{\mathrm{obs}}=k_{\mathrm{deut}}+k_{\mathrm{hyd}} \tag{3.7}
\end{equation*}
$$

where $k_{\text {obs }}$ is the observed rate constant for disappearance of $\mathbf{3} \mathrm{a}^{\mathrm{H}}, k_{\text {deut }}$ is the rate constant of $\mathrm{H} / \mathrm{D}$ exchange and $k_{\mathrm{hyd}}$ is the rate constant of hydrolysis.

The concentration of $\mathbf{3} \mathrm{a}^{\mathrm{H}}$ decreases by both $\mathrm{H} / \mathrm{D}$ exchange and hydrolysis. Therefore, the rate constant for the disappearance of $\mathbf{3 a}{ }^{H}$ is the sum of the rate constants for both $H / D$ exchange and hydrolysis reactions. The formation of both $4 a^{H}$ and $\left\{3 a^{D}+4 a^{D}\right\}$ is dependent on the concentration of $3 \mathbf{a}^{\mathrm{H}}$, as it is the starting material for both. Therefore, the observed rate constants of formation for $\mathbf{4} \mathbf{a}^{\mathrm{H}}$ and $\left\{\mathbf{3} \mathbf{a}^{\mathrm{D}}+\mathbf{4} \mathbf{a}^{\mathrm{D}}\right\}$ are the same as that for disappearance of $\mathbf{3} \mathbf{a}^{\mathrm{H}}$. The individual rate constants for the H/D exchange and hydrolysis reactions can then be determined from the relative final amounts of $\mathbf{4} \mathbf{a}^{H}$ and $\left\{3 \mathbf{a}^{\mathrm{D}}+\mathbf{4 a}^{\mathrm{D}}\right\}$. The ratio of these products will be equal to the ratio of the relative rate constants $k_{\text {deut }}$ and $k_{\text {hyd }}$ (eqn 3.8).

$$
\begin{equation*}
\frac{k_{\text {deut }}}{k_{\mathrm{hyd}}}=\frac{S_{\mathrm{f}(\mathrm{deut})}}{S_{\mathrm{f}(\mathrm{hyd})}} \tag{3.8}
\end{equation*}
$$

Where $S_{\mathrm{f} \text { (deut) }}$ is the final proportion of compound deuterated at the stereogenic centre and $S_{\mathrm{f}}$ ${ }_{(\text {(hyd) })}$ is the final proportion of carboxylate protonated at the stereogenic centre.

Eqns (3.7) and (3.8) can then be combined, allowing $k_{\text {hyd }}$ to be determined from the observed rate constant (eqn 3.9).

$$
k_{\text {deut }}=\frac{S_{\mathrm{f}(\mathrm{deutl})}}{S_{\mathrm{f}(\mathrm{hyd})}} \cdot k_{\mathrm{hyd}}
$$

therefore,

$$
\begin{align*}
& k_{\mathrm{obs}}=\frac{S_{\mathrm{f}(\mathrm{deut})}}{S_{\mathrm{f}(\mathrm{hyd})}} \cdot k_{\mathrm{hyd}}+k_{\mathrm{hyd}} \\
& k_{\mathrm{obs}}=k_{\mathrm{hyd}}\left\{\frac{S_{\mathrm{f}(\mathrm{deut})}}{S_{\mathrm{f} \text { (hyd) })}}+1\right\} \tag{3.9}
\end{align*}
$$

$k_{\text {deut }}$ is then determined by substituting $k_{\text {hyd }}$ back into eqn (3.7).

### 3.6.4 Determination of Enantiomeric Excess

As described in Section 3.4.8.1, Circular Dichroism spectroscopy was used to determine the $e e_{f}$ of compounds $4 \mathbf{a}$ and 4 e after hydrolysis of $\mathbf{3 a}$ and $\mathbf{3 e}$. Comparison of $e e_{f}$ with $Q_{\mathrm{f}}{ }^{\mathrm{H}}$ allowed the determination of the mechanism of $\mathrm{H} / \mathrm{D}$ exchange. The $e e_{\mathrm{f}}$ was determined via the method described by Reetz et al. ${ }^{32}$ Normalisation of the circular dichroism with respect to UV absorbance gives the anisotropy factor, also known as the $g$ factor (eqn 3.10)

$$
\begin{equation*}
g=\frac{\theta}{A} \tag{3.10}
\end{equation*}
$$

where $g$ is the anisotropy factor, $\theta$ is the ellipticity and $A$ is the UV absorbance.
If the $g$ factor can be shown to be independent of concentration and linear with respect to the $e e$, the ee of a solution of unknown concentration can be determined. Calibration curves for the $g$ factor of $\mathbf{4 a}$ and $\mathbf{4 e}$ can be found in the Appendix (Section 3.7.2).

The ee of compounds $\mathbf{4 a}$ and $\mathbf{4 e}$ after full hydrolysis from enantiopure $\mathbf{3 a}$ and $\mathbf{3 e}$ starting materials $\left(e e_{\mathrm{f}}\right)$ was determined as follows.

A stock solution was made of $0.026 \mathrm{~g}(R)-(-)-\mathbf{3 a}$ in 20 ml of $\mathrm{D}_{2} \mathrm{O}$ buffer of $\mathrm{pH}^{* *} 7.4,0.3 \mathrm{M}$ phosphate concentration and $I=1 \mathrm{M}(6.28 \mathrm{mM}$ in 3a). The solution was incubated in a water
bath at $37{ }^{\circ} \mathrm{C}$. Intermittently, a 0.5 ml portion was removed and analysed through ${ }^{1} \mathrm{H}$ NMR, to monitor hydrolysis. $\mathrm{pH}^{* *} 7.4 \pm 0.05$ was maintained through addition of aliquots of a 0.01 M $\mathrm{NaOD} / \mathrm{D}_{2} \mathrm{O}$ solution as required. After 350 hrs , the ${ }^{1} \mathrm{H}$ NMR spectrum suggested no 3a remained in solution (disappearance of peak corresponding to methyl ester protons). To ensure full hydrolysis, the solution was kept incubated for a further 150 hrs . HPLC analysis (see Section 3.6.5) confirmed that no 3a remained in solution. The solution was then analysed using CD spectroscopy. The $g$ factor was determined for the fully hydrolysed solution, at 6 concentrations between 0.123 and 0.355 mM (dilution with $\mathrm{H}_{2} \mathrm{O}$ ). The $g$ factor was found to be $-40.391 \pm 1.828$, corresponding to $e e_{\mathrm{f}}=-45.499 \pm 2.133$ (from Figure 3.10).

The experiment for hydrolysis of $\mathbf{3 e}$ to $\mathbf{4 e}$ was carried out in an analogous fashion. The original stock solution used was $0.010 \mathrm{~g}(S)-(+)-3 \mathbf{e}$ in 20 ml of $\mathrm{D}_{2} \mathrm{O}$ buffer of $\mathrm{pH}^{* *} 7.4,0.3 \mathrm{M}$ phosphate concentration and $I=1 \mathrm{M}(2.07 \mathrm{mM}$ in 3 e$)$. After 60 hrs incubation at $37^{\circ} \mathrm{C}$ the ${ }^{1} \mathrm{H}$ NMR spectrum suggested no 3 e remained in solution. The solution was incubated for a further 150 hrs before CD spectroscopy was used to determine the $g$ factor at 223 nm for 6 different concentrations between 0.058 and 0.141 mM (dilution with $\mathrm{H}_{2} \mathrm{O}$ ). The average $g$ factor was found to be $15.856 \pm 0.732$, corresponding to $e e_{\mathrm{f}}=+30.166 \pm 1.387$ (from Figure 3.12).

### 3.6.5 HPLC

Reverse-phase HPLC was used to confirm $k_{\text {hyd }}$ as determined by ${ }^{1} \mathrm{H}$ NMR spectroscopy. Experiments were carried out using an Eclipse column (XD8-C18, $5 \mu \mathrm{~m}, 4.6 \times 150 \mathrm{~mm}$ ). A method to separate ester $\mathbf{3 a}$ from hydrolysis product $\mathbf{4 a}$ was developed. Flow rate was 1 ml / minute and UV detection of products was at 260 nm with 40 nm bandwidth. The eluents and the gradient used in the LC method are as follows:

Channel $\mathrm{A}=\mathrm{H}_{2} \mathrm{O}$, Channel $\mathrm{B}=\mathrm{CH}_{3} \mathrm{CN}$, Channel $\mathrm{C}=0.02 \%$ TFA in $\mathrm{H}_{2} \mathrm{O}(\mathrm{pH} 1.67)$.
Table 3.8: Gradient used for HPLC experiments.

| Time (mins) |  | $\% \mathrm{~A}$ |  | $\% \mathrm{~B}$ | $\% \mathrm{C}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | 90 |  | 0 | 10 |
| 4.0 |  |  | 0 |  | 40 |
| 7.0 |  |  |  | 10 |  |
| 9.0 |  |  | 40 | 10 |  |

Carboxylic acid 4a eluted between 5-5.25 minutes, ester 3a eluted between 6.15-6.3 minutes. HPLC calibration curves for $\mathbf{3 a}$ and $\mathbf{4 a}$ can be found in the Appendix (Section 3.7.3).
$k_{\text {hyd }}$ of 3 a in $\mathrm{D}_{2} \mathrm{O}$ buffer of $\mathrm{pH}^{* *} 7.4$, phosphate concentration $0.2 \mathrm{M}, I=1 \mathrm{M}$ was determined according to the following method.
0.013 g of $\mathbf{3 a}$ was dissolved in 10 ml of $\mathrm{D}_{2} \mathrm{O}$ buffer. The sample tube was incubated at $37^{\circ} \mathrm{C}$. $\mathrm{pH}^{* *} 7.4 \pm 0.05$ was maintained through addition of small portions of $0.01 \mathrm{M} \mathrm{NaOD} / \mathrm{D}_{2} \mathrm{O}$ solution as required. Intermittently, a 0.5 ml portion of this stock solution was withdrawn and placed in a HPLC vial. A $10 \mu \mathrm{l}$ injection from this vial was made into the HPLC instrument and the previously described HPLC method run. The remaining material was returned to the stock solution for further injections to be made. Results of the HPLC run were compared with the calibration curves to determine the quantity of each species. These results are displayed in Figure 3.8.

Figure 3.8: Change in quantity of $(\bullet) \mathbf{3 a}$ and ( $\mathbf{\bullet}) \mathbf{4 a}$ in $10 \mu \mathrm{l}$ injections over time.

Each curve produced the same rate constant of $(2.14 \pm 0.05) \times 10^{-6} \mathrm{~s}^{-1}$. This compares favourably with the $k_{\text {hyd }}$ value determined under the same conditions through ${ }^{1} \mathrm{H}$ NMR spectroscopy.

### 3.6.6 Miscellaneous

The data presented in Figure 3.9 (Appendix Section 3.7.1.2) was modelled numerically using Microsoft Excel 2010. Calculations modelled the kinetic scheme shown in Scheme 3.15. Initial concentrations were set at 100 for $(R)-\mathbf{3 a}^{\mathrm{H}}$ and 0 for all other species. The concentration of each species is displayed in eqns (3.11)-(3.16), where [ $]_{\mathrm{pt}}$ refers to the concentration of the denoted species at the previous time point, $k_{\text {inv }}$ is the rate constant for
proton deuterium exchange at the stereogenic centre with chiral inversion, $k_{\text {hyd }}$ is the rate constant of hydrolysis, KIE is the kinetic isotope effect on $k_{\text {inv }}$ and $\mathrm{d} t$ refers to the time step since the previous time point.
$\left[(R)-\mathbf{3 a}^{\mathrm{H}}\right]=\left[(R)-\mathbf{3 a}^{\mathrm{H}}\right]_{\mathrm{pt}} \cdot\left\{1-\left(k_{\mathrm{inv}}+k_{\mathrm{hyd}}\right) \cdot \mathrm{d} t\right\}$
$\left[(S)-\mathbf{3 a}^{\mathrm{D}}\right]=\left[(S)-\mathbf{3 a}^{\mathrm{D}}\right]_{\mathrm{pt}} \cdot\left\{1-\left(k_{\mathrm{hyd}}+\left(k_{\mathrm{inv}} / \mathrm{KIE}\right)\right) \cdot \mathrm{d} t\right\}+\left[(R)-\mathbf{3 a}^{\mathrm{H}}\right]_{\mathrm{pt}} \cdot k_{\mathrm{inv}} \cdot \mathrm{d} t$

$$
\begin{equation*}
+\left[(R)-\mathbf{3 a}^{\mathrm{D}}\right]_{\mathrm{pt}} \cdot\left(k_{\text {inv }} / \mathrm{KIE}\right) \cdot \mathrm{d} t \tag{3.12}
\end{equation*}
$$

$\left[(R)-\mathbf{3 a}^{\mathrm{D}}\right]=\left[(R)-\mathbf{3 a}^{\mathrm{D}}\right]_{\mathrm{pt}} \cdot\left\{1-\left(k_{\mathrm{hyd}}+\left(k_{\text {inv }} / \mathrm{KIE}\right)\right) \cdot \mathrm{d} t\right\}+\left[(S)-\mathbf{3 a}^{\mathrm{D}}\right]_{\mathrm{pt}} \cdot\left(k_{\text {inv }} / \mathrm{KIE}\right) \cdot \mathrm{d} t$
$\left[(R)-\mathbf{4 a}^{\mathrm{H}}\right]=\left[(R)-\mathbf{3 a}^{\mathrm{H}}\right]_{\mathrm{pt}} \cdot \boldsymbol{k}_{\mathrm{hyd}} \cdot \mathrm{d} t$
$\left[(S)-\mathbf{4 a}{ }^{\mathrm{D}}\right]=\left[(S)-\mathbf{3 a}{ }^{\mathrm{D}}\right]_{\mathrm{pt}} \cdot k_{\mathrm{hyd}} \cdot \mathrm{d} t$
$\left[(R)-\mathbf{4 a}^{\mathrm{D}}\right]=\left[(R)-\mathbf{3 a}^{\mathrm{D}}\right]_{\mathrm{pt}} \cdot \boldsymbol{k}_{\mathrm{hyd}} \cdot \mathrm{d} t$
$k_{\text {inv }}, k_{\text {hyd }}$ and KIE are all variables, and the time step $\mathrm{d} t$ was chosen to be as short as practically possible. Modification of $k_{\text {inv }}, k_{\text {hyd }}$ and KIE produced the different values for $Q_{\mathrm{f}}{ }^{\mathrm{H}}$ and $e e_{\mathrm{f}}$ shown in Table 3.9.

### 3.7 Appendix

### 3.7.1 Theoretical Background for Equations 3.3 and 3.4

### 3.7.1.1 $S_{E} 1$ Mechanism (Eqn 3.3)

If the experiments outlined in Section 3.4.1 are undertaken with a chiral starting material, $(R)$ 3a, and $\mathrm{H} / \mathrm{D}$ exchange proceeds through the $\mathrm{S}_{\mathrm{E}} 1$ mechanism, the reaction profile shown in Scheme 3.8 is altered to that shown in Scheme 3.14.

$(R)-\mathbf{4} \mathbf{a}^{\mathrm{H}}$

Scheme 3.14: Reaction scheme of $(R)$-3a in deuterated buffers, if mechanism of $\mathrm{H} / \mathrm{D}$ exchange/racemisation is $\mathrm{S}_{\mathrm{E}} 1$.

Because the carbanion intermediate formed from deprotonation of $(R)$-3a can be deuterated on either face, the portion of the final, fully hydrolysed product $\mathbf{4 a}$ which is deuterated at the stereogenic centre will also be racemic. The portion of final product $\mathbf{4 a}$ which is protonated at the stereogenic centre will be enantiopure; once hydrolysis has occurred no H/D exchange or racemisation will take place due to the negative charge on the carboxylate. Therefore, if the ee of $\mathbf{4 a}$ (after hydrolysis is complete) is equal to the percentage of $\mathbf{4 a}$ which is protonated at the stereogenic centre, the data is consistent with an $\mathrm{S}_{\mathrm{E}} 1$ mechanism (eqn 3.3).

$$
\begin{equation*}
Q_{\mathrm{f}}{ }^{\mathrm{H}}=e e_{\mathrm{f}} \tag{3.3}
\end{equation*}
$$

where $Q_{f}{ }^{H}$ is the percentage of $4 \mathbf{a}$ molecules protonated at the stereogenic centre after hydrolysis is complete and $e e_{\mathrm{f}}$ is the enantiomeric excess of $\mathbf{4 a}$ after hydrolysis is complete.

### 3.7.1.2 $S_{E} 2$ Mechanism (Eqn 3.4)

If $\mathrm{H} / \mathrm{D}$ exchange/racemisation of $(R)$-3a proceeds via the $\mathrm{S}_{\mathrm{E}} 2$ mechanism, the reaction scheme will be as depicted in Scheme 3.15.

$(R)-\mathbf{4} \mathbf{a}^{\mathrm{H}}$
$(S)-4 \mathbf{a}^{\mathrm{D}}$
$(R)-4 \mathbf{a}^{\mathrm{D}}$
Scheme 3.15: Reaction scheme of ( $R$ )-3a in deuterated buffers, if mechanism of $\mathrm{H} / \mathrm{D}$ exchange/racemisation is $\mathrm{S}_{\mathrm{E}} 2 . k_{\text {inv }}$ is the rate constant of $\mathrm{H} / \mathrm{D}$ exchange at stereogenic centre with chiral inversion. KIE is the primary kinetic isotope effect on $k_{\text {inv }}$ as a result of deuteration on the stereogenic centre. Secondary kinetic isotope effects on $k_{\text {hyd }}$ due to deuteration on the stereogenic centre were considered negligible.

A kinetic analysis of how the concentrations of each species shown in Scheme 3.15 changes with time if an $\mathrm{S}_{\mathrm{E}} 2$ mechanism is occurring is displayed in Figure 3.9.

Figure 3.9: Kinetic profile for reaction scheme displayed in Scheme 3.15, where $(■)(R)-\mathbf{3 a}^{\mathrm{H}},(\bullet)(S)-\mathbf{3} \mathbf{a}^{\mathrm{D}},(\boldsymbol{\Delta})(R)-\mathbf{3} \mathbf{a}^{\mathrm{D}},(\mathbf{\nabla})(R)-\mathbf{4} \mathbf{a}^{\mathrm{H}},(\boldsymbol{4})(S)-\mathbf{4} \mathbf{a}^{\mathrm{D}}$, $(>)(R)-4 a^{\mathrm{D}}$. The time units in Figure 3.9 are arbitrary. The ratio of $k_{\text {inv: }} k_{\text {hyd }}$ is set to $1: 0.7,,^{* *}$ and the kinetic isotope effect on $k_{\text {inv }}$ of a deuterated stereogenic centre set to 2.5 . Details of the construction of this plot are provided in the experimental (Section 3.6.6).

Figure 3.9 can be used to predict what would be the expected ratio of final ee to the proportion of molecules protonated at the stereogenic centre for the fully hydrolysed product 4a. The only final product protonated at the stereogenic centre is $(R)-4 \mathbf{a}^{H}(\nabla$ in Figure 3.9). Therefore, the proportion of molecules deuterated at the stereogenic centre for the fully hydrolysed product $\mathbf{4 a}$, is equal to the proportion of $(R)-4 \mathbf{a}^{\mathrm{H}}$ in the reaction mixture after the reaction is complete (i.e. the proportion of molecules that undergo hydrolysis before H/D deuteration). This is the same as previously described for the $\mathrm{S}_{\mathrm{E}} 1$ mechanism. However, because the $\mathrm{S}_{\mathrm{E}} 2$ mechanism deuterates with chiral inversion, the $\mathbf{3 a}{ }^{\mathrm{D}}$ molecules formed from the starting material will be of ( $S$ ) stereochemistry (unlike the racemate formed from $\mathrm{S}_{\mathrm{E}} 1$ mechanism). This means that a far higher proportion of the final $\mathbf{4 a}$ product is of ( $S$ ) stereochemistry and the ee will be lower than the proportion of protonated final product. Eqns (3.17)-(3.19) illustrate this for the $\mathrm{S}_{\mathrm{E}} 2$ mechanism.

$$
\begin{align*}
& Q_{\mathrm{f}}{ }^{\mathrm{H}}=\left[(R)-\mathbf{4 \mathbf { a } ^ { \mathrm { H } }}\right]  \tag{3.17}\\
& \left.e e_{\mathrm{f}}=\left[(R)-\mathbf{4} \mathbf{a}^{\mathrm{H}}\right]-\left\{(S)-\mathbf{4 \mathbf { a } ^ { \mathrm { D } }}\right]-\left[(R)-\mathbf{4 \mathbf { a } ^ { \mathrm { D } }}\right]\right\} \tag{3.18}
\end{align*}
$$

[^13]\[

$$
\begin{equation*}
\left.e e_{\mathbf{f}}=Q_{\mathbf{f}}^{\mathbf{H}}-\left\{(S)-4 \mathbf{a}^{\mathbf{D}}\right]-\left[(R)-4 \mathbf{a}^{\mathbf{D}}\right]\right\} \tag{3.19}
\end{equation*}
$$

\]

Eqns (3.17)-(3.19) show that, as the molecules of $\mathbf{4 a}$ deuterated on the stereogenic centre will have a higher proportion of $(S)$ than $(R)$ configuration, the value for $Q_{\mathrm{f}}{ }^{\mathrm{H}}$ will be higher than $e e_{\mathrm{f}}$ if an $\mathrm{S}_{\mathrm{E}} 2$ mechanism is occurring. The ratio of $k_{\mathrm{inv}}$ to $k_{\text {hyd }}$ and the KIE used in formulation of Figure 3.9 would give $Q_{\mathrm{f}}^{\mathrm{H}}=41 \%$ and $e e_{\mathrm{f}}=14 \%$.

Using different ratios of $k_{\text {inv }}$ to $k_{\text {hyd }}$ and a different KIE will alter the ratio of $Q_{\mathrm{f}}{ }^{\mathrm{H}}$ to $e e_{\mathrm{f}}$. However, $Q_{\mathrm{f}}^{\mathrm{H}}$ will always be greater than $e e_{\mathrm{f}}$ for an $\mathrm{S}_{\mathrm{E}} 2$ mechanism except in cases where $k_{\text {inv }}$ is far greater than $k_{\text {hyd }}$. In circumstances where $k_{\text {inv }} \gg k_{\text {hyd }}$, deuterated 3a will equilibrate before any can be 'siphoned-off' by hydrolysis resulting in $Q_{\mathrm{f}}{ }^{\mathrm{H}}=e e_{\mathrm{f}}$. The relationship between $Q_{\mathrm{f}}{ }^{\mathrm{H}}$ and $e e_{\mathrm{f}}$ for the $\mathrm{S}_{\mathrm{E}} 2$ mechanism is therefore described by eqn (3.4).

$$
\begin{equation*}
Q_{\mathrm{f}}{ }^{\mathrm{H}}>e e_{\mathrm{f}} \tag{3.4}
\end{equation*}
$$

except where $k_{\text {inv }} \gg k_{\text {hyd }}$.
Values of $Q_{\mathrm{f}}{ }^{\mathrm{H}}$ and $e e_{\mathrm{f}}$ for scenarios of different $k_{\mathrm{inv}}, k_{\text {hyd }}$ and KIE are displayed in Table 3.9.
Table 3.9: Expected values of $Q_{\mathrm{f}}{ }^{\mathrm{H}}$ and $e e_{\mathrm{f}}$ based on values of $k_{\text {inv }}, k_{\text {hyd }}$ and KIE, if an $\mathrm{S}_{\mathrm{E}} 2$ mechanism of racemisation is taking place.

| Input |  |  | Output |  |
| :---: | :---: | :---: | :---: | :---: |
| $\boldsymbol{k}_{\text {inv }}$ | $\boldsymbol{k}_{\text {hyd }}$ | KIE | $Q_{f}{ }^{\text {H }}$ | $e e_{\text {f }}$ |
| 1 | 0.7 | 2.5 | 41 \% | 14 \% |
| 1 | 1.5 | 2.5 | 60 \% | 34 \% |
| 1 | 0.7 | 1 | $41 \%$ | 26 \% |
| 1 | 1.5 | 1 | 60 \% | 43 \% |
| 1 | 5 | 2.5 | 83 \% | 69 \% |
| 1 | 0.01 | 2.5 | $1 \%$ | $0 \%$ |

### 3.7.2 Circular Dichroism Calibrations

### 3.7.2.1 CD Calibration for the ee Determination of $4 a$

To calibrate for determination of $e e$ of solutions of $\mathbf{4 a}, 0.163 \mathrm{mM}$ solutions of $\mathbf{4 a}$ in water were made with ee $(+)-100,(+)-80,(+)-40,(+)-20,0,(-)-20,(-)-40,(-)-80$ and $(-)-100$. The absorbance and circular dichroism were determined at 217 nm for each solution, using a 1 cm pathlength cuvette. After baseline subtraction, these values were used to determine the $g$ factor for each solution (Figure 3.10).

Figure 3.10: Calibration graph of $g$ factor against $e e$ for 4 a, determined at 217 nm for 0.163 mM solutions. Gradient $=0.857 \pm 0.006$, intercept $=-1.399 \pm 0.378 . \mathrm{R}^{2}=0.9996$.

It was necessary to confirm that the $g$ factor is independent of concentration for $\mathbf{4 a}$. The $g$ factor was determined for solutions of $\mathbf{4 a}$ for a range of concentrations between 0.033 and 0.319 mM , all with $e e=(-)-40$ (Figure 3.11$)$.

Figure 3.11: Dependency of the $g$ factor at 217 nm on concentration for $\mathbf{4 a}$ solutions with $e e=(-)-40$, standard deviation $=2.45 \%$.

Figure 3.11 clearly shows that the $g$ factor for $\mathbf{4 a}$ is independent of concentration.

### 3.7.2.2 CD Calibration for the ee Determination of $4 e$

The ee determination for $\mathbf{4 e}$ was calibrated in the same manner as for $\mathbf{4 a}$. Absorbance and circular dichroism were determined at 223 nm . As only $(S)-(+)-4 \mathbf{e}$ was available, the $g$ factor was only determined for ( + )-ee values (Figure 3.12)

Figure 3.12: Calibration graph of $g$ factor against $e e$ for $\mathbf{4 e}$, determined at 223 nm for 0.086 mM solutions. Gradient $=0.528 \pm 0.012$, intercept $=-$ $0.072 \pm 0.743 . \mathrm{R}^{2}=0.997$.

The $g$ factor was determined for solutions of $\mathbf{4 e}$ at a range of concentrations between 0.052 and 0.185 mM , all with $e e=(+)-40$ (Figure 3.13).

Figure 3.13: Dependency of $g$ factor at 223 nm on concentration for $\mathbf{4 e}$ solutions with $e e=(-)-40$, standard deviation $=2.62 \%$.

Figure 3.13 clearly shows that the $g$ factor of $\mathbf{4 e}$ is independent of concentration.

### 3.7.3 HPLC Calibrations for 3a and 4a

Solutions of 4 and $2 \mathrm{gL}^{-1}$ of $\mathbf{3 a}$ and $\mathbf{4 a}$ were made up. Each solution was then diluted by $1 / 4,1 / 2$, and $3 / 4$. HPLC calibration graphs were obtained using 5 and $10 \mu \mathrm{l}$ injections of each solution (Figure 3.14 and Figure 3.15).

Figure 3.14: HPLC calibration for 3a. Gradient $=(5.46 \pm 0.05) \times 10^{9}$, intercept $=11.28 \pm 3.87 . \mathrm{R}^{2}=0.999$.

Figure 3.15: HPLC calibration of $\mathbf{4 a}$. Gradient $=(5.64 \pm 0.07) \times 10^{9}$, intercept $=15.94 \pm 6.22 . \mathrm{R}^{2}=0.998$.

### 3.7.4 Data Tables from ${ }^{1} \mathrm{H}$ NMR Spectroscopy Kinetic Experiments

The kinetic data from ${ }^{1} \mathrm{H}$ NMR spectroscopy from which Figure 3.2 and Figure 3.3 were constructed is listed in the tables displayed in the following pages.

Table 3.10: Rate constant data for compound 3a in $\mathrm{D}_{2} \mathrm{O}$ buffers at $37^{\circ} \mathrm{C}, I=1 \mathrm{M}$.

| $\mathbf{p H}^{* *}$ | phosphate conc. / M | $\begin{aligned} & {\left[\mathrm{HPO}_{4}{ }^{2-}\right]} \\ & \text { conc. } / \mathrm{M} \end{aligned}$ | $k_{\text {obs }} \times 10^{6} / \mathrm{s}^{-1}$ | $k_{\text {deut }} \times 10^{6} / \mathrm{s}^{-1}$ | $k_{\text {hyd }} \times 10^{6} / \mathrm{s}^{-1}$ | $\boldsymbol{S}_{\text {f (deut) }}$ | $S_{\text {f }}$ (hyd) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## 4 Kinetic Studies on the Configurational Instability of $N$-Substituted Phenylglycine Amides

### 4.1 Introduction

The database mining studies reported in Chapter 2 showed the frequent occurrence of amide functional groups adjacent to stereogenic centres deemed at risk of configurational instability under physiological conditions, according to the assignments by Testa et al. ${ }^{1-3}$ (Table 1.1). In particular, the combination of a proton, an aromatic group, an amide bound through the carbonyl and an amide bound through nitrogen appeared 7 times in the 250 most frequently occurring combinations of substituents around a stereogenic centre for compounds in the ISAC database (Table 2.5). Stereogenic centres such as these, of the type R' ${ }^{\prime}$ 'RC-H with R groups that can stabilise a negative charge, are susceptible to base-catalysed proton abstraction mechanisms as discussed in Chapter 1. This chapter will therefore focus on molecules based on the 'chiral motif' exhibited in Scheme 4.1.

Scheme 4.1: Structures to be investigated in this chapter. $\mathrm{R}^{1}=-\mathrm{H},-\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{X}$, $\mathrm{R}^{2}=-\mathrm{CH}_{3},-\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{X}, \mathrm{X}=$ various substituents.

In comparison to the related ester compounds discussed in Chapter 3, it was expected that the compounds analysed in this chapter would display lower rate constants for $\mathrm{H} / \mathrm{D}$ exchange and racemisation. This expectation is based on the classification by Testa et al. (Table 1.1) of an amide substituent as 'acid-strengthening', rather than the 'strongly acid-strengthening' classification attributed to ester substituents. All else being equal, the molecules displayed in Scheme 4.1 should therefore have greater configurational stability than those investigated in Chapter 3.

Resonance delocalisation of the amide lone pair may be the reason for the reduced degree of 'acid-strengthening' displayed by amides in comparison to esters. Amides are known to display partial carbon-nitrogen double-bond character, ${ }^{4-8}$ as shown in Scheme 4.2.

Scheme 4.2: Amide resonance structures.
An adjacent carbonyl group can favour $H / D$ exchange and racemisation via an $S_{E} 1$ reaction by delocalisation of negative charge onto the carbonyl oxygen. However, for amide substituents the presence of resonance structure $\mathbf{B}$ diminishes delocalisation onto the carbonyl oxygen, as the carbonyl is already carrying an enhanced partial negative charge through delocalisation of the nitrogen lone pair.

Many drugs on the market contain stereogenic centres similar to those shown in Scheme 4.1 and those investigated in this chapter. These drugs include the antibiotic Cephalexin, ${ }^{9}$ antiepileptic Levetiracetam ${ }^{10}$ and proteasome inhibitors Bortezomib ${ }^{11}$ and Lenalidomide. ${ }^{12}$

### 4.2 Aims

There are 3 mains aims for this chapter.
First, to determine the rate constants of H/D exchange for the compounds illustrated in Scheme 4.1, under conditions mimicking physiological conditions. These kinetic studies will clarify whether stereogenic centres such as those in Scheme 4.1 are at risk of racemisation if administered as a drug.

Second, to understand the effect of changes in buffer concentration and temperature on the kinetics of H/D exchange. The former will inform us as to whether the process is general- or specific-base catalysed; the latter will allow determination of thermodynamic activation parameters for the $H / D$ exchange reaction.

Third, to investigate the effects each moiety on the stereogenic centre has on configurational stability. Quantification of the effect that alterations in molecular structure have on rate constants of $\mathrm{H} / \mathrm{D}$ exchange will provide information on the role of each substituent. Comparisons can also be made with the results presented in Chapter 3 for $N$-acetyl arylglycine esters. These comparisons may inform as to the mechanism by which H/D exchange occurs.

### 4.3 Synthesis of Compounds for Analysis

$N$-Substituted phenylglycine amides 6a-e, 7a-d and 8a-m (Scheme 4.4) were synthesised from commercially available starting materials. Phenylglycine amides 5a-e (Scheme 4.4) were also synthesised as intermediates.

j) $\mathrm{X}=m-\mathrm{Cl}, \mathrm{Y}=p-\mathrm{Me}$
e) $\mathrm{X}=\mathrm{H}, \mathrm{Y}=m-\mathrm{Cl}$
k) $\mathrm{X}=m-\mathrm{Cl}, \mathrm{Y}=\mathrm{H}$
f) $\mathrm{X}=p-\mathrm{Me}, \mathrm{Y}=m-\mathrm{Me}$
l) $\mathrm{X}=p-\mathrm{CF}_{3}, \mathrm{Y}=\mathrm{H}$

## 8a-I

Scheme 4.4: Phenylglycine amides 6a-g, 7a-d and 8a-l.
Phenylglycine amides 5a-e were synthesised (Scheme 4.5), from the corresponding phenylglycine methyl ester hydrochlorides 2a, c-e, $\mathbf{h}$ (see Chapter 3).

Scheme 4.5: Synthesis of phenylglycine amides 5a-e.
$N$-Substituted phenylglycine amides 6a-e and 7a-d were then synthesised from the appropriate phenylglycine amide 5a-e.

Scheme 4.6: Synthesis of $N$-substituted phenylglycine amides 6a-e, 7a-d.
The synthesis of $N$-acetyl phenylglycines $\mathbf{4 a}$, $\mathbf{c}, \mathbf{e}$, $\mathbf{h}$ was described in Chapter 3. From these, $N$-acetyl phenylglycine amides 8a-l were synthesised (Scheme 4.7).

Scheme 4.7: Synthesis of $N$-substituted phenylglycine amides 8a-l.
Details of procedures used in synthesis and characterisation of products can be found in the experimental (Section 4.6.2).

### 4.4 Results and Discussion

### 4.4.1 $N$-Acetyl Phenylglycine Primary Amides 6a-e

### 4.4.1.1 Initial H/D Exchange Kinetic Experiments at $37^{\circ} \mathrm{C}$

Preliminary H/D exchange studies focused on compound 6a. The compound was dissolved in $\mathrm{D}_{2} \mathrm{O}$ phosphate buffers, incubated at $37{ }^{\circ} \mathrm{C}$ and monitored over time using ${ }^{1} \mathrm{H}$ NMR spectroscopy, looking for a decrease in the normalised integration of the peak corresponding to the proton bound to the stereogenic centre (as in Chapter 3). For amide 6a at $37^{\circ} \mathrm{C}$ and $\mathrm{pH}^{* *} 7.4, \mathrm{H} / \mathrm{D}$ exchange does occur, but at a far lower rate than that observed for ester 3a under identical conditions. The normalised integration after 28 days incubation at a variety of buffer strengths is displayed in Table 4.1.

Table 4.1: Normalised integration of $\mathbf{6 a}$ after 28 days in $\mathrm{D}_{2} \mathrm{O}$ phosphate buffers of $\mathrm{pH}^{* *} 7.4$, $I=1 \mathrm{M}, 37^{\circ} \mathrm{C}$.

| Total buffer concentration / M |  | 0.1 |  | 0.2 |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 0.93 |  | 0.25 |  | 0.3 |  |
| Normalised Integration |  | 0.88 |  | 0.87 |  | 0.82 |

Because of the lengths of time that experiments would have to be monitored for in order to get accurate rate constants of deuteration for $\mathbf{6 a}$ at $37^{\circ} \mathrm{C}$, it was deemed unfeasible to follow H/D exchange in this manner for 6a. The only compound in the series 6a-e for which H/D exchange occurred rapidly enough to be monitored in this manner was $\mathbf{6 e}$, as the $p-\mathrm{CF}_{3}$ substituent is the most electron-withdrawing (has the highest Hammett $\sigma$ constant) of those synthesised. Rate constants of $\mathrm{H} / \mathrm{D}$ exchange at $37^{\circ} \mathrm{C}$ for $\mathbf{6 e}$ are displayed in Table 4.2.

Table 4.2: Rate constants of $\mathrm{H} / \mathrm{D}$ exchange of $\mathbf{6 e}$ in $\mathrm{D}_{2} \mathrm{O}$ phosphate buffers of $\mathrm{pH}^{* *} 7.4, I=1$ M, $37^{\circ} \mathrm{C}$, determined by ${ }^{1} \mathrm{H}$ NMR spectroscopy.

| phosphate conc. / M | [ $\left.\mathrm{HPO}_{4}{ }^{2}\right]$ conc. / M | $k_{\text {deut }} \times 10^{7} / \mathrm{s}^{-1}$ |
| :---: | :---: | :---: |
| 0.1 | 0.061 | $5.05 \pm 0.39$ |
| 0.2 | 0.122 | $8.73 \pm 0.37$ |
| 0.3 | 0.182 | $14.74 \pm 0.43$ |

These were plotted as a function of basic buffer component from which $k_{\mathrm{gb}}$ (as defined in Section 3.4.4) was determined (Figure 4.1).

Figure 4.1: $k_{\text {deut }}$ of 6 e at $37^{\circ} \mathrm{C}, \mathrm{pH}^{* *} 7.4, I=1 \mathrm{M}$, plotted as a function of basic buffer component. $k_{\mathrm{gb}}=(7.87 \pm 0.48) \times 10^{-6} \mathrm{~s}^{-1} \mathrm{M}$.

Figure 4.1 shows a slightly negative intercept with the $y$-axis, suggesting that there is negligible amount of specific-base catalysed or uncatalysed reaction under the conditions at which the experiments were performed. Contrasting the value of $k_{\mathrm{gb}}$ obtained for $\mathbf{6 e}$ with that of $\mathbf{3 h}$ (Chapter 3), provides a direct comparison of the effect on H/D exchange/racemisation of a methyl ester compared to a primary amide (Table 4.3).

Table 4.3: Comparison of $k_{\mathrm{gb}}$ at $37^{\circ} \mathrm{C}, \mathrm{pH}^{* *} 7.4, I=1 \mathrm{M}$ of compounds $\mathbf{3 h}$ and $\mathbf{6 e}$.

General-base catalysis as quantified by $k_{\mathrm{gb}}$ for methyl ester $\mathbf{3 h}$ is nearly 2 orders of magnitude more efficient than for primary amide $\mathbf{6 e}$. This difference is likely due to the propensity of the amide nitrogen to donate its lone pair, resulting in a negative charge on the carbonyl group (Section 4.1, Scheme 4.2). This also corroborates the assignment in Table 1.1 of ester groups as more strongly configurationally destabilising in comparison with amides. The observation that $k_{\mathrm{gb}}$ for methyl ester $\mathbf{3 h}$ is nearly 2 orders of magnitude greater than for primary amide $\mathbf{6 e}$ also fits with the $\mathrm{p} K_{\mathrm{a}}$ values of carbon acids determined by Richard et al. ${ }^{13}$ (Table 1.2). They
found that the $\mathrm{p} K_{\mathrm{a}}$ of the $\alpha$-carbon of methyl acetate was over two $\mathrm{p} K_{\mathrm{a}}$ units lower than that of acetamide.

Because of the longer periods of time required for $H / D$ exchange experiments of $\mathbf{6 a - d}$, it was not deemed possible to analyse them in the same way as compounds $\mathbf{3 a - 1}$ or $\mathbf{6 e}$. It was also impossible to analyse compounds 7a-d and 8a-l in this manner, as these compounds are too insoluble in $\mathrm{D}_{2} \mathrm{O}$ to allow sufficient concentrations for analysis through ${ }^{1} \mathrm{H}$ NMR spectroscopy. To avoid these problems, rate constants of H/D exchange were obtained using LCMS at higher temperatures. The higher temperatures increased the rate of the reactions and the greater sensitivity of the LCMS (compared with ${ }^{1}$ H NMR spectroscopy) allowed for lower concentrations of analyte to be used. As in Chapter 3, analysis was undertaken in $\mathrm{D}_{2} \mathrm{O}$ phosphate buffers. The solution was monitored over time using LCMS. Deuteriumincorporation was monitored by changes in the mass spectrogram over time (see Experimental Section 4.6.3.2).

### 4.4.1.2 LCMS Hammett Analysis at $90{ }^{\circ} \mathrm{C}$

Rate constants of $\mathrm{H} / \mathrm{D}$ exchange for $\mathbf{6 b}, \mathbf{6 d}$ and $\mathbf{6 e}$ were determined in $\mathrm{D}_{2} \mathrm{O}$ buffers of $\mathrm{pH}^{*}$ $7.4^{\dagger}$ at $90^{\circ} \mathrm{C}$ at a range of buffer concentrations using LCMS. Compounds $\mathbf{6 a}$ and $\mathbf{6 c}$ could not be analysed in the same way, as neither was sufficiently retained on the LCMS column.
 retention times long enough for analysis. Details of how rate constants were obtained using the LCMS instrument are outlined in the experimental (Section 4.6.3.2). Individual kinetic traces are displayed in the Appendix. Rate constants for H/D exchange as a function of basic buffer component for compounds $\mathbf{6 b}, \mathbf{6 d}$ and $\mathbf{6 e}$ are displayed in Figure 4.2.

[^14]

Figure 4.2: Rate constants of $\mathrm{H} / \mathrm{D}$ exchange as a function of basic buffer component for a) $\mathbf{6 b}$, b) $\mathbf{6 d}$, c) $\mathbf{6 e}$ in $\mathrm{D}_{2} \mathrm{O}$ phosphate buffers of $\mathrm{pH}^{*} 7.4, I=1$ M at $90^{\circ} \mathrm{C}$.

From Figure $4.2, k_{\mathrm{gb}}$ and $k_{0}{ }^{\prime}$ were obtained for compounds $\mathbf{6 b}, \mathbf{6 d}$ and $\mathbf{6 e}$ (Table 4.4).
Table 4.4: $k_{\mathrm{gb}}$ and $k_{0}$ ' for compounds $\mathbf{6 b}, \mathbf{6 d}$ and $\mathbf{6 e}$ in $\mathrm{D}_{2} \mathrm{O}$ phosphate buffers of $\mathrm{pH}^{*} 7.4, I=$ 1 M at $90^{\circ} \mathrm{C}$.

| Compound | $\boldsymbol{k}_{\mathrm{gb}} / \mathbf{s}^{-1} \mathbf{M}^{-1}$ | $k_{0}{ }^{\prime} / \mathbf{s}^{-1}$ |
| :---: | :---: | :---: |
| 6b | $(1.15 \pm 0.23) \times 10^{-4}$ | $(1.60 \pm 0.27) \times 10^{-5}$ |
| 6d | $(5.63 \pm 0.73) \times 10^{-4}$ | $(2.24 \pm 1.15) \times 10^{-5}$ |
| 6 e | $(2.73 \pm 0.16) \times 10^{-3}$ | $(1.91 \pm 0.19) \times 10^{-4}$ |

The results displayed in Table 4.4 show that $k_{0}{ }^{\prime}$ is much more significant in $\mathrm{H} / \mathrm{D}$ exchange of amides $\mathbf{6 b}, \mathbf{6 d}$ and $6 \mathbf{e}$ at $90^{\circ} \mathrm{C}$, than it was for methyl esters $\mathbf{3 a}$-h or amide $\mathbf{6 e}$ at $37^{\circ} \mathrm{C}$ and suggests a substantial degree of specific-base catalysis by $\mathrm{OH}^{-}$ions and/or uncatalysed reaction.

Hammett plots were constructed, correlating the values of $k_{\mathrm{gb}}$ displayed in Table 4.4, with both $\sigma$ and $\sigma^{-}$substituent constants (Figure 4.3).

Figure 4.3: Hammett plots of $k_{\mathrm{gb}}$ of $\mathbf{6 b}, \mathbf{6 d}$ and $\mathbf{6 e}$ at $90^{\circ} \mathrm{C}, \mathrm{pH}^{*}=7.4, I=1$ M , fitted to a) $\sigma$ constants, $\rho=2.02 \pm 0.12, \mathrm{R}^{2}=0.990$ and b) $\sigma^{-}$constants, $\rho$ $=1.61 \pm 0.10, \mathrm{R}^{2}=0.992$.

Figure 4.3 shows that the values determined for $k_{\mathrm{gb}}$ correlate reasonably well with both $\sigma$ and $\sigma^{-}$values. As in the case of the methyl esters (Section 3.4.6), distinguishing between the two sets of substituent constants is difficult as none of the substituents analysed have drastically different $\sigma$ and $\sigma^{-}$values, leaving little difference between graphs. This similarity between substituent constants results in similar $\rho$ values for both sets of substituent constants. These $\rho$ values are compared with those found for methyl ester compounds 3a-h in Table 4.5.

Table 4.5: $\rho$ values determined from $k_{\mathrm{gb}}$ of $\mathbf{6 b}, \mathbf{d}, \mathbf{e}$ at $90^{\circ} \mathrm{C}$ and $\mathbf{3 a - h}$ at $37^{\circ} \mathrm{C}, \mathrm{pH}^{*}=7.4, I=$ 1 M (from Figure 3.4).

| Series | $\sigma$ | $\sigma^{-}$ |
| :---: | :---: | :---: |
| 6b, d, e | $2.02 \pm 0.12$ | $1.61 \pm 0.10$ |
| 3a-h | $2.50 \pm 0.03$ | $2.07 \pm 0.02$ |

It should be noted that the $\rho$ values for the two series displayed in Table 4.5 were determined at different temperatures. As discussed in Section 1.8.2.1.2, reaction constants have been observed to be temperature dependent. Eqn 1.18 suggests $\rho$ values are dependent on $T^{1}$. This temperature dependence is a potential explanation for the greater magnitude of $\rho$ determined for the series $\mathbf{3 a} \mathbf{- h}$, and suggests that a greater $\rho$ value would be obtained for $\mathbf{6 b}, \mathbf{d}, \mathbf{e}$ if the experiments were to be carried out at $37^{\circ} \mathrm{C}$. However, as discussed in Section 1.8.2.1.2, a definitive relationship between $\rho$ and $T^{1}$ has not been conclusively proven. In any case, assuming that $\rho$ would be equal for $\mathbf{6 b}, \mathbf{d}, \mathbf{e}$ and $\mathbf{3 a} \mathbf{- h}$ at a specific temperature seems unwise. Ignoring the effect of temperature, it would generally be expected that the magnitude of $\rho$ for the primary amides would be higher than that seen for the methyl esters. As discussed in

Section 4.1 and illustrated in Scheme 4.2, electron-pair donation by the amide nitrogen results in a substantial negative charge build up on the carbonyl oxygen. This means that a negative charge built up on the stereogenic centre of $\mathbf{6 b}, \mathbf{d}, \mathbf{e}$ during H/D exchange cannot be stabilised through delocalisation onto the carbonyl oxygen as much as it can for 3a-h. As a result it would be expected that the stabilising effect of the aromatic group would be more important for $\mathrm{H} / \mathrm{D}$ exchange of $\mathbf{6 b}, \mathbf{d}$, e than for $\mathbf{3 a - l}$, and larger $\rho$ values would be seen. An increased dependence on the aromatic group for stabilisation is the proposed cause for the large magnitude of $\rho=3.58$ seen for profen thioesters, as discussed in Section 3.4.6 (Scheme 3.9). ${ }^{16}$ The $\rho$ value of 1.61 , from $k_{\mathrm{gb}}$ values of $\mathbf{6 b}, \mathbf{d}, \mathbf{e}$ (using $\sigma^{-}$constants) at $90^{\circ} \mathrm{C}$, sits between the $\rho$ values of 2.07 and 1.15 determined from $k_{\mathrm{gb}}$ values of $\mathbf{3 a}$-h (using $\sigma^{-}$constants) at $37^{\circ} \mathrm{C}$ and for the racemisation of phenylglycines at $80^{\circ} \mathrm{C}$ (Smith and Sivakua ${ }^{17}$ ) respectively. In both of the latter cases, an $\mathrm{S}_{\mathrm{E}} 1$ mechanism was concluded based on equivalent rate constants of racemisation and H/D exchange (see Section 1.3). These $\rho$ values and the similarities in molecular structure between the three sets of compounds suggest that an $\mathrm{S}_{\mathrm{E}} 1$ mechanism is also likely for $\mathrm{H} / \mathrm{D}$ exchange of $\mathbf{6 b}$, $\mathbf{d}$, e. Computational studies providing further evidence towards this conclusion will be presented in Chapter 5.

### 4.4.1.3 Determination of Thermodynamic Activation Parameters for H/D Exchange Reactions of $6 e$

In order to determine the activation energy and pre-exponential factor according to the Arrhenius equation (Section 1.9.1), and enthalpy and entropy of activation according to the Eyring equation (Section 1.9.2) for the general-base catalysed H/D exchange of $\mathbf{6 e}, k_{\mathrm{gb}}$ was determined at 60,70 and $80^{\circ} \mathrm{C}$ using the LCMS method. These rate constants were combined with the values of $k_{\mathrm{gb}}$ determined at $90^{\circ} \mathrm{C}$ using the LCMS method and the rate constant at 37 ${ }^{\circ} \mathrm{C}$ using the ${ }^{1} \mathrm{H}$ NMR spectroscopic method to produce Arrhenius and Eyring plots, which were used to obtain the activation parameters. Rate constants of $\mathrm{H} / \mathrm{D}$ exchange as a function of basic buffer component for compound $\mathbf{6 e}$ at 60,70 and $80^{\circ} \mathrm{C}$ are displayed in Figure 4.4.

Figure 4.4: Rate constants of H/D exchange as a function of basic buffer component for $6 \mathbf{e}$ in $\mathrm{D}_{2} \mathrm{O}$ phosphate buffers of $\mathrm{pH}^{*} 7.4, I=1 \mathrm{M}$ at a) $60^{\circ} \mathrm{C}$, b) $70^{\circ} \mathrm{C}$ and c) $80^{\circ} \mathrm{C}$.

The values of $k_{\mathrm{gb}}$ and $k_{0}{ }^{\prime}$ determined for $\mathbf{6 e}$ from Figure 4.4 along with those determined at 37 and $90^{\circ} \mathrm{C}$ are displayed in Table 4.6.

Table 4.6: values of $k_{\mathrm{gb}}$ and $k_{0}{ }^{\prime}$ for $6 \mathbf{e}$ in $\mathrm{D}_{2} \mathrm{O}$ phosphate buffers of $\mathrm{pH} * * 7.4, I=1 \mathrm{M}$.

| Temperature $/{ }^{\circ} \mathbf{C}$ | $\boldsymbol{k}_{\mathbf{g b}} / \mathbf{s}^{-1} \mathbf{M}^{-1}$ |  | $\boldsymbol{k}_{\mathbf{0}}{ }^{\prime} / \mathbf{s}^{-\mathbf{1}}$ |
| :---: | :---: | :---: | :---: |
|  | $(7.87 \pm 0.48) \times 10^{-6}$ |  | $(-1.23 \pm 6.10) \times 10^{-8}$ |
| $\mathbf{6 0}$ |  | $(2.19 \pm 0.39) \times 10^{-4}$ |  |
| $\mathbf{7 0}$ | $(6.05 \pm 0.64) \times 10^{-4}$ |  | $(1.72 \pm 1.04) \times 10^{-5}$ |
| $\mathbf{8 0}$ | $(1.04 \pm 0.07) \times 10^{-3}$ |  | $(8.61 \pm 0.88) \times 10^{-5}$ |
| $\mathbf{9 0}$ | $(2.73 \pm 0.16) \times 10^{-3}$ |  | $(1.91 \pm 0.19) \times 10^{-4}$ |

An Arrhenius plot of the data in Table 4.6 is shown in Figure 4.5.

Figure 4.5: Arrhenius plot for general-base catalysed H/D exchange of $\mathbf{6 e}$, in $\mathrm{D}_{2} \mathrm{O}$ phosphate buffers at $\mathrm{pH}^{*} 7.4, I=1 \mathrm{M} . y$-axis intercept $=\ln A=$ $28.38 \pm 1.44$. Gradient $=-E_{\mathrm{a}} / R=-12428.02 \pm 490.636 \mathrm{~K}$.

From the intercept and gradient of Figure 4.5, an activation energy $\left(E_{\mathrm{a}}\right)$ of $103.33 \pm 4.08 \mathrm{~kJ}$ $\mathrm{mol}^{-1}$ and a pre-exponential factor $(A)$ of $2.12 \times 10^{12} \mathrm{~s}^{-1} \mathrm{M}^{-1}\left(\min 5.01 \times 10^{11} \mathrm{~s}^{-1} \mathrm{M}^{-1}\right.$, max 8.98 $\times 10^{12} \mathrm{~s}^{-1} \mathrm{M}^{-1}$ ) were determined for general-base catalysed $\mathrm{H} / \mathrm{D}$ exchange of 6 e .

An Eyring plot of the data in Table 4.6 is displayed in Figure 4.6.

Figure 4.6: Eyring plot of general-base catalysed H/D exchange of $\mathbf{6 e}$, in $\mathrm{D}_{2} \mathrm{O}$ phosphate buffers at $\mathrm{pH}^{*} 7.4, I=1 \mathrm{M} . y$-axis intercept $=\ln \left(k_{\mathrm{B}} / h\right)+$ $\Delta S^{\ddagger} / R=21.57 \pm 1.45$. Gradient $=-\Delta H^{\ddagger} / R=-12094.01 \pm 492.97 \mathrm{~K}$.

From the intercept and gradient of Figure 4.6, an enthalpy of activation $\left(\Delta H^{\ddagger}\right)$ of $100.55 \pm$ $4.10 \mathrm{~kJ} \mathrm{~mol}^{-1}$ and entropy of activation $\left(\Delta S^{\ddagger}\right)$ of $-18.21 \pm 12.06 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1}$ for general-base catalysed $H / D$ exchange of $6 e$ were determined.

It is notable that the percentage error margins on the value determined for $A$ from Figure 4.5 and $\Delta S^{\ddagger}$ from Figure 4.6 are both very large. This is because each value was obtained from the intercept with the $y$-axis, which involves a relatively long extrapolation from a small cluster of points. This long extrapolation magnifies any error in the calculation. As an alternative, both $A$ and $\Delta S^{\ddagger}$ were calculated at each individual data point using the values of $E_{\mathrm{a}}$ and $\Delta H^{\ddagger}$ calculated from Figure 4.5 and Figure 4.6 respectively by substituting into eqn (1.23) and (1.26). These values are summarised in Table 4.7.

Table 4.7: $A$ and $\Delta S^{\ddagger}$ calculated at individual data points, using the values of $E_{\mathrm{a}}$ and $\Delta H^{\ddagger}$ determined from Figure 4.5 and Figure 4.6.

| T/ ${ }^{\circ} \mathrm{C}$ | $k_{\mathrm{gb}} / \mathbf{s}^{-1} \mathbf{M}^{-1}$ | $\boldsymbol{A} / \mathbf{s}^{-1} \mathbf{M}^{-1}$ | $\Delta S^{\ddagger} / \mathbf{J ~ K}^{-1} \mathbf{~ m o l}^{-1}$ |
| :---: | :---: | :---: | :---: |
| 37 | $(7.87 \pm 0.48) \times 10^{-6}$ | $1.97 \times 10^{12}$ | -18.86 |
| 60 | $(2.19 \pm 0.39) \times 10^{-4}$ | $3.44 \times 10^{12}$ | -14.17 |
| 70 | $(6.05 \pm 0.64) \times 10^{-4}$ | $3.21 \times 10^{12}$ | -14.76 |
| 80 | $(1.04 \pm 0.07) \times 10^{-3}$ | $1.98 \times 10^{12}$ | -18.79 |
| 90 | $(2.73 \pm 0.16) \times 10^{-3}$ | $1.97 \times 10^{12}$ | -18.83 |

Table 4.7 shows that calculated $A$ and $\Delta S^{\ddagger}$ values are very similar for experiments at 37,80 and $90^{\circ} \mathrm{C}$. These are the data points with the smallest error margins from the original experiments and hence should be the most accurate values for $A$ and $\Delta S^{\ddagger}$. Using these values gives $\Delta S^{\ddagger}=-17.08 \pm 2.40 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1}$ (errors calculated from standard deviation).

It is of interest to compare the activation parameters for general-base catalysed $\mathrm{H} / \mathrm{D}$ exchange of $\mathbf{6 e}$ to other examples. Some values of $\Delta H^{\ddagger}$ and $\Delta S^{\ddagger}$ for racemisation reactions thought to proceed through similar mechanism are listed in Table 4.8, 4.9 and 4.10.

Table 4.8: Activation parameters for racemisation of amino acids by Smith et al. ${ }^{17,18}$

| Amino Acid | $\Delta H^{\ddagger} / \mathrm{kJ} \mathrm{mol}^{-1}$ | $\Delta S^{\ddagger} / \mathbf{J ~ K}^{-1} \mathrm{~mol}^{-1}$ |
| :---: | :---: | :---: |
| alanine | $115.5 \pm 2.5$ | $-78.2 \pm 5.4$ |
| valine | $116.6 \pm 1.3$ | $-85.4 \pm 2.9$ |
| isoleucine | $113.4 \pm 2.5$ | $-90.4 \pm 5.9$ |
| leucine | $114.2 \pm 2.1$ | $-84.5 \pm 4.6$ |
| phenylalanine | $97.1 \pm 0.8$ | $-117.2 \pm 2.1$ |
| phenylglycine | $83.3 \pm 0.0$ | $-121.3 \pm 0.4$ |
| $m$-nitrophenylglycine | $84.1 \pm 0.4$ | $-102.5 \pm 1.7$ |
| $m$-chlorophenylglycine | $83.3 \pm 1.3$ | $-110.9 \pm 3.8$ |
| p-chlorophenylglycine | $82.0 \pm 1.3$ | $-118.8 \pm 3.3$ |
| $p$-methylphenylglycine | $85.4 \pm 0.4$ | $-118.4 \pm 1.3$ |
| $p$-methoxyphenylglycine | $84.9 \pm 0.4$ | $-120.9 \pm 1.3$ |

Table 4.9: Activation parameters for racemisation of 5 -monosubstituted hydantoins from Reist et al. ${ }^{19}$

| Hydantoin C(5) Substituent | $\Delta H^{\ddagger} / \mathrm{kJ} \mathrm{mol}{ }^{-1}$ | $\Delta S^{\ddagger} / \mathbf{J ~ K}^{-1} \mathrm{~mol}^{-1}$ |
| :---: | :---: | :---: |
| -Ph | $72.3 \pm 4.0$ | $-68.2 \pm 5.0$ |
| $-\mathrm{CH}_{2} \mathrm{OH}$ | $76.7 \pm 2.8$ | $-86.6 \pm 4.6$ |
| $-\mathrm{NHONH}_{2}$ | $94.1 \pm 2.1$ | $-39.3 \pm 1.3$ |
| $-\mathrm{CH}_{2} \mathrm{Ph}$ | $94.3 \pm 2.5$ | $-43.1 \pm 1.7$ |
| $-\mathrm{CH}_{3}$ | $85.3 \pm 2.1$ | $-77.0 \pm 2.9$ |
| $-\mathrm{CH}_{2} \mathrm{COOH}$ | $98.4 \pm 3.2$ | $-42.3 \pm 2.1$ |
| $-\mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}$ | $80.7 \pm 3.0$ | $-105.4 \pm 6.7$ |

Table 4.10: Activation parameters for general-base catalysed racemisation of $N$-substituted 5benzylhydantoins by phosphate buffer at $\mathrm{pH} 7.2 .{ }^{20}$

| Hydantoin $N$ - Substituent | $\Delta H^{\ddagger} / \mathrm{kJ} \mathrm{mol}{ }^{-1}$ | $\Delta S^{\ddagger} / \mathrm{J} \mathrm{K}^{-1} \mathrm{~mol}^{-1}$ |
| :---: | :---: | :---: |
| $-\mathrm{CH}_{3}$ | $83.7 \pm 0.8$ | $-55.2 \pm 2.9$ |
| $-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OCH}_{3}$ | $87.9 \pm 2.9$ | $-44.8 \pm 10.0$ |
| $-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{~N}^{+}\left(\mathrm{CH}_{3}\right)_{3}$ | $93.7 \pm 2.1$ | $-13.4 \pm 6.7$ |

It should be noted that the values in Table 4.8 and 4.9 appear to have been calculated from $k_{\text {obs }}$ at a single buffer concentration, rather than from the second-order rate constants obtained from the gradient of $k_{\text {obs }}$ plotted against buffer concentration. This means that the results have not been normalised to a standard state concentration of $1 \mathrm{~mol} \mathrm{~L}^{-1}$, and this will result in an incorrect entropy of activation. If an extent of specific-base catalysis contributes to the overall rate constant as well, the problem is made worse as the enthalpy of activation is a combination of two separate reactions (specific- and general-base catalysed).

The values determined for $\Delta H^{\dagger}$ for $\mathrm{H} / \mathrm{D}$ exchange of $\mathbf{6 e}$ are of similar magnitude to those displayed in Table 4.8, 4.9 and 4.10. This value is indicative of bond breaking being important in the rate-determining step, which is consistent with an $\mathrm{S}_{\mathrm{E}} 1$ mechanism.

The negative value of $\Delta S^{\ddagger}$ seen for $\mathbf{6 e}$ is to be expected, as bringing molecules together for reaction reduces the degrees freedom. Increased solvation (and hence negative $\Delta S^{\ddagger}$ ) from the formation of a negative charge is counterbalanced by the dispersal of the doubly negative charge from the phosphate ion. However, the value determined for $\Delta S^{\ddagger}$ of $\mathrm{H} / \mathrm{D}$ exchange of $\mathbf{6 e}$ seems remarkably small in comparison with those in Table 4.10.

The entropies of activation in Table 4.10 for $N$-substituted 5-benzylhydantoins have been corrected in the same manner as for $\mathbf{6 e}$. Of the three entries displayed in Table 4.10, the quaternary amine substituted hydantoin has a less negative value of $\Delta S^{\ddagger}$ than the other entries. This is thought to be partially because of intramolecular stabilisation of a negative charge built up during H/D exchange by the positively charged amine, but mainly due to solvation differences. As there is already a positive charge on the hydantoin the solvation shell is already tightly ordered, meaning less reorganisation necessary upon deprotonation at the stereogenic centre and hence a smaller $\Delta S^{\ddagger}$. The value of $-13.4 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1}$ observed for the quaternary amine substituted hydantoin is the most similar to that observed for $\mathbf{6 e}$. As no such positive charge exists in 6 e it would be expected to exhibit a $\Delta S^{\ddagger}$ closer to those displayed by the $N$-methyl and $N$-ethyl methoxy substituted hydantoins in Table 4.10. The differences between these values and that determined for $\mathbf{6 e}$ may be due to the extent to which proton transfer is complete in the activated complex. One manner in which this could be resolved is through determination and comparison of the Brønsted $\beta$-coefficients.

### 4.4.1.4 High Temperature Kinetic Experiments as a Predictive Tool for Physiological Temperatures

Alongside its use in the determination of thermodynamic activation parameters, the data in Table 4.6 can be used to assess the potential for using experiments at high temperatures as a guide for potential configurational instability under physiological conditions. If accurate predictions of unknown rate constants of $\mathrm{H} / \mathrm{D}$ exchange at physiological temperatures could be made based on high temperature experiments, experimentation on a potential drug molecule could be carried out at higher temperatures, giving results more quickly and the process of analysis more amenable.

An Eyring plot for $\mathrm{H} / \mathrm{D}$ exchange of $\mathbf{6 e}$, with the data point at $37^{\circ} \mathrm{C}$ omitted, was constructed. The extrapolated line of best fit was used to make a 'prediction' for the value of $k_{\mathrm{gb}}$ at $37^{\circ} \mathrm{C}$, giving a 'predicted' $k_{\mathrm{gb}}$ at $37^{\circ} \mathrm{C}$ of $2.39 \times 10^{-5} \mathrm{~s}^{-1} \mathrm{M}^{-1}$. The experimental $k_{\mathrm{gb}}$ at $37^{\circ} \mathrm{C}$ is $(7.87 \pm$ $0.48) \times 10^{-6} \mathrm{~s}^{-1} \mathrm{M}^{-1}$.

The 'predicted' value of $k_{\mathrm{gb}}$ is approximately 3 times higher than the experimentally determined value. Although this is not particularly accurate, it is within an order of magnitude. This type of approximation could therefore be of use in drug development to determine whether a molecule may be of a high risk of being configurationally unstable under physiological conditions. ${ }^{\ddagger}$

### 4.4.2 N-Acetyl Phenylglycine Anilides 8a-I

Compounds 8a-I (Scheme 4.8) were also studied using LCMS to obtain rate constants of H/D exchange.

[^15]

l) $\mathrm{X}=p-\mathrm{CF}_{3}, \mathrm{Y}=\mathrm{H}$

8a-1
Scheme 4.8: Phenylglycine amides 8a-l.
Because of the number of compounds to analyse, it was not possible to analyse these compounds at a range of different buffer concentrations, as was done for $\mathbf{6 b}, \mathbf{d}, \mathbf{e}$. Therefore, each compound 8a-l was only analysed at a single buffer concentration and temperature. Data for all experiments are collected in the appendix. The results for each compound are summarised in Table 4.11.

Table 4.11: Rate constants for $\mathrm{H} / \mathrm{D}$ exchange of $\mathbf{8 a - 1}$ in $\mathrm{D}_{2} \mathrm{O} 0.3 \mathrm{M}$ phosphate buffers, $\mathrm{pH}^{*}$ $7.4, I=1 \mathrm{M}$ at $90^{\circ} \mathrm{C}$, determined by LCMS analysis.

| Compound | X-substituent | Y-substituent | $k_{\text {deut }} / \mathrm{s}^{-1 \mathrm{a}}$ |
| :---: | :---: | :---: | :---: |
| 8 a | - | - | $(5.45 \pm 0.25) \times 10^{-5}$ |
| 8b | - | $p$-Me | $(3.32 \pm 0.35) \times 10^{-5}$ |
| 8 c | - | $m$-Me | $(4.24 \pm 0.69) \times 10^{-5}$ |
| 8d | - | $p-\mathrm{Cl}$ | $(6.41 \pm 0.43) \times 10^{-5}$ |
| 8 e | - | $m-\mathrm{Cl}$ | $(8.86 \pm 0.25) \times 10^{-5}$ |
| 8 f | $p$-Me | $m$-Me | $(2.22 \pm 0.46) \times 10^{-5}$ |
| 8 g | $p$-Me | - | $(2.61 \pm 0.44) \times 10^{-5}$ |
| 8h | $p$-Me | $m-\mathrm{Cl}$ | $(4.54 \pm 0.25) \times 10^{-5}$ |
| $8 i$ | $p-\mathrm{Cl}$ | - | $(1.18 \pm 0.05) \times 10^{-4}$ |
| 8j | $m-\mathrm{Cl}$ | $p$-Me | $(1.44 \pm 0.04) \times 10^{-4}$ |
| 8k | $m-\mathrm{Cl}$ | - | $(2.12 \pm 0.04) \times 10^{-4}$ |
| 81 | $p-\mathrm{CF}_{3}$ | - | $(6.00 \pm 0.52) \times 10^{-4}$ |

[^16]Because experiments were only carried out at one buffer concentration, it is not possible to separate out rate constants for general- and specific- base catalysis. As a result, comparisons
between the values should be made with care. Nevertheless, a Hammett analysis of the data in Table 4.11 is still of interest.

### 4.4.2.1 Hammett Analysis of Phenylglycine Aromatic Substituents

Hammett plots of the data displayed in Table 4.11 for compounds $\mathbf{8 a}, \mathbf{8 g}, \mathbf{8 i}, \mathbf{8 k}$ and $\mathbf{8 1}$ (varying substituents on phenylglycine ring, no substituents on aniline ring) were constructed, using both $\sigma$ and $\sigma^{-}$substituent constants (Figure 4.7).

Figure 4.7: Hammett plots of $k_{\text {deut }}$ for compounds $\mathbf{8 a}, \mathbf{8 g}, \mathbf{8 i}, \mathbf{8 k}$ and $\mathbf{8 1}$ determined at 0.3 M phosphate concentration, $\mathrm{pH}^{*} 7.4, I=1 \mathrm{M}, 90^{\circ} \mathrm{C}$, correlated with a) $\sigma$ substituent constants, $\rho=1.69 \pm 0.14, \mathrm{R}^{2}=0.975$ and b) $\sigma^{-}$substituent constants, $\rho=1.58 \pm 0.05, \mathrm{R}^{2}=0.997$.

Figure 4.7 shows that the data in Table 4.1 correlates reasonably well with both $\sigma$ and $\sigma^{-}$ substituent constants. Again, the small differences between $\sigma$ and $\sigma^{-}$for the substituents available make distinguishing between the two sets of substituent constants difficult. Nevertheless, both the size of the error margin of $\rho$ and the $\mathrm{R}^{2}$ values suggest a slightly better correlation with the $\sigma^{-}$substituent constants. A better correlation with $\sigma^{-}$is consistent with negative charge being built up on the carbon at the stereogenic centre, where it can be directly resonance-delocalised onto the Hammett substituent.

The value of $\rho$ of 1.58 found for $k_{\text {deut }}$ of $\mathbf{8 a}, \mathbf{g}, \mathbf{i}, \mathbf{k}, \mathbf{l}$ is very similar to that of 1.61 found from $k_{\mathrm{gb}}$ of $\mathbf{6 b}$, $\mathbf{d}$, e suggesting a similar mechanism of $\mathrm{H} / \mathrm{D}$ exchange between the two sets of compounds. Hence, the $S_{E} 1$ mechanism is the probable mechanism of $H / D$ exchange of $8 \mathbf{a}, \mathbf{g}$, $\mathrm{i}, \mathrm{k}, \mathrm{l}$.

### 4.4.2.2 Hammett Analysis of Aniline Aromatic Substituents

A Hammett plot was also constructed for the $\mathrm{H} / \mathrm{D}$ exchange reaction of compounds 8a-e. In all five of these compounds the phenylglycine ring remains unsubstituted, whilst the substituent on the aniline ring is varied. This provides an indication as to the amount of stabilisation of negative charge provided by the aniline aromatic group. As no direct resonance delocalisation of a negative charge built up on the stereogenic centre onto substituents on the aniline ring is possible, the data was only correlated with Hammett $\sigma$ constants (Figure 4.8).

Figure 4.8: Hammett plot of $k_{\text {deut }}$ for compounds 8a-e, at 0.3 M phosphate concentration, $\mathrm{pH}^{*} 7.4, I=1 \mathrm{M}, 90^{\circ} \mathrm{C} . \rho=0.65 \pm 0.09, \mathrm{R}^{2}=0.933$.

Figure 4.8 shows that the Hammett $\rho$ value for H/D exchange of 8a-e is significantly lower than that seen for the series $\mathbf{8 a}, \mathbf{g}, \mathbf{i}, \mathbf{k}, \mathbf{l}$. The difference in $\rho$ values is attributed to the number of bonds between the site of $H / D$ exchange and the aromatic group upon which the substituents are being varied. The position of the aromatic ring with substituents in the series $\mathbf{8 a}-\mathbf{e}$ is three bonds away from the reaction site, as opposed to only one bond in the series $\mathbf{8 a}$, $\mathbf{g}, \mathbf{i}, \mathbf{k}, \mathbf{l}$, meaning the transmission of any electronic effect is attenuated. This results in the lower observed $\rho$ value ( $c f$. Section 1.8.2.1.1, Table 1.7).

The $\rho$ value of 0.65 obtained for $\mathrm{H} / \mathrm{D}$ exchange of the series is of a similar magnitude to other examples where the reaction site is more than one bond away from the substituted aromatic ring, and is not in direct conjugation. Some examples are shown in Table 4.12.

Table 4.12: Examples of reactions with $\rho$ values similar to that derived from Figure 4.8. ${ }^{21}$

| Reaction $^{\text {a }}$ |  | Conditions |  |
| :---: | :---: | :---: | :---: |
|  |  | $88 \% \mathrm{EtOH}, 30^{\circ} \mathrm{C}$ | 0.82 |
| $\mathrm{ArCH}_{2} \mathrm{COOC}_{2} \mathrm{H}_{5}+\mathrm{OH}^{-} \rightarrow \mathrm{ArCH}_{2} \mathrm{COO}^{-}$ |  | 0.49 |  |
| $\mathrm{ArCH}_{2} \mathrm{CH}_{2} \mathrm{COOC}_{2} \mathrm{H}_{5}+\mathrm{OH}^{-} \rightarrow \mathrm{ArCH}_{2} \mathrm{CH}_{2} \mathrm{COO}^{-}$ |  | $88 \% \mathrm{EtOH}, 30^{\circ} \mathrm{C}$ |  |
| $\mathrm{ArCH}_{2} \mathrm{Cl}+\mathrm{I}^{-} \rightarrow \mathrm{ArCH}_{2} \mathrm{I}$ |  | Acetone, $20^{\circ} \mathrm{C}$ | 0.79 |
| $\mathrm{ArCH}_{2} \mathrm{~F}+\mathrm{OH}^{-} \rightarrow \mathrm{ArCH}_{2} \mathrm{OH}$ |  | $95 \% \mathrm{EtOH}, 76^{\circ} \mathrm{C}$ | 0.45 |

${ }^{2} \mathrm{Ar}=\mathrm{X}-\mathrm{C}_{6} \mathrm{H}_{4}-$ where X is the variable substituent

The values of $\rho<1$ in the examples shown in Table 4.12 and in the H/D exchange of 8a-e, suggests that the amount of negative charge delocalised onto the aromatic ring in these examples is less than that found in the dissociation of benzoic acids.

Transmission of electron-withdrawing effects through a secondary amide bond in the manner shown for 8a-e has been observed through ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ and ${ }^{15} \mathrm{~N}$ NMR spectroscopy. ${ }^{22-24}$ Electronwithdrawing substituents on the anilide ring in benzanilides cause an upfield chemical shift of the proton and carbon signals of the acyl aromatic group in good agreement with Hammett $\sigma$ values.

The effect of varying substitution patterns on the aromatic ring of anilide compounds was investigated by Bergon and Calmon ${ }^{25}$ on the rate constants of hydrolysis of methyl carbanilates at $25^{\circ} \mathrm{C}$ (Scheme 4.9).

Scheme 4.9: Alkaline hydrolysis of methyl carbanilates.
A $\rho$ value of 1.06 was determined for electron-withdrawing X-substituents in the reaction depicted in Scheme 4.9. This contrasts with the value of 0.65 determined for H/D exchange of 8a-e, which also shows transmission of the electronic effect through the nitrogen atom of an anilide group. The greater value determined for the reaction in Scheme 4.9 is likely because the site of reaction is the carbonyl carbon, whereas for $H / D$ exchange of 8a-e the reaction site is the $\alpha$-carbon.

### 4.4.2.3 Dual Parameter Analysis

A 3D Hammett plot of the data in Table 4.11 was constructed (Figure 4.9), with X-substituents correlated with $\sigma^{-}$constants and Y -substituents correlated with $\sigma$ constants.

Figure 4.9: Hammett plot of $k_{\text {deut }}$ for compounds $\mathbf{8 a - I}$ determined at 0.3 M phosphate concentration, $\mathrm{pH}^{*} 7.4, I=1 \mathrm{M}, 90^{\circ} \mathrm{C}$. X-substituents correlate with $\sigma^{-}$constants; Y-substituents correlate with $\sigma$ constants. $\rho=(1.69 \pm$ $0.05) x+(0.71 \pm 0.06) y$.

Figure 4.9 shows a good correlation with the Hammett substituent constants in both the X and Y-positions for 8a-I. The magnitude of the slopes in both the X - and Y -directions of Figure 4.9, are similar to the $\rho$ values determined in Figure 4.7 and Figure 4.8. The good fit to the data using a two-parameter fit suggests there is no need for a cross-interaction term (Section 1.8.2.3). We note, however, that the absence of a requirement for a cross-interaction term may be because there is not a great range in the values of the substituent constants in either the X - or Y - direction.

### 4.4.3 $N$-Benzoyl Phenylglycine Amides 7a-d

The LCMS method was also used to obtain rate constants for $\mathrm{H} / \mathrm{D}$ exchange of 7a-d. As with 8a-l, each compound was only analysed at a single buffer concentration and temperature. Individual plots are displayed in the appendix. The results for each compound are displayed in Table 4.13.

Table 4.13: Rate constants of $\mathrm{H} / \mathrm{D}$ exchange of $7 \mathbf{a}-\mathrm{d}$ in $\mathrm{D}_{2} \mathrm{O}$ phosphate buffers of concentration $0.3 \mathrm{M}, \mathrm{pH}^{*} 7.4, I=1 \mathrm{M}$ at $90^{\circ} \mathrm{C}$, determined by LCMS analysis.

| Compound |  | Y-substituent $^{\mathbf{a}}$ |  |
| :---: | :---: | :---: | :---: |
|  | - | $\boldsymbol{k}_{\text {deut }} / \mathbf{s}^{\mathbf{- 1 b}}$ |  |
| $\mathbf{7 a}$ | $p-\mathrm{OM}$ |  | $(6.50 \pm 0.45) \times 10^{-5}$ |
| $\mathbf{7 b}$ | $p-\mathrm{OCF}_{3}$ |  | $(5.06 \pm 0.25) \times 10^{-5}$ |
| $\mathbf{7 c}$ | $p-\mathrm{CF}_{3}$ | $(8.05 \pm 0.58) \times 10^{-5}$ |  |
| $\mathbf{7 d}$ |  | $(9.89 \pm 0.47) \times 10^{-5}$ |  |

[^17]A Hammett plot of the data in Table 4.13 is displayed in Figure 4.10.

Figure 4.10: Hammett plot of $k_{\text {deut }}$ for $\mathbf{7 a - d}$ determined at 0.3 M phosphate concentration, $\mathrm{pH}^{*} 7.4, I=1 \mathrm{M}, 90^{\circ} \mathrm{C} . \rho=0.35 \pm 0.02, \mathrm{R}^{2}=0.992$.

The Hammett analysis of 7a-d in Figure 4.10 shows a $\rho$ value of 0.35 . As with compounds 8a-e, this value reflects the number of bonds between the negative charge and the aromatic substituent. The $\rho$ value of 0.35 for $\mathbf{7 a - d}$, is less than the $\rho$ value of 0.65 for $\mathbf{8 a - e}$ (Figure 4.8). This suggests that a negative charge is less well transmitted through a secondary amide bond if it is orientated with the nitrogen bound to the site of negative charge build up.

### 4.4.4 Steric and Electronic Effects

Comparison of the rate of H/D exchange between molecular scaffolds 6 and $\mathbf{8}$ shows an interesting result. In Section 3.4.7, the rate constants of H/D exchange for $\mathbf{3 a}, \mathbf{3 i}$ and $\mathbf{3 j}$ were compared. It was found that increasing the size of the ester group markedly reduced the rate constants of H/D exchange (and hydrolysis). This was attributed to increasing steric hindrance preventing the general base from attacking the stereogenic centre. A similar effect was expected for the comparison of $k_{\text {deut }}$ between amides $\mathbf{6 e}$ and $\mathbf{8 1}$, which are the same except for the nature of the amide group (primary in $\mathbf{6 e}$, substituted with a phenyl group in 81). However, comparison between $6 \mathbf{e}$ and $\mathbf{8 1}$ shows similar rate constants under identical conditions (Table 4.14).

Table 4.14: Comparison of $k_{\text {deut }}$ for $\mathbf{6 e}$ and 81 at $90^{\circ} \mathrm{C}$, in $0.3 \mathrm{M} \mathrm{D}_{2} \mathrm{O}$ phosphate buffers of $\mathrm{pH}^{*} 7.4, I=1 \mathrm{M}$.

| $\mathbf{R}$ group | $\boldsymbol{k}_{\text {deut }} \times 1 \mathbf{1 0}^{4} / \mathbf{s}^{-1}$ |
| :---: | :---: |
| $-\mathrm{H}(\mathbf{6 e})$ | $6.62 \pm 0.21$ |
| $-\mathrm{C}_{6} \mathrm{H}_{5}(\mathbf{8 1})$ | $6.00 \pm 0.52$ |

The values of $k_{\text {deut }}$ in Table 4.14 are the same within error margins. This is somewhat surprising in light of the result mentioned earlier for the different ester compounds, as a bulky phenyl group on the amide would provide far more steric hindrance than the esters investigated. If this steric hindrance is present, it would suggest that the phenyl amide substituent present in $\mathbf{8 1}$ is significantly more configurationally destabilising than the primary amide in $\mathbf{6 e}$, cancelling its rate-retarding steric effect. If this is the case, this may be due to the difference in resonance delocalisation between the two groups.

Delocalisation of the amide nitrogen lone pair onto the carbonyl oxygen will restrict any negative charge developing on the stereogenic centre during H/D exchange being delocalised onto the carbonyl oxygen (Scheme 4.2). This is a potential reason for the lower rates of racemisation seen when an ester group is replaced by an amide, and thus for the different classifications of amide and ester groups by Testa et al. (Table 1.1). However, for a phenyl-substituted amide the nitrogen lone-pair can be delocalised onto the phenyl ring (Scheme 4.10).

Scheme 4.10: Delocalisation of a phenyl amide nitrogen lone-pair onto aromatic ring.

The delocalisation shown in Scheme 4.10 will mean less negative charge build up on the carbonyl oxygen, allowing for greater stabilisation of any negative charge built up on the stereogenic centre during $H / D$ exchange. It appears to be the case that the decrease in configurational stability from these electronic factors offsets the increase in configurational stability from steric hindrance. This results in similar rate constants of H/D exchange for primary amide substituted $\mathbf{6 e}$ and phenyl amide substituted $\mathbf{8 1}$.

### 4.5 Conclusions

Rate constants for H/D exchange and hydrolysis of compounds $\mathbf{6 b}, \mathbf{d}, \mathbf{e}, 7 \mathbf{a}-\mathbf{d}$ and 8a-1 have been determined under aqueous conditions in phosphate buffers. Analysis of this data and comparison with the results and conclusions from Chapter 3, suggest the following conclusions.

First, rate constants of H/D exchange for compounds with an amide substituent on the stereogenic centre are much lower than those for analogous compounds with an ester substituent on the stereogenic centre. This supports the assignments of Testa et al. (Table 1.1), that designate an ester group as a stronger configurationally destabilising substituent than an amide. The low rate of $\mathrm{H} / \mathrm{D}$ exchange for compounds 6a-e at physiological pH and temperature suggests that stereogenic centres such as these are not at high risk of undergoing racemisation in the body under pharmacological timescales. However, the magnitude of the rate constants of $\mathrm{H} / \mathrm{D}$ exchange for 6a-e may be important in the synthesis or shelf-life of a drug based on a similar scaffold.

Second, evidence suggests that the mechanism of H/D exchange for the compounds analysed in this chapter is the $\mathrm{S}_{\mathrm{E}} 1$ mechanism. Hammett analysis of $\mathbf{6 b}, \mathbf{d}$, e and $\mathbf{8 a}, \mathbf{g}, \mathbf{i}, \mathbf{k}, \mathbf{l}$ shows similar levels of negative charge built up on the reaction centre during $H / D$ exchange as seen for 3a-1 in Chapter 3, for which an $\mathrm{S}_{\mathrm{E}} 1$ mechanism was deduced. Similarly, the thermodynamic activation parameters calculated for 6 e are consistent with the $\mathrm{S}_{\mathrm{E}} 1$ mechanism when compared to literature values.

Third, Arrhenius and Eyring plots of H/D exchange data for 6e have shown the potential for high-temperature work to be used for rapid screening to obtain approximate information on configurational instability at lower temperatures.

Fourth, Hammett analysis of compounds $\mathbf{7 a - d}$ and 8a-l illustrates how substituents several bonds away from the stereogenic centre can still have a large influence over the rate constant for $\mathrm{H} / \mathrm{D}$ exchange.

### 4.6 Experimental

### 4.6.1 General Experimental

All reagents were purchased from Acros Organics, Alfa Aesar, Fluorochem or Sigma-Aldrich.
${ }^{1} \mathrm{H}$ NMR and ${ }^{13} \mathrm{C}$ NMR spectra were recorded on a Bruker DPX 400 or DPX 500 spectrometer. HMBC and HSQC experiments were used on the same spectrometers to confirm assignments when necessary. $\delta$ values are reported in ppm downfield from trimethylsilane. LCMS experiments were performed using a Waters 2790 liquid chromatograph and a Waters ZQ mass spectrometer. Samples were loaded using a Gilson 232XL autosampler. Mass spectrometry data was processed using Waters MassLynx software and Waters QuanLynx software was used to analyse the data. Infrared spectra were obtained using a Varian 7000 FT-IR spectrometer. Samples were applied directly to the diamond tip. High-resolution mass spectra were obtained on a Waters LCT Premier XE mass spectrometer.

### 4.6.2 Synthesis of Compounds

### 4.6.2.1 Synthesis of Phenylglycine Amides 5a-e

Compounds 5a-e were synthesised from the appropriate phenylglycine methyl ester hydrochloride salts $\mathbf{2 a - l}$, the synthesis of which was described in the experimental to Chapter 3. The method was adapted from that used by Noorduin et al. (Scheme 4.11). ${ }^{26}$

Scheme 4.11: Synthesis of phenylglycine amides 5a-e.
The general method outlined below in the synthesis of $\mathbf{5 a}$ was used for the synthesis of all compounds 5a-e.

## Phenylglycine amide (5a)

Phenylglycine methyl ester hydrochloride salt ( $\mathbf{2 a}, 10 \mathrm{~g}, 49.6 \mathrm{mmol}$ ), was added to a solution of concentrated aqueous ammonia ( 35 ml ). The solution was stirred at room temperature for 5
hours. The solution was cooled to $0{ }^{\circ} \mathrm{C}$, and the precipitate was filtered and dried under reduced pressure to give phenylglycine amide as a white solid ( $6.21 \mathrm{~g}, 41.4 \mathrm{mmol}, 83 \%$ ).
${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{DMSO}$ ) $\delta=7.55\left(\mathrm{~s}, 1 \mathrm{H},-\mathrm{C}(\mathrm{O}) \mathrm{NH}_{\mathbf{a}} \mathrm{H}_{\mathrm{b}}\right), 7.26-7.46\left(\mathrm{~m}, 5 \mathrm{H},-\mathrm{C}_{6} \mathrm{H}_{6}\right), 7.10$ ( $\left.\mathrm{s}, 1 \mathrm{H},-\mathrm{C}(\mathrm{O}) \mathrm{NH}_{\mathrm{a}} \mathrm{H}_{\mathrm{b}}\right), 4.37\left(\mathrm{~s}, 1 \mathrm{H},-\mathrm{CH}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)\right.$ ).
${ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{DMSO}$ ) $\delta=175.37\left(1 \mathrm{C},-\mathrm{C}(\mathrm{O}) \mathrm{NH}_{2}\right), 142.79$ ( 1 C , ipso aromatic carbon), 128.40 ( 2 C , meta aromatic carbon), 127.36 ( 1 C , para aromatic carbon), 127.12 ( 2 C , ortho aromatic carbon), $59.01\left(1 \mathrm{C},-\mathrm{CH}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)-\right)$.

IR (ss) $\mathrm{v} / \mathrm{cm}^{-1}: 3381,3279,1681$
Found $\mathrm{m} / \mathrm{z}\left(\mathrm{AP}^{+}\right)=151.0865$, calculated 151.0871
M.p. $=140-141^{\circ} \mathrm{C}$

## ( $p$-Methyl phenyl) glycine amide (5b)

Synthesised from compound 2c. Yield: 72 \%
${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{DMSO}$ ) $\delta=7.46\left(\mathrm{~s}, 1 \mathrm{H},-\mathrm{C}(\mathrm{O}) \mathrm{NH}_{\mathrm{a}} \mathrm{H}_{\mathrm{b}}\right.$ ), 7.28 (d, 2 H , aromatic protons meta to methyl, $\left.{ }^{3} J_{\mathrm{H}-\mathrm{H}}=7.92 \mathrm{~Hz}\right), 7.11\left(\mathrm{~d}, 2 \mathrm{H}\right.$, aromatic protons ortho to methyl, ${ }^{3} J_{\mathrm{H}-\mathrm{H}}=7.84$ $\mathrm{Hz}), 7.03\left(\mathrm{~s}, 1 \mathrm{H},-\mathrm{C}(\mathrm{O}) \mathrm{NH}_{\mathrm{a}} \mathbf{H}_{\mathrm{b}}\right), 4.25\left(\mathrm{~s}, 1 \mathrm{H},-\mathrm{CH}\left(\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{CH}_{3}\right)-\right.$ ), $2.27\left(\mathrm{~s}, 3 \mathrm{H},-\mathrm{CH}_{3}\right)$.
${ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{DMSO}$ ) $\delta=175.57\left(1 \mathrm{C},-\mathrm{C}(\mathrm{O}) \mathrm{NH}_{2}\right), 139.92$ ( 1 C , aromatic carbon para to methyl), 136.36 ( 1 C , aromatic carbon ipso to methyl), 128.92 ( 2 C , aromatic carbon ortho to methyl), 126.98 ( 2 C , aromatic carbon meta to methyl), 59.01 ( $1 \mathrm{C},-\mathrm{CH}\left(\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{CH}_{3}\right)$ ), 21.03 ( $1 \mathrm{C},-\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{CH}_{3}$ ).

### 4.6.2.2 Synthesis of $N$-Acetyl Phenylglycine Amides 6a-e

Compounds 6a-e were synthesised from phenylglycine amides 5a-e (Scheme 4.12).

Scheme 4.12: Synthesis of $N$-acetyl phenylglycine amides 6a-e.
The general method outlined below in the synthesis of $\mathbf{6 a}$ was used for the synthesis of all compounds 6a-e.

## $N$-Acetyl phenylglycine amide (6a)

Phenylglycine amide ( $\mathbf{5 a}, 0.5 \mathrm{~g}, 3.33 \mathrm{mmol}$ ) was suspended in anhydrous DCM ( 30 ml ) under a nitrogen atmosphere. Triethylamine ( 1.2 equiv., $4 \mathrm{mmol}, 0.56 \mathrm{ml}$ ) was added, and the mixture stirred for 30 mins . Acetyl chloride ( 1.2 equivs., $4 \mathrm{mmol}, 0.29 \mathrm{ml}$ ) was added and the mixture left to stir for a further three hours, before being evaporated to dryness. The residue was washed with a small quantity of ice-cold water, before being dried under reduced pressure to give $N$-acetyl phenylglycine amide as a white solid ( $0.49 \mathrm{~g}, 2.55 \mathrm{mmol}, 77 \%$ ).
${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{DMSO}$ ) $\delta=8.48\left(\mathrm{~d}, 1 \mathrm{H},-\mathrm{NH}-,{ }^{3} J_{\mathrm{H}-\mathrm{H}}=8.12 \mathrm{~Hz}\right), 7.68(\mathrm{~s}, 1 \mathrm{H},-$ $\left.\mathrm{C}(\mathrm{O}) \mathrm{NH}_{\mathbf{a}} \mathrm{H}_{\mathrm{b}}\right), 7.27-7.42\left(\mathrm{~m}, 5 \mathrm{H},-\mathrm{C}_{6} \mathrm{H}_{5}\right), 7.13\left(\mathrm{~s}, 1 \mathrm{H},-\mathrm{C}(\mathrm{O}) \mathrm{NH}_{\mathrm{a}} \mathrm{H}_{\mathrm{b}}\right), 5.39\left(\mathrm{~d}, 1 \mathrm{H},-\mathrm{CH}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)-\right.$, $\left.{ }^{3} J_{\mathrm{H}-\mathrm{H}}=8.12 \mathrm{~Hz}\right), 1.89\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{CH}_{3} \mathrm{C}(\mathrm{O})-\right)$.
${ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{d}^{6}$-DMSO) $\delta=172.17$ ( $1 \mathrm{C}, \mathrm{CH}_{3} \mathrm{C}(\mathrm{O})-$ ), $169.18\left(1 \mathrm{C},-\mathbf{C}(\mathrm{O}) \mathrm{NH}_{2}\right), 139.59$ ( 1 C , aromatic), 128.56 ( 2 C , aromatics), 127.72 ( 1 C , aromatic), 127.45 ( 2 C , aromatics), 56.37 ( $1 \mathrm{C},-\mathbf{C H}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)-$ ), $22.81\left(1 \mathrm{C},-\mathrm{C}(\mathrm{O}) \mathrm{CH}_{3}\right)$.

### 4.6.2.3 Synthesis of $N$-Benzoyl Phenylglycine Amides 7a-d

Compounds 7a-d were synthesised from phenylglycine amide 5a (Scheme 4.13).

5a

7a-d

Scheme 4.13: Synthesis of $N$-benzoyl phenylglycine amides 7a-d.
The general method outlined below in the synthesis of $7 \mathbf{a}$ was used for the synthesis of all compounds $7 \mathbf{7 a}$-d.

## $N$-Benzoyl phenylglycine amide (7a)

Phenylglycine amide ( $\mathbf{5 a}, 0.5 \mathrm{~g}, 3.33 \mathrm{mmol}$ ) was suspended in anhydrous DCM ( 30 ml ) under a nitrogen atmosphere. Triethylamine ( 1.2 equiv., $4 \mathrm{mmol}, 0.56 \mathrm{ml}$ ) was added, and the mixture stirred for 30 mins. Benzoyl chloride ( 1.2 equivs., $4 \mathrm{mmol}, 0.29 \mathrm{ml}$ ) was added and the mixture left to stir for a further three hours, before being evaporated to dryness. The residue was triturated with water and filtered. The residue was washed on the filter with water, then with 1 M HCl , water, saturated $\mathrm{NaHCO}_{3}$ solution, water and finally with diethyl ether before being dried under reduced pressure to give $N$-benzoyl phenylglycine amide as a white solid ( $0.73 \mathrm{~g}, 2.87 \mathrm{mmol}, 86 \%$ ).
${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{DMSO}$ ) $\delta=8.73\left(\mathrm{~d}, 1 \mathrm{H},-\mathrm{NH}-,{ }^{3} J_{\mathrm{H}-\mathrm{H}}=7.96 \mathrm{~Hz}\right), 7.92(\mathrm{~d}, 2 \mathrm{H}$, ortho benzoyl aromatic protons, $\left.{ }^{3} J_{\mathrm{H}-\mathrm{H}}=7.08 \mathrm{~Hz}\right), 7.71\left(\mathrm{~s}, 1 \mathrm{H},-\mathrm{C}(\mathrm{O}) \mathrm{NH}_{\mathrm{a}} \mathrm{H}_{\mathrm{b}}\right), 7.28-7.56(\mathrm{~m}, 8 \mathrm{H}$, meta and para benzoyl aromatic protons and phenylglycine aromatic protons), $7.26(\mathrm{~s}, 1 \mathrm{H},-$ $\left.\mathrm{C}(\mathrm{O}) \mathrm{NH}_{\mathrm{a}} \mathbf{H}_{\mathrm{b}}\right), 5.63\left(\mathrm{~d}, 1 \mathrm{H},-\mathrm{CH}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)-,{ }^{3} J_{\mathrm{H}-\mathrm{H}}=7.96 \mathrm{~Hz}\right)$.
${ }^{13} \mathrm{C}$ NMR ( $\left.125 \mathrm{MHz}, \mathrm{DMSO}\right) ~ \delta=171.63\left(1 \mathrm{C},-\mathrm{C}(\mathrm{O}) \mathrm{NH}_{2}\right), 165.89\left(1 \mathrm{C},-\mathrm{C}(\mathrm{O}) \mathrm{C}_{6} \mathrm{H}_{5}\right), 138.78$ ( 1 C , ipso phenylglycine aromatic carbon), 133.96 ( 1 C , ipso benzoyl aromatic carbon), 131.35 (1C, para benzoyl aromatic carbon), 128.21 ( 2 C , meta benzoyl aromatic carbon), 128.18 ( 2 C , meta phenylglycine aromatic carbon), 127.54 ( 2 C , ortho benzoyl aromatic carbon), 127.47 (1C, para phenylglycine aromatic carbon), 127.43 ( 2 C , ortho phenylglycine aromatic carbon), $56.80\left(1 \mathrm{C},-\mathrm{CH}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)\right.$-).

IR (ss) $v / \mathrm{cm}^{-1}: 3370,3255,3164,1660,1636,1520$

### 4.6.2.4 Synthesis of $N$-Acetyl Phenylglycine Anilides 8a-I

Compounds 8a-l were synthesised from the corresponding $N$-acetyl phenylglycines $\mathbf{4 a}, \mathbf{c - e}, \mathbf{g}$ $\mathbf{h}$, the synthesis of which is described in the experimental to chapter 3. The method was adapted from that used by Hyun et al. (Scheme 4.14). ${ }^{27}$

4

8

Scheme 4.14: Synthesis of $N$-acetyl phenylglycine anilides 8a-l.
The general method outlined below in the synthesis of $\mathbf{8 a}$ was used for the synthesis of all compounds 8a-l. Assignments of ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra were made with the aid of 2D spectra (HSQC and HMBC) and the use of approximate substituent chemical shift tables by Williams and Fleming. ${ }^{28}$

## 2-Acetamido-2-phenyl acetanilide (8a)

To a stirred suspension of $N$-acetyl phenylglycine ( $4 \mathrm{a}, 0.5 \mathrm{~g}, 2.6 \mathrm{mmol}$ ) in DCM ( 35 ml ) was added aniline ( 1.1 equiv., $0.3 \mathrm{ml}, 3.0 \mathrm{mmol}$ ) and 2-ethoxy-1-ethoxycarbonyl-1,2dihydroquinoline (EEDQ) ( 1.1 equiv., $0.74 \mathrm{~g}, 3.0 \mathrm{mmol}$ ). The mixture was stirred at room temperature overnight and then washed with $0.5 \mathrm{M} \mathrm{HCl}, 0.5 \mathrm{M} \mathrm{NaOH}$ and brine and then dried with magnesium sulphate. The solvent was removed and the product was washed with ethyl acetate to give 2-acetamido-2-phenyl acetanilide ( $0.30 \mathrm{~g}, 1.2 \mathrm{mmol}, 43 \%$ ) as a white solid.
${ }^{1} \mathrm{H}$ NMR ( $\left.500 \mathrm{MHz}, \mathrm{d}^{6}-\mathrm{DMSO}\right) \delta=10.37\left(\mathrm{~s}, 1 \mathrm{H},-\mathrm{NH}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)\right), 8.71\left(\mathrm{~d}, 1 \mathrm{H},-\mathrm{NHAc},{ }^{3} J_{\mathrm{H}-\mathrm{H}}=\right.$ $7.85 \mathrm{~Hz}), 7.60\left(\mathrm{~d}, 2 \mathrm{H}\right.$, ortho anilide aromatic protons, $\left.{ }^{3} J_{\mathrm{H}-\mathrm{H}}=7.70 \mathrm{~Hz}\right), 7.50(\mathrm{~d}, 2 \mathrm{H}$, ortho phenylglycine aromatic protons, $\left.{ }^{3} J_{\mathrm{H}-\mathrm{H}}=7.40 \mathrm{~Hz}\right), 7.38(\mathrm{t}, 2 \mathrm{H}$, meta phenylglycine aromatic protons, $\left.{ }^{3} J_{\mathrm{H}-\mathrm{H}}=7.30 \mathrm{~Hz}\right), 7.31\left(\mathrm{t}, 1 \mathrm{H}\right.$, para phenylglycine aromatic proton, $\left.{ }^{3} J_{\mathrm{H}-\mathrm{H}}=7.20 \mathrm{~Hz}\right)$, $7.30\left(\mathrm{t}, 2 \mathrm{H}\right.$, meta anilide aromatic protons, $\left.{ }^{3} J_{\mathrm{H}-\mathrm{H}}=8.00 \mathrm{~Hz}\right), 7.05(\mathrm{t}, 1 \mathrm{H}$, para anilide aromatic proton, $\left.{ }^{3} J_{\mathrm{H}-\mathrm{H}}=7.40 \mathrm{~Hz}\right), 5.66\left(\mathrm{~d}, 1 \mathrm{H},-\mathrm{CH}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)-{ }^{3} J_{\mathrm{H}-\mathrm{H}}=7.90 \mathrm{~Hz}\right), 1.94\left(\mathrm{~s}, 3 \mathrm{H},-\mathrm{COCH}_{3}\right)$.

### 4.6.3 Proton-Deuterium Exchange Reactions

### 4.6.3.1 ${ }^{1} \mathrm{H}$ NMR Experiments at $37{ }^{\circ} \mathrm{C}$

The H/D exchange reactions of $6 \mathbf{e}$ at $37^{\circ} \mathrm{C}$, described in Section 4.4.1.1, were monitored by ${ }^{1} H$ NMR spectroscopy. These experiments were carried out according to the method described in the experimental to Chapter 3, with the exception that no hydrolysis occurs for 6e. Therefore, there is no drop in pH and hence no need to maintain the $\mathrm{pH}^{* *}$ with addition of NaOD solution.

### 4.6.3.2 LCMS Experiments at 60, 70, 80 and $90{ }^{\circ} \mathrm{C}$

Buffers for H/D exchange experiments were made according to the following method. The appropriate quantity of $\mathrm{NaH}_{2} \mathrm{PO}_{4}$ for the desired buffer concentration was dissolved in $\mathrm{D}_{2} \mathrm{O}$. The ionic strength was made to 1 M using NaCl . As $\mathrm{p} K_{\mathrm{a}}$ varies with temperature, the required
$\mathrm{pH}^{*}$ of the solution at room temperature, was calculated so that the desired $\mathrm{pH}^{*}$ at temperatures of $60,70,80$ and $90{ }^{\circ} \mathrm{C}$ was obtained. This temperature-corrected $\mathrm{pH}^{*}$ was obtained through adding portions of $\mathrm{NaOD} / \mathrm{D}_{2} \mathrm{O}$ solution whilst monitoring with a pH probe at $25^{\circ} \mathrm{C}$. The $\mathrm{pH}^{*}$ was also measured at the temperature at which the buffer was to be used in order to confirm it was at the desired value at this temperature.

H/D exchange kinetic experiments were carried out in duplicate, using a liquid chromatograph with mass spectrometer detection. Before analysis, calibration curves were produced for the mass spectrometer response of each compound for analysis. Starting with initial concentrations of $9-10 \mu \mathrm{M}$, these were subsequently diluted four times, each time by a dilution factor of four to produce five solutions with a range of concentrations down to $<0.1$ $\mu \mathrm{M}$. These solutions were then analysed using the mass spectrometer, with detection at the appropriate mass to find the $\mathrm{M}+1$ molecular ion. A linear response was obtained for each compound $\mathbf{6 b}, \mathbf{d}, \mathbf{e}, \mathbf{7 a - d}$ and $\mathbf{8 a - l}$. To initiate each experiment, the autosampler injected a 10 $\mu \mathrm{l}$ portion from a stock solution of compound dissolved in acetonitrile into 1 ml of the appropriate buffer solution. The buffer solution was preheated to the appropriate temperature in a thermostatted vial tray, from where injections were made at the desired (preprogrammed) times. After each injection, the mass spectrogram was automatically analysed. The integral was converted to the concentration of compound protonated at the stereogenic centre using the calibration curve. To ensure that $\mathrm{H} / \mathrm{D}$ exchange was the only process resulting in loss of the original molecular ion, in each case a control sample of the substrate in $\mathrm{H}_{2} \mathrm{O} 0.3 \mathrm{M}$ phosphate buffer solution was also analysed. As the mass spectrometer response for the $\mathrm{M}+1$ ion of this sample did not reduce over time for any of the compounds analysed, it is safe to assume that the only process resulting in a reduction in the response of the $\mathrm{M}+1$ ion is $\mathrm{H} / \mathrm{D}$ exchange. For compound $\mathbf{6 e}$, a sample was left in deuterated buffers at $90^{\circ} \mathrm{C}$ for 2 days to ensure all compound was deuterated at the stereogenic centre. This sample was then diluted four-fold, four times and used to produce a calibration curve with detection of the $\mathrm{M}+2$ molecular ion. Formation of this species was followed at $60^{\circ} \mathrm{C}$, simultaneous with monitoring the decrease in the response for the $\mathrm{M}+1$ molecular ion. These curves are plotted together in Figure 4.17.

Experiments were carried out using an XTerra column (MS C18 $2.5 \mathrm{~mm}, 2.1 \times 30 \mathrm{~mm}$ : part no. 186000592). Flow rate was 0.7 ml per minute. The eluents and the gradient used in the LC method are as follows:

Channel $\mathrm{A}=5 \% \mathrm{CH}_{3} \mathrm{CN}, 10 \mathrm{mM} \mathrm{NH}_{4} \mathrm{OAc}, 0.1 \%$ Acetic acid ( $\mathrm{pH}=4.5$ ), Channel $\mathrm{B}=95 \%$ $\mathrm{CH}_{3} \mathrm{CN}, 0.05 \%$ Acetic acid.

Table 4.15: Gradient used for Chapter 4 LCMS experiments.

| Time (mins) | \% A | \% B |
| :---: | :---: | :---: |
| 0.0 | 100 | 0 |
| 6.0 | 0 | 100 |
| 10.0 | 0 | 100 |
| 10.1 | 100 | 0 |
| 14.0 | 100 | 0 |

The data obtained from the kinetic experiments was plotted using OriginPro 8. Observed firstorder rate constants were obtained through fitting the data to eqn (3.6). Figure 4.9 was plotted using Wolfram Mathematica 8.0.

### 4.7 Appendix

### 4.7.1 Figures from ${ }^{1} H$ NMR Kinetic Experiments

The graphs from which the rate constants of H/D exchange for compound $\mathbf{6 e}$ in Table 4.2 were determined are displayed in Figure 4.11. All experiments were carried out at $37^{\circ} \mathrm{C}, I=1$ M. $\mathrm{pH}^{* *} 7.4$.

Figure 4.11: H/D exchange data for compound 6 e at $37^{\circ} \mathrm{C}, \mathrm{pH}^{* *} 7.4, I=1$ M. Phosphate buffer concentration a) $0.1 \mathrm{M}, \mathrm{b}) 0.2 \mathrm{M}, \mathrm{c}) 0.3 \mathrm{M}$.

### 4.7.2 Data Tables from LCMS Kinetic Experiments

The LCMS experimental data from which Figure 4.2 and Figure 4.4 were constructed is listed in the tables displayed in the following pages.

Table 4.16: Rate constant data for compound $\mathbf{6 b}$ in $\mathrm{D}_{2} \mathrm{O}$ buffers of $\mathrm{pH}^{*} 7.4$ at $90^{\circ} \mathrm{C}, I=1 \mathrm{M}$.

Figure 4.19: $\mathrm{H} / \mathrm{D}$ exchange data for at $90^{\circ} \mathrm{C}, 0.3 \mathrm{M}$ phosphate buffer concentration for a) $\mathbf{8 a}$, b) $\mathbf{8 a}$ (duplicate), c) $\mathbf{8 b}$, d) $\mathbf{8 b}$ (duplicate), e) $\mathbf{8 c}$, f) 8c (duplicate), g) 8d, h) 8d (duplicate).

Figure 4.20: H/D exchange data for at $90^{\circ} \mathrm{C}, 0.3 \mathrm{M}$ phosphate buffer concentration for a) $\mathbf{8 e}$, b) $\mathbf{8 e}$ (duplicate), c) $\mathbf{8 f}$, d) $\mathbf{8 f}$ (duplicate), e) $\mathbf{8 g}$, f) $\mathbf{8 g}$ (duplicate), g) $\mathbf{8 h}, \mathrm{h}) \mathbf{8 h}$ (duplicate).

Figure 4.21: H/D exchange data for at $90^{\circ} \mathrm{C}, 0.3 \mathrm{M}$ phosphate buffer concentration for a) $\mathbf{8 i}$, b) $\mathbf{8 i}$ (duplicate), c) $\mathbf{8 j}$, d) $\mathbf{8 j}$ (duplicate), e) $\mathbf{8 k}$, f) $\mathbf{8 k}$ (duplicate), g) 81, h) 81 (duplicate).

### 4.7.3.9 Eyring Plot for Use as a Predictive Tool

As discussed in Section 4.4.1.4, an Eyring plot was constructed of using the data in Table 4.6 of rate constants of general-base catalysed H/D exchange, omitting the data point obtained using ${ }^{1} \mathrm{H}$ NMR spectroscopy at $37{ }^{\circ} \mathrm{C}$. This was for the purpose of analysing the use of hightemperature work as a predictive tool for lower temperatures. The Eyring plot constructed is shown in Figure 4.22.

Figure 4.22: Eyring plot of general-base catalysed H/D exchange of 6e (without data point at $37^{\circ} \mathrm{C}$ ), in $\mathrm{D}_{2} \mathrm{O}$ phosphate buffers at $\mathrm{pH}^{*} 7.4, I=1 \mathrm{M}$. $y$-axis intercept $=\ln \left(k_{\mathrm{B}} / h\right)+\Delta S^{\ddagger} / R=14.86 \pm 3.03$. Gradient $=-\Delta H^{\ddagger} / R=-$ $9701.09 \pm 1075.72$.

The line of best fit shown in Figure 4.22 was extrapolated to $37^{\circ} \mathrm{C}$, and the expected value for $k_{\mathrm{gb}}$ was calculated as $2.39 \times 10^{-5} \mathrm{~s}^{-1} \mathrm{M}^{-1}$.

## 5 Computational Studies as a Predictive Tool for Configurational Instability

### 5.1 Introduction

In this Chapter, the potential of computational chemistry methods to predict configurational instability in molecules (under the pharmacological conditions such as those used in Chapters 3 and 4) is investigated. The ability to obtain approximate rate constants of racemisation for molecules under investigation as a potential drug, without having to undertake the physical experimental procedures described in Chapters 3 and 4 or without synthesising a compound, would be of substantial benefit to the pharmaceutical industry. The results from computational modelling of a molecule could either eliminate or necessitate the need for further experimental analysis. If a computational model can be found that correlates with the rate constants of H/D exchange determined in Chapters 3 and 4, then application of that model to other compounds of interest could give theoretical rate constants for $\mathrm{H} / \mathrm{D}$ exchange (and therefore for racemisation).

The rate constants of H/D exchange determined thus far have been for molecules of the type R''R'RC-H, and the reaction was found to take place through an $\mathrm{S}_{\mathrm{E}} 1$ mechanism (Chapter 3). As shown in Scheme 1.7, the $\mathrm{S}_{\mathrm{E}} 1$ mechanism takes place through loss of the labile proton bound to the stereogenic centre to leave a planar carbanion which can then be deuterated on either face (resulting in the loss of any enantiopurity). The stability of this carbanion is strongly dependent on the nature of neighbouring groups, specifically their ability to stabilise the negative charge either through delocalisation or electrostatic interactions. The results in Chapters 3 and 4 show that the stability of this carbanion is fundamental to the rate constant of H/D exchange, illustrated by the positive slope displayed in Hammett plots. Therefore, it was the stability of the carbanion, relative to the protonated state, that was investigated through computational methods. This relative stability is indicated by $\Delta G^{\Theta}$ in the reaction profile for the $\mathrm{S}_{\mathrm{E}} 1$ mechanism (Figure 5.1).

Figure 5.1: Reaction profile for $\mathrm{H} / \mathrm{D}$ exchange through the $\mathrm{S}_{\mathrm{E}} 1$ mechanism, where $\Delta G^{\ominus \ddagger}$ is the standard molar free energy of activation and $\Delta G^{\ominus}$ is the standard molar free energy of reaction.

Nakata et al. used computational methods to investigate the stability of benzylic anions in the gas-phase. ${ }^{1}$ The energies and geometries of ring substituted anions and the corresponding neutral species were calculated using the B3LYP/6-311 $+\mathrm{G}(2 \mathrm{~d}, \mathrm{p})$ level of theory. The substituent effects of on the relative stability of the anions was then determined through hypothetical proton transfer reactions (Scheme 5.1).

Scheme 5.1: Proton transfer reactions analysed by Nakata et al.
$\Delta E_{\mathrm{X}}$ was calculated for the reaction depicted in Scheme 5.1, via equation (5.1).

$$
\begin{equation*}
\Delta E_{\mathrm{X}}=\left[E_{\mathrm{H}}(\mathrm{H})+E_{\mathrm{X}}(-)\right]-\left[E_{\mathrm{H}}(-)+E_{\mathrm{X}}(\mathrm{H})\right] \tag{5.1}
\end{equation*}
$$

with $E_{\mathrm{S}}(\mathrm{Y})$ the calculated energy of the species with substituent S on aromatic ring, and Y describing the protonation state at the benzylic position. $\Delta E_{\mathrm{X}}$ denotes the calculated stability of the substituted benzylic anion with respect to the unsubstituted benzylic anion.

Electron-withdrawing aromatic substituents were found to stabilise a negative charge relative to the unsubstituted benzylic anion. The authors analysed their results in terms of an extended Yukawa-Tsuno equation, and found that resonance and saturation effects ${ }^{2,3}$ were present alongside the fundamental inductive effect.

A method of investigation similar to that of Nakata et al. was employed in this chapter. For all compounds under investigation, the standard molar Gibbs energy of the compound was calculated both for the protonated and deprotonated (at the stereogenic centre) form. The difference in these values for individual compounds does not mean anything in itself, as the loss of a proton from one species to the other makes direct comparison impossible. However, when compared with the values obtained in the same manner for other compounds, it can be assumed that all errors involved in the calculations cancel out (as in the example from Nakata et al. illustrated in Scheme 5.1). Hence, if carbanion stability is an important factor in determining H/D exchange rates and the calculations are performed at a sufficient level of accuracy, a correlation between the calculated energy difference of the two protonation states with the rate constants of $\mathrm{H} / \mathrm{D}$ exchange calculated in Chapters 3 and 4 should be obtainable. If such a correlation is be found, the relationship could be used to predict rate constants of H/D exchange and racemisation from calculated energies of molecules of interest. In essence, the proposed link between anion stability and the rate constant for racemisation is a linear free energy relationship.

The rate of deprotonation at the stereogenic centre is dependent on $\Delta G^{\ominus \ddagger}$ (see Figure 5.1). However, the Hammond Postulate ${ }^{4,5}$ suggests that if the energy difference between protonation states is lowered by changes to the molecular scaffold, i.e. through greater stabilisation of negative charge, the energy of the activated complex should also be reduced. This is illustrated in Figure 5.2.

## Reaction Coordinate

Figure 5.2: Reaction profile for proton abstraction by base. Reactants AH and A'H (in their protonated states) set at same molar free energy. The base, $B^{-}$, is the same in both reactions.

The structural modification of A to A ' results in stabilisation of the negative charge in the anionic product. According to the Hammond postulate, this structural modification will also stabilise the transition state (relative to the unmodified structure) in the same manner (although not necessarily to the same extent), by delocalisation of the negative charge built up on the transition state during proton abstraction. The relationship between $\delta \Delta G^{\ominus \dagger}$ and $\Delta G^{\Theta}$ is typically quantified using the Brønsted relationship (Section 1.8.1).

Calculating the energy difference between the compound in its protonated and deprotonated (at the stereogenic centre) states gives a value related to $\Delta G^{\ominus}$, the real difference in energy between the two protonation states. This calculated value will include errors resultant from changes in the number of atoms in the calculation as well as limitations in the level of theory used (including solvation), and shall be referred to as ' $\Delta G^{\theta^{*}}$. We assume that the remaining ${ }^{\dagger}$ theory-specific errors in calculated energies are consistent between structures being investigated and cancel out, as illustrated in Figure 5.3.

[^18]

Increasing Anion Stability

Figure 5.3: $\Delta G^{\Theta^{*}}$ as anion stability increases with modification of molecular structure. ( $\mathbf{\omega}$ ) Portion of $\Delta G^{\theta^{*}}$ due to errors in calculation, ( $\quad$ ) portion of $\Delta G^{\theta^{*}}$ resulting from molecular structure. Contributions not to scale.

Figure 5.3 illustrates that, although the size of the errors will be unknown, these errors are anticipated to cancel out upon subtraction of $\Delta G^{\theta^{*}}$ for one compound from that calculated for another. This procedure should thus afford $\delta \Delta G^{\ominus}$ with acceptable residual errors (see Figure 5.2). It should then be possible to correlate this value with the rate constants of H/D exchange determined in Chapters 3 and 4.

### 5.2 Results

Calculations were undertaken on all species from Chapters 3 and 4 for which rate constants of $\mathrm{H} / \mathrm{D}$ exchange as a function of basic buffer concentration $\left(k_{\mathrm{gb}}\right)$ had been determined at $\mathrm{pH}^{* *}$ 7.4 at $37^{\circ} \mathrm{C}$. These were compounds $\mathbf{3 a - h}, \mathbf{3 k}-1$ and $\mathbf{6 e}$ (Scheme 5.2).

3k

31

Scheme 5.2: Structures for which computational analysis was performed.
Calculations were performed on each structure, for both species, ${ }^{\ddagger}$ i.e. protonated and deprotonated at the stereogenic centre. All calculations in this chapter were performed using density functional theory (DFT, cf. Section 1.10.4) at the RB3LYP/6-31 $+\mathrm{G}(\mathrm{d}, \mathrm{p}$ ) level of theory, with the geometry optimised prior to frequency calculations being performed. Each calculation was performed both in the gas-phase and with an aqueous solvent modelled using the polarisable continuum method (PCM, cf. Section 1.10.4). Calculations were performed on each species of each compound, with a range (minimum of 4) of starting geometries prior to optimisation. These starting geometries were proposed largely based on 'chemical intuition' i.e. conformations that appear to be good candidates for the most stable structure. Using several different starting geometries gives optimised structures of a range of configurations.

[^19]The optimised geometry with the lowest energy in each case was used for correlation analysis.

### 5.2.1 Results from Calculations Employing PCM

For each structure on which calculations were performed, the calculated energy differences between the two protonation states, $\Delta G^{\Theta^{*}}$, and the calculated energy differences between the two protonation states relative to compound $\mathbf{3 a}, \delta \Delta G^{\ominus}$, are displayed in Table 5.1.

Table 5.1: $\Delta G^{\theta^{*}}$ and $\delta \Delta G^{\theta}$ of $\mathbf{3 a - h}, \mathbf{3 k}-\mathrm{l}$ and $\mathbf{6 e}$, from calculated energies of each structure in both protonation states, using the PCM. ${ }^{\text {a }}$

| Compound | $\Delta G^{\boldsymbol{\theta}^{\boldsymbol{x}}} / \mathrm{kJ} \mathrm{mol}^{-1}$ | $\boldsymbol{\delta} \Delta \boldsymbol{G}^{\boldsymbol{\theta b}} / \mathrm{kJ} \mathrm{mol}^{-1}$ |
| :---: | :---: | :---: |
| 3a | 1270.253 | 0.000 |
| 3b | 1277.833 | 7.580 |
| 3 c | 1273.848 | 3.594 |
| 3d | 1269.718 | -0.536 |
| 3 e | 1264.504 | -5.750 |
| 3 f | 1259.975 | -10.279 |
| 3g | 1257.667 | -12.587 |
| 3h | 1250.814 | -19.440 |
| 3k | 1245.821 | -24.433 |
| 31 | 1263.650 | -6.603 |
| 6 e | 1268.447 | -1.806 |

[^20]The calculated $\delta \Delta G^{\Theta}$ in Table 5.1 were then used for correlation analysis with the experimental rate constant data, and with Hammett substituent constants.

### 5.2.1.1 Correlation with Experimentally Determined $\boldsymbol{k}_{g b}$

The rate constants for general-base catalysed $\mathrm{H} / \mathrm{D}$ exchange ( $k \mathrm{gb}$, from Tables 3.2, 3.7 and 4.3) were plotted against $\delta \Delta G^{\ominus}$ (from Table 5.1) for methyl esters $\mathbf{3 a - h}, \mathbf{3 k}-\mathbf{l}$ and primary amide $\mathbf{6 e}$ (Figure 5.4).

Figure 5.4: Correlation of $\delta \Delta G^{\ominus}$ (using PCM) with $\log k_{\mathrm{gb}}$ (determined at $37^{\circ} \mathrm{C}, I=1 \mathrm{M}$ ) for (■) 3a-h, 3k-I and ( $\left.\mathbf{\Delta}\right) \mathbf{6 e} \cdot \mathrm{R}^{2}=0.968$ (fitted to (■) only).

Figure 5.4 shows a clear correlation for $\log k_{\mathrm{gb}}$ with $\delta \Delta G^{\theta}$ for methyl esters 3a-h, $\mathbf{k}-\mathbf{l}$. As $\delta \Delta G^{\theta}$ increases, the rate constant of H/D exchange becomes smaller accordingly. The straight line displayed in Figure 5.4 is compatible with a common mechanism of H/D exchange for methyl ester compounds $\mathbf{3 a} \mathbf{- h}, \mathbf{k} \mathbf{l}$, with proton abstraction as the rate-determining step. The correlation between $\delta \Delta G^{\ominus}$ and $\log k_{\mathrm{gb}}$ therefore supports the proposed $\mathrm{S}_{\mathrm{E}} 1$ mechanism for H/D exchange in compounds 3a-h, k-l.

The calculated $\delta \Delta G^{\theta}$ for primary amide 6 e does not quite fit the trend displayed by methyl esters $\mathbf{3 a} \mathbf{a} \mathbf{h}$, $\mathbf{k}-\mathbf{I}$. The $\delta \Delta G^{\theta}$ value obtained for this compound suggests a slightly faster rate constant of general-base catalysed H/D exchange than that obtained experimentally in Chapter 4. However, the rate constant 'predicted' through computations is not too far off that obtained experimentally, less than an order of magnitude. This suggests that the general correlation between calculated $\delta \Delta G^{\ominus}$ and $k_{\mathrm{gb}}$ can be extended to a range of 'scaffolds', and hence suggests its potential for use as a predictive tool. Limitations to its applicability will be discussed later.

### 5.2.1.2 Hammett Analysis of Computational Data

The data displayed in Table 5.1 was plotted (Figure 5.5) as a function of the Hammett $\sigma^{-}$values for $\mathbf{3 a} \mathbf{- h}$ (from Table 1.5) and $\sigma$-values for $\mathbf{3 k} \mathbf{k}$ (from Table 1.8).

Figure 5.5: Hammett analysis of calculated $\delta \Delta G^{\ominus}$ for 3a-h and 3k-I correlated with $\sigma^{-}$-constants. $\mathrm{R}^{2}=0.979$.

Figure 5.5 shows a good correlation between $\delta \Delta G^{\Theta}$ and the Hammett $\sigma^{-}$-constants. These results also support the heterocyclic Hammett constants of 0.72 and 0.12 for the thiophene derivatives $\mathbf{3 k}$ and $\mathbf{3 1}$ respectively. This suggested that the computational data could be used to analyse proposed Hammett substituent constants for other heterocycles.

### 5.2.1.3 Analysis of Heterocyclic Substituent Constants

As discussed in Section 1.8.2.4, there have been a range of different Hammett constants suggested for individual heterocyclic groups, many of which are contradictory. Inspired by the good correlation between $\sigma^{-}$and $\delta \Delta G^{\ominus}$ (Figure 5.5), calculations were performed on the furan-, pyrrole- and pyridine-containing compounds $\mathbf{3 m - 0}$ (Scheme 5.3), to assess the accuracy of the Hammett constants proposed for these structures (Table 1.8).

Scheme 5.3: Structures 3m-o.

The lowest calculated energy for each species of each structure and the calculated $\delta \Delta G^{\ominus}$ for compounds $\mathbf{3 m - o}$ are given in Table 5.2.
Table 5.2: $\Delta G^{\ominus^{*}}$ and $\delta \Delta G^{\Theta}$ of $\mathbf{3 m - 0}$, from calculated energies of each structure in both protonation states, using the PCM. ${ }^{\text {a }}$

| Compound | $\Delta G^{\theta^{*}} / \mathrm{kJ} \mathrm{mol}^{-1}$ | $\boldsymbol{\delta} \Delta \boldsymbol{G}^{\boldsymbol{\theta} \mathbf{b}} / \mathrm{kJ} \mathrm{mol}^{-1}$ |
| :---: | :---: | :---: |
| 3m | 1262.193 | -8.060 |
| 3n | 1268.158 | -2.095 |
| 30 | 1238.947 | -31.306 |

${ }^{\text {a }}$ Number of decimal places carried through from Gaussian output.
${ }^{\mathrm{b}}$ Relative to compound 3a.
The correlation between $\delta \Delta G^{\ominus}$ and $\sigma$ (Figure 5.5) was used to calculate $\sigma$-values for furan, pyrrole and pyridine heterocycles, from the values calculated for $\delta \Delta G^{\theta}$ of $\mathbf{3 m - o}$ displayed in Table 5.2. These 'predicted' heterocyclic $\sigma$-values are compared with those from literature (Table 1.8) in Table 5.3.

Table 5.3: Comparison of $\sigma$-values calculated from $\delta \Delta G^{\Theta}$ with proposed $\sigma$-values from Table 1.8 .

| Heterocycle |  | Calculated <br> $\sigma$-value |  |
| :---: | :---: | :---: | :---: | | $\boldsymbol{\sigma}$-value from |
| :---: |
| Table 1.6 |

Table 5.3 shows that the proposed $\sigma$-values from Table 1.8 do not correlate with the calculated $\delta \Delta G^{\Theta}$ data from $\mathbf{3 m - 0}$. The successful fitting of our experimental data to calculated $\delta \Delta G^{\Theta}$ values for compounds 3a-h, and the subsequent fitting of this computational data to $\sigma$ values of known reliability, suggests that the proposed $\sigma$-values for heterocyclic compounds displayed in Table 1.8 are at the very least not applicable to the system under investigation here.

The calculated energy gap of the pyridine-containing compound $\mathbf{3 0}$ (Table 5.3) suggests that such a compound would undergo rapid $H / D$ exchange (and presumably racemisation) under the experimental conditions used in Chapter 3. This strong anion stabilisation by the 4 pyridine moiety is of particular interest. Database mining studies showed that pyridine was
the second most frequently occurring aromatic group (after benzene) adjacent to a stereogenic centre in the AstraZeneca ISAC database (Section 2.3.2). Literature studies also show that pyridine is the most commonly found heterocycle in drug molecules. ${ }^{6,7}$ The results in Table 5.3 suggest that a drug molecule with a 4-pyridine substituent adjacent to a stereogenic centre of type R''R'RC-H, could be at particular risk of configurational instability under physiological conditions, even if other substituents are not stabilising towards an anion.

### 5.2.2 Computational Analysis Without PCM

Computational analysis in the gas-phase is less expensive than analysis using a solvent model such as PCM. Although PCM is a relatively cheap solvent model, it still requires the use of far greater computing resources than gas-phase calculations. As a result, gas-phase calculations would be preferable to calculations performed using the PCM if they could be shown to produce results of comparable predictive power. We therefore carried out gas-phase calculations on $\mathbf{3 a - h}, \mathbf{3 k - 1}$ and $\mathbf{6 e}$ (Table 5.4).

Table 5.4: $\Delta G^{\theta^{*}}$ and $\delta \Delta G^{\ominus}$ for $\mathbf{3 a - h}, \mathbf{3 k}-1$ and $\mathbf{6 e}$, from calculated energies of each structure in both protonation states calculated in the gas-phase. ${ }^{\text {a }}$

| Compound | $\Delta \boldsymbol{G}^{\boldsymbol{\theta}^{\boldsymbol{*}}} / \mathrm{kJ} \mathrm{mol}^{-1}$ | $\boldsymbol{\delta} \Delta \boldsymbol{G}^{\boldsymbol{\theta a}} / \mathrm{kJ} \mathrm{mol}^{-1}$ |
| :---: | :---: | :---: |
| 3a | 1449.163 | 0.000 |
| 3b | 1456.394 | 7.231 |
| 3c | 1458.116 | 8.953 |
| 3d | 1440.226 | -8.937 |
| 3 e | 1436.366 | -12.797 |
| 3 f | 1429.802 | -19.360 |
| 3g | 1425.688 | -23.475 |
| 3h | 1406.583 | -42.580 |
| 3k | 1414.002 | -35.161 |
| 31 | 1431.078 | -18.084 |
| 6 e | 1433.420 | -15.742 |

[^21]The rate constants for general-base catalysed H/D exchange ( $k_{\mathrm{gb}}$, from Tables 3.2, 3.7 and 4.3) were plotted against $\delta \Delta G^{\ominus}$ (from Table 5.4) for compounds $\mathbf{3 a - h}, \mathbf{3 k - I}$ and $\mathbf{6 e}$ (Figure 5.6).

Figure 5.6: Correlation of $\delta \Delta G^{\theta}$ from gas-phase with $\log k_{\mathrm{gb}}$ (determined at $37^{\circ} \mathrm{C}, I=1 \mathrm{M}$ ) for ( $\left.\mathbf{\bullet}\right) \mathbf{3 a - h}, \mathbf{3 k - I}$ and ( $\left.\mathbf{\Delta}\right) 6$ e. $\mathrm{R}^{2}=0.755$ (fitted to only).

Figure 5.6 shows only a very loose correlation between the experimentally-determined rate constants for H/D exchange of $\mathbf{3 a} \mathbf{- h}, \mathbf{3 k} \mathbf{- 1}$ and $\mathbf{6 e}$ with the values of $\delta \Delta G^{\ominus}$ calculated in the gas-phase. A greater rate constant for H/D exchange broadly correlates with a smaller value of $\delta \Delta G^{\ominus}$, although the relationship is far less consistent than that shown in Figure 5.4 when the PCM was employed. This is reflected in the $R^{2}$ values determined for the data in the two graphs; $\mathrm{R}^{2}=0.968$ and 0.755 for the PCM and gas-phase calculations, respectively. These results suggest that employment of the PCM is necessary if computational chemistry is to be used to predict rate-constants of $H / D$ exchange or racemisation for stereogenic centres of type R'R'RC-H.

### 5.2.3 Geometry of Computational Structures

The lowest energy geometries of both neutral and anionic states of $\mathbf{3 a}$ when PCM is applied are displayed in Figure 5.7.
a)

b)

Figure 5.7: Lowest energy geometries found when applying the PCM for 3a, a) protonated at stereogenic centre, b) deprotonated at stereogenic centre.

The geometries of the lowest energy structures found are quite consistent for the set of compounds $\mathbf{3 a - h}$. For each compound $\mathbf{3 a - h}$, the neutral species has the configuration as seen in Figure 5.7a for 3a, with the phenyl ring perpendicular to the main chain of the molecule. Generally, the lowest energy configurations found for the anionic species of 3a-h are as depicted for $\mathbf{3 a}$ in Figure 5.7b, with the planar carbanion in the same plane as the phenyl ring and the amide group perpendicular to this. The only difference from the geometry depicted in Figure 5.7 b found for the anions of the set $\mathbf{3 a - h}$, is the orientation of the ester group. For compounds 3a-b, f-g the orientation is as shown in Figure 5.7b, with the methoxy group of the ester pointing away from the phenyl ring. For compounds $\mathbf{3 c} \mathbf{e} \mathbf{e}, \mathbf{h}$ the orientation is reversed, with the carbonyl group of the ester pointing away from the phenyl ring. This alternative configuration is illustrated in Figure 5.8, for the anionic species of $\mathbf{3 c}$.

Figure 5.8: Lowest energy geometry found when applying the PCM for anionic species of $\mathbf{3 c}$.

For the anions of compounds $\mathbf{3 c} \mathbf{c} \mathbf{e}, \mathbf{h}$ the energy of the structure with geometry as depicted in Figure 5.7 b was found to be slightly higher $\left(0.228 \mathrm{~kJ} \mathrm{~mol}^{-1}\right.$ for $\mathbf{3 c}$, number of decimal places carried through from Gaussian output) than that for the orientation with the carbonyl pointing away from the phenyl group (Figure 5.8). For the anionic species of each compound $\mathbf{3 c} \mathbf{c} \mathbf{e}, \mathbf{h}$, the lowest energy structure found when not using the PCM solvent model was with the methoxy group of the ester away from the phenyl ring. This suggests that the interactions of the phenyl ring substituents in $\mathbf{3 c - e}, \mathbf{h}$ with the continuum solvent model, somehow causes the geometry of the anionic species to differ from that displayed by 3a-b, f-g. For each compound 3a-h, the anionic structure was also investigated with the carbonyl orientated in the opposite direction to ensure the lowest energy structure was taken in each case.

To further understand the anion-stabilising effect of the different substituents, the HOMO of 3a deprotonated at the stereogenic centre was visualised (Figure 5.9).

Figure 5.9: Lowest energy geometry found for 3a deprotonated at the stereogenic centre, with HOMO displayed.

The HOMO of the deprotonated species of 3a displayed in Figure 5.9 formally corresponds to the negative charge formed by removal of the proton bound to the stereogenic centre. Figure 5.9 shows that the orbital is delocalised over the entire molecule, suggesting all substituents on the stereogenic centre play a role in anion stabilisation. This observation is consistent with the presumed additivity of substituent effects.

The geometry of the lowest energy structure found for both species of amide $6 \mathbf{e}$ is similar to those found for $\mathbf{3 a}$ (Figure 5.7). The protonated species has the main chain of the molecule perpendicular to the aromatic group. The anionic species is planar at the location of the carbanion, with the primary amide group in the plane of the aromatic group. The secondary amide is perpendicular to the plane of the rest of the molecule (Figure 5.10).

Figure 5.10: Lowest energy geometry found when applying the PCM for anionic species of $\mathbf{6 e}$.

The geometry of the lowest energy structures for the neutral species of compounds $\mathbf{3 k}$, $\mathbf{l}$ was the same as that found for $\mathbf{3 a - h}$ (Figure 5.7a). However, the deprotonated species of compounds $\mathbf{3 k}$, I displayed a slightly different configuration compared to that found for $\mathbf{3 a} \mathbf{- h}$. This is depicted for $\mathbf{3 k}$ in Figure 5.11 ( $\mathbf{3 1}$ has the same geometrical arrangement).

Figure 5.11: Lowest energy geometry found for deprotonated species of $\mathbf{3 k}$.
As Figure 5.11 shows, the lowest energy geometrical structure of the deprotonated species of $\mathbf{3 k}$ (and $\mathbf{3 1}$ ) has the amide group twisted round in front of the molecule. This orientation is displayed by the lowest energy conformation of the anionic species of both $\mathbf{3 k}-\mathbf{l}$ whether the calculation is performed in the gas-phase or with the PCM employed.

The heterocyclic compounds $\mathbf{3 m} \mathbf{m}$ were found to display similar geometries to compounds 3a-h. The neutral species in each case has the aromatic ring perpendicular to the main chain of the molecule. The anionic species has a planar geometry at the site of deprotonation, with the heterocycle and methyl ester group in the same plane. The amide group is perpendicular to this plane, as in Figure 5.7b for compound 3a. For compound 3m, the anionic species has the carbonyl group of the ester pointing away from the aromatic group. For $\mathbf{3 n - 0}$, the methyl ester group is pointing away from the aromatic group.

### 5.2.3.1 Conformational Searching

Ensuring that the lowest energy structure is discovered in each case is of importance in undertaking work such as described in this Chapter. For every species of each structure analysed here, at least 4 different starting geometries were investigated. Such a process is required to ensure the molecular geometry of lowest energy is discovered in each case. Failure
to discover the lowest energy configuration could result in large errors in $\delta \Delta G^{\theta}$, and several examples of this initially occurred whilst undertaking the work in this Chapter. One such case was when trying to calculate $\delta \Delta G^{\theta}$ for $\mathbf{3 k}$. After analysing 4 different optimised molecular geometries for the anionic species of $\mathbf{3 k}$, the conformation found to have the lowest energy was that depicted in Figure 5.12.

Figure 5.12: Initial lowest energy geometry found for the deprotonated species of $\mathbf{3 k}$.

Using this particular geometry, the plot of $\delta \Delta G^{\ominus}$ against $\log k_{g b}$ for methyl ester compounds 3a-h, $\mathbf{k} \mathbf{- l}$ is depicted in Figure 5.13.

Figure 5.13: Correlation of $\delta \Delta G^{\ominus}$ with $\log k_{\mathrm{gb}}$ (determined at $37^{\circ} \mathrm{C}, I=1$ M) for $\mathbf{3 a}-\mathbf{h}, \mathbf{k}-\mathbf{l}$, using original value of $\delta \Delta G^{\ominus}$ obtained for $\mathbf{3 k}$.

As Figure 5.13 shows, using the value of $\delta \Delta G^{\theta}$ calculated for $\mathbf{3 k}$ from the geometry displayed in Figure 5.12 gives an erroneous result. Because of the incompatibility of this value of $\delta \Delta G^{\ominus}$ with the experimental data from Chapter 3, and the different geometry displayed by the structure shown in Figure 5.12 from the geometry of the other anionic species of 3a-h, I, it seemed likely that further conformational searching would find a structure lower in energy than that displayed in Figure 5.12. Such analysis yielded the geometry displayed in Figure 5.11, which gave a value of $\delta \Delta G^{\ominus}$ much more compatible with the experimental data (Figure 5.4). However, if computational analysis were to be used as a tool to investigate configurational stability of compounds not yet synthesised or for which no experimental racemisation data is available, it would not be as apparent that further investigation was required. As a result, it is imperative that a thorough investigation of many different molecular geometries be undertaken, before any conclusions are drawn from computational data.

### 5.2.4 Extension of Computational Analysis

### 5.2.4.1 Analysis of Functional Group Dependence

Calculations were also performed on several other compounds to further examine the computational method of analysis used in this Chapter for the prediction of configurational instability. According to Testa et al. ${ }^{8}$ (Table 1.1), methyl and ethyl groups are classified as neutral in the assignment of substituents as configurationally stabilising, destabilising or neutral, for stereogenic centres of type R''R'RC-H. To investigate this assignment, calculations were performed on compounds 9-11 (Scheme 5.4).

9

10

11

Scheme 5.4: Compounds 9-11.
Each compound $\mathbf{9 - 1 1}$ is based on the same framework as 3a, but with one of the substituents replaced by a methyl group. The value of $\delta \Delta G^{\ominus}$ for each compound 9-11 with respect to 3a should therefore inform as to the ability of a methyl group to stabilise a negative charge in
comparison with the substituent replaced from 3a. The results of these calculations are summarised in Table 5.5.

Table 5.5: $\Delta G^{\theta^{*}}$ and $\delta \Delta G^{\theta}$ for 9-11, from calculated energies of each structure in both protonation states, using the PCM. ${ }^{\text {a }}$

| Compound | $\Delta G^{\theta^{\boldsymbol{*}}} / \mathrm{kJ} \mathrm{mol}^{-1}$ | $\delta \Delta G^{\theta b} / \mathrm{kJ} \mathrm{mol}^{-1}$ |
| :---: | :---: | :---: |
| 9 | 1294.642 | 24.388 |
| 10 | 1385.610 | 115.357 |
| 11 | 1312.521 | 42.268 |

${ }^{2}$ Number of decimal places carried through from Gaussian output.
${ }^{\mathrm{b}}$ Relative to compound 3a.
The values of $\delta \Delta G^{\ominus}$ displayed in Table 5.5 for compounds $9-11$ strongly support the classification in Table 1.1 of a methyl group as neutral towards configurational instability, within the guidelines set out by Testa et al. Exchange of any one of the substituents of 3a for a methyl group causes a substantial increase in $\Delta G^{\text {®* }^{*}}$, suggesting a decrease in negative charge stabilisation. This suggests all substituents present in 3a help stabilise negative charge during H/D exchange, in line with observations from Figure 5.9 where the HOMO of the anion of 3a was shown to be delocalised onto all three substituents.

If the relationship in Figure 5.4 were to be extended to compounds $9 \mathbf{9 - 1 1}$, they would be expected to have $k_{\mathrm{gb}}$ and $t_{1 / 2}$ of H/D exchange as displayed in Table 5.6.

Table 5.6: Estimated values of $k_{\mathrm{gb}}$ at $37^{\circ} \mathrm{C}, \mathrm{pH}^{* *} 7.4, I=1 \mathrm{M}$ for $9-11$ and resultant halflives of $\mathrm{H} / \mathrm{D}$ exchange at 0.3 M phosphate concentration, based on $\delta \Delta G^{\theta}$ from Figure 5.5 and relationship between $\delta \Delta G^{\Theta}$ and $\log k_{\mathrm{gb}}$ from Figure 5.4.

| Compound |  | 'Predicted' $\boldsymbol{k}_{\mathrm{gb}} / \mathbf{s}^{-\mathbf{1}} \mathbf{M}^{-1}$ |  |
| :---: | :---: | :---: | :---: |
|  |  | $(2.24 \pm 0.14) \times 10^{-7} /$ days |  |
| $\mathbf{1 0}$ |  | $(1.31 \pm 0.30) \times 10^{-15}$ |  |
| $\mathbf{1 1}$ |  | $(8.48 \pm 0.80) \times 10^{-10}$ |  |

The predicted half-lives of H/D exchange of 9-11 displayed in Table 5.6 suggest that none of the three compounds would be at risk of in vivo configurational instability. This is in line with the guidelines and substituent classifications outlined by Testa et al., as none of the compounds $9-11$ would be expected to undergo pharmacologically significant $H / D$ exchange by these designations.

The greatest value of $\delta \Delta G^{\ominus}$ is displayed by compound $\mathbf{1 0}$, for which the methyl ester substituent of 3a was replaced by a methyl group. This implies that the methyl ester group of 3a provides the greatest degree of negative charge stabilisation, in line with the classification in Table 1.1 of a methyl ester group as 'strongly configurationally destabilising' (compared to the classification of amido and aryl groups as 'configurationally destabilising'). The comparative values of $\delta \Delta G^{\ominus}$ for 9 and 11 suggest that a phenyl substituent provides more stabilisation of an adjacent negative charge than an amide (bonded through nitrogen) moiety.

### 5.2.4.2 Analysis of Experimental Data from Literature

Attempts were also made to compare computational results with experimental data from the literature. The relationship between $\delta \Delta G^{\ominus}$ and rate constants of general-base catalysed H/D exchange displayed in Figure 5.4 is based on data obtained in aqueous conditions at pH 7.4 , $37{ }^{\circ} \mathrm{C}$ using phosphate buffers. Only comparison with experimental data obtained under the same (or very similar) conditions will be meaningful. As such data is sparse, the only direct comparison that could be made is with the data collected by Reist et al. ${ }^{9}$ for the amphetamines amfepramone and cathinone (Scheme 5.5). They determined rate constants of H/D exchange for both compounds at a range of phosphate concentrations, under near identical conditions and using the same method of analysis ( ${ }^{1} \mathrm{H}$ NMR spectroscopy) employed in Chapters 3 and 4. As discussed in Section 1.5.1, the amine functional group present in both amfepramone and cathinone will be protonated at the pH under which the experiments were performed. As a result, calculations were carried out on the structures depicted in Scheme 5.5, both protonated and deprotonated at the stereogenic centre.

Amfepramone

Cathinone

Scheme 5.5: Amfepramone and cathinone, protonated at amine moiety.
The $k_{\mathrm{gb}}$ values displayed in Table 5.7 were not explicitly stated, and thus were determined from the reported kinetic data (see Experimental Section 5.4.2).

Table 5.7: Rate constants of general-base catalysed H/D exchange of amfepramone and cathinone from reference 9 , determined at $37^{\circ} \mathrm{C}, \mathrm{pD} 7.4, I=0.43 \mathrm{M}$.

| Compound |  | $\boldsymbol{k}_{\mathrm{gb}} / \mathbf{s}^{-1} \mathbf{M}^{-1}$ |
| :---: | :---: | :---: |
|  |  | $(5.09 \pm 0.27) \times 10^{-3}$ |
| Amfepramone |  | $(9.80 \pm 0.87) \times 10^{-4}$ |

The calculated values of $\delta \Delta G^{\ominus}$ for amfepramone and cathinone are given in Table 5.8.
Table 5.8: $\Delta G^{\ominus^{*}}$ and $\delta \Delta G^{\ominus}$ of amfepramone and cathinone (both protonated at the amine), from calculated energies of each structure in both protonation states (at the stereogenic centre), using the PCM. ${ }^{\text {a }}$

| Compound | $\Delta G^{\theta^{*}} / \mathrm{kJ} \mathrm{mol}^{-1}$ | $\boldsymbol{\delta} \Delta \boldsymbol{G}^{\boldsymbol{\theta b}} / \mathrm{kJ} \mathrm{mol}^{-1}$ |
| :---: | :---: | :---: |
| Amfepramone | 1226.715 | -43.539 |
| Cathinone | 1233.381 | -36.873 |

${ }^{2}$ Number of decimal places carried through from Gaussian output.
${ }^{\mathrm{b}}$ Relative to compound $\mathbf{3 a}$.
The data from Table 5.7 and Table 5.8 was plotted alongside those for compounds $\mathbf{3 a - h}, \mathbf{3 k} \mathbf{k}$ (Figure 5.14).

Figure 5.14: Correlation of $\delta \Delta G^{\ominus}$ (using PCM) with $\log k_{\mathrm{gb}}$ for ( $\quad$ ) 3a-h, k-
$\mathbf{I},(\mathbf{\Delta}) \mathbf{6 e},(\nabla)$ amfepramone, $(\bullet)$ cathinone.

Figure 5.14 shows that the data for amfepramone and cathinone does not correlate particularly well with that obtained for methyl esters 3a-h, k-l. A partial explanation for the lack of correlation of the data for amfepramone and cathinone is the positive charge on the amine. This will result in a different set of errors in the computational analysis than those present in the comparison between the methyl ester species.

Figure 5.14 reveals an important limitation of the method of analysis employed in this chapter. Major changes in molecular structure will change the set of errors to the point that any correlation will break down. However, Figure 5.14 also suggests a gradient between the data points found for amfepramone and cathinone which is similar to the gradient found for 3a-h, k-l. This suggests that the introduction of a positive charge on the amine in amfepramone and cathinone adds (or removes) a consistent error to $\Delta G^{\ominus^{*}}$, compared to the error found in $\Delta G^{\Theta^{*}}$ for $\mathbf{3 a - h}, \mathbf{k}-\mathbf{l}$. Further experimental work would be required to confirm and quantify such a standard 'offset' for calculations performed on a compound containing a protonated amine. Hypothetically, it may also prove possible to discover standard 'offsets' for other major structural changes.

### 5.3 Conclusion

Comparison of computationally determined values for $\delta \Delta G^{\ominus}$ with experimentally determined rate constants for general-base catalysed $H / D$ exchange has produced the following conclusions.

First, correlation analysis shows that for minor changes in molecular structure, computationally determined values of $\delta \Delta G^{\Theta}$ could be used to predict $k_{\mathrm{gb}}$.

Second, major changes to the molecular structure will introduce additional errors that make the relationship between computationally determined $\delta \Delta G^{\ominus}$ and $k_{\mathrm{gb}}$ break down at this level of theory.

Third, employment of the Polarisable Continuum Model leads to increased accuracy in correlation analysis.

Fourth, determination of $\delta \Delta G^{\Theta}$ for compounds $9-11$ broadly supports the assignments of functional groups ability to stabilise an anion by Testa et al. (Table 1.1).

### 5.4 Experimental

### 5.4.1 Computational Details

All computations were performed at the RB3LYP/6-31 $+\mathrm{G}(\mathrm{d}, \mathrm{p})$ level of theory, using the Gaussian03 suite of programs. ${ }^{10}$ Geometry optimisation was performed prior to frequency calculations. A range of starting geometries ( $>4$ ) was tested in each case; the lowest energy optimised geometry is reported for each compound. Energies are reported in Hartrees. All compounds were analysed with the PCM model, using the Gaussian default parameters for water. Compounds $\mathbf{3 a - h}, \mathbf{k - l}$ and $\mathbf{6 e}$ were also analysed in the gas-phase. Molecular orbitals were calculated using GAMESS. ${ }^{11}$ Visualisations were created using the MacMolPlot program. ${ }^{12}$

### 5.4.2 Determination of $\boldsymbol{k}_{\mathrm{gb}}$ for Amfepramone and Cathinone

The rate constants for general-base catalysed H/D exchange of amfepramone and cathinone (Section 5.2.4.2) were obtained from the data reported by Reist et al. ${ }^{9}$ This data is reproduced in Table 5.9.

Table 5.9: Rate constants of $\mathrm{H} / \mathrm{D}$ exchange for amfepramone and cathinone from reference 9, in $\mathrm{D}_{2} \mathrm{O}$ phosphate buffers of $\mathrm{pD} 7.4, I=0.43$, at $37^{\circ} \mathrm{C}$.

| phosphate conc. / M | [ $\mathrm{HPO}_{4}{ }^{\text {2-] }}$ ] conc. / M | $k_{\text {deut }} / \mathrm{s}^{-1}$ |  |
| :---: | :---: | :---: | :---: |
|  |  | Amfepramone | Cathinone |
| 0.00067 | 0.00041 | $1.50 \times 10^{-7}$ | - |
| 0.0013 | 0.00079 | $2.72 \times 10^{-6}$ | - |
| 0.0020 | 0.0012 | $3.33 \times 10^{-6}$ | - |
| 0.013 | 0.008 | $3.06 \times 10^{-5}$ | - |
| 0.067 | 0.041 | $1.61 \times 10^{-4}$ | $4.95 \times 10^{-5}$ |
| 0.100 | 0.061 | - | $6.50 \times 10^{-5}$ |
| 0.133 | 0.081 | $3.56 \times 10^{-4}$ | $8.11 \times 10^{-5}$ |
| 0.167 | 0.102 | - | $9.78 \times 10^{-5}$ |
| 0.200 | 0.122 | $6.47 \times 10^{-4}$ | $1.30 \times 10^{-4}$ |

From the data displayed in Table 5.9, the rate constant of $\mathrm{H} / \mathrm{D}$ exchange was plotted as a function of basic buffer component (Figure 5.15 and Figure 5.16). From these plots, $k_{\mathrm{gb}}$ and $k_{0}$ ' were obtained for amfepramone and cathinone.

Figure 5.15: Variation of $k_{\text {deut }}$ of amfepramone with $\left[\mathrm{HPO}_{4}{ }^{2-}\right]$ at $37^{\circ} \mathrm{C}, \mathrm{pD}$ $7.4, I=0.43 . k_{\mathrm{gb}}=(5.09 \pm 0.27) \times 10^{-3}, k_{0}{ }^{\prime}=(-1.34 \pm 1.54) \times 10^{-5}$.

Figure 5.16: Variation of $k_{\text {deut }}$ of cathinone with $\left[\mathrm{HPO}_{4}{ }^{2-}\right]$ at $37{ }^{\circ} \mathrm{C}, \mathrm{pD} 7.4$, $I=0.43 . k_{\mathrm{gb}}=(9.80 \pm 0.87) \times 10^{-4}, k_{0}{ }^{\prime}=(4.37 \pm 7.48) \times 10^{-6}$.

## 6 Epilogue

### 6.1 General Conclusions

This thesis describes our endeavours to improve our understanding of the many factors affecting configurational instability, specifically addressing the potential problem of enantiopure compounds undergoing racemisation after being administered as a drug.

Literature studies suggested that the threat of racemisation under aqueous conditions is greatest for compounds with a stereogenic centre of the type R' ${ }^{\prime}$ ' $R C$ - $H$. If adjacent $R$ groups can stabilise a negative charge, then an anion may be formed by deprotonation at the stereogenic centre and any enantiopurity will be lost as a result. Research by the Testa group classified specific groups as increasing or decreasing configurational stability. A wealth of literature from the Richard group into how adjacent functional groups influence the $\mathrm{p} K_{\mathrm{a}}$ of carbon acids also provided insight into how functional groups bound to a stereogenic centre will affect the lability of the proton.

The goal of this project was thus to test the conclusions from these studies as well as to expand on them, through determining rate constants for the $H / D$ exchange reactions of selected compounds. From these rate constants, it was hoped that mechanisms and substituent effects for the process could be elucidated. To do so, a range of experimental techniques and methods in physical organic chemistry were used.

The database mining studies outlined in Chapter 2 were undertaken with the intent of exploring and categorising the structure of stereogenic centres most commonly found in pharmacologically-active compounds. To this end, the wealth of compounds found in the databases under analysis (ISAC and IBEX databases, containing over 1 million and over half a million compounds respectively) comprises a great resource. Specifically, the goal of this part of our research was to assess which combinations of functional groups are frequently found together around stereogenic centres and to identify frequently found combinations thought to be at risk of racemisation for further analysis. It became apparent that when so many compounds containing stereogenic centres were under analysis, it would be possible to find almost any combination of substituents that could be imagined. As a result it was decided to narrow down the analysis to the top 250 most frequently appearing combinations in each database. In this selection, the majority of stereogenic centres were not deemed to be susceptible to in vivo racemisation. However, there were many regularly-appearing combinations that did appear to be at risk of configurational instability under the conditions
under investigation. In particular, the combination of adjacent carbonyl, nitrogen and aromatic groups on a stereogenic was commonly found. As a result, this particular combination was targeted for further investigation through physical experimentation.

In Chapter 3, specific rate constants for proton-deuterium exchange (as a model for configurational instability of stereogenic centres carrying a relatively labile proton) were determined for a series of $N$-acetyl arylglycine methyl esters. The magnitude of these rate constants showed that compounds containing stereogenic centres of this type are at risk of undergoing racemisation under physiological conditions. The linear relationship between rate constants for proton-deuterium exchange with basic buffer component showed that the process under analysis is general-base catalysed. These results also broadly fit with the assignments by Testa et al. of functional groups as promoting or retarding configurational stability when adjacent a stereogenic centre. Hammett correlations showed that electron-withdrawing groups increased rate constants of racemisation, through stabilisation of a (developing) negative charge. Comparison of the rate constants for racemisation with rate constants for proton-deuterium exchange allowed us to conclude that these two processes take place via an $\mathrm{S}_{\mathrm{E}} 1$ mechanism, consistent with the mechanism determined for similar structures. For H/D exchange of $N$-acetyl phenylglycine methyl esters the best Hammett relationship was found with $\sigma^{-}$values. Rate constants for proton-deuterium exchange were also determined for thiophene-substituted analogues, and were of a magnitude that suggests that such compounds are at risk of racemisation under physiological conditions. The rate constants for one of the thiophene-containing compounds also suggests that a 2-thiophene moiety is more electron-withdrawing than any of the substituted-phenyl groups also analysed in Chapter 3. Attempts to fit these heterocycle-containing analogues into the previously-mentioned Hammett analysis using $\sigma$ values found in the literature proved successful.

Rate constants for proton-deuterium exchange for a set of $N$-substituted phenylglycine amides were determined in Chapter 4, for the purpose of comparison with those determined for N acetyl phenylglycine methyl esters in Chapter 3. The rate constants determined in Chapter 4 suggest that the $N$-substituted phenylglycine amides investigated are not at risk of configurational instability under physiological conditions. This dataset, in combination with the data collected in Chapter 3, allowed for a direct comparison of the effects of an ester and of an amide on configurational instability, and showed that an adjacent ester group will destabilise a stereogenic centre of type R''R'RC-H more than an amide group in the same position. These findings are consistent with the assignments made by Testa et al. As with the ester compounds analysed in Chapter 3, the amides investigated in Chapter 4 undergo
proton-deuterium exchange through general-base catalysis and via an $\mathrm{S}_{\mathrm{E}} 1$ mechanism. Variable-temperature work in Chapter 4 allowed for the determination of thermodynamic activation parameters. The large positive enthalpy and negative entropy of activation found were consistent with the $\mathrm{S}_{\mathrm{E}} 1$ mechanism. The variable-temperature work also showed that high-temperature kinetics could potentially be used for rapid screening, providing approximate information on configurational instability at lower temperatures.

Chapter 5 used computational chemistry to relate experimental data with theoretical calculations. Because the proton-deuterium exchange reactions examined in Chapters 3 and 4 were found to proceed through an $\mathrm{S}_{\mathrm{E}} 1$ mechanism, it was suspected that the stability of the anion formed upon deprotonation at the stereogenic centre relative to the compound prior to deprotonation could provide a good correlation with the rate at which proton-deuterium exchange occurs. It was found that this calculated energy difference correlated well with the rate constants of proton-deuterium exchange experimentally determined in Chapters 3 and 4, when the PCM solvent model is applied. This relationship holds well for minor structural changes, such as the modification of Hammett substituents, but less well for major structural changes.

### 6.2 Outlook

It is hoped that the correlation between the computationally-calculated energy differences and the experimentally-determined rate constants could be of significant use to the pharmaceutical industry, by enabling the prediction of configurational instability in a compound only from calculations. In order for this to become reality a great deal of further work would have to be done. Foremost, the number of compounds for which rate constants of proton-deuterium exchange has been determined under conditions analogous to those used in Chapters 3 and 4 would need to be greatly expanded. Correlation with a greater number and a wider range of structures would allow for increased confidence in the relationship. An increase in the range of structures may also allow for the discovery of a standard 'offset' for functional groups which significantly change the electronic properties of the compound, such as the cation found in the quaternary amines amfepramone and cathinone analysed in Chapter 5.

[^6]:    ${ }^{\text {a }}$ from a total of $1,607,343$ stereogenic centres

[^7]:    ${ }^{2}$ from a total of 989,125 stereogenic centres

[^8]:    ${ }^{\text {a }}$ from a total of 989,125 stereogenic centres

[^9]:    * $354^{\text {th }}$ most frequently occurring combination of substituents in the IBEX database, appearing in 205 stereocentres.

[^10]:    ${ }^{+}$ACE-Angiotensin-Converting Enzyme.

[^11]:    * When reporting the acidity of $\mathrm{D}_{2} \mathrm{O}$-based solutions, the term ' $\mathrm{pH}^{*}$ ' is often used to denote the value recorded on a standard electrode. It is widely accepted that deuterium isotope effects cause the actual pD of $\mathrm{D}_{2} \mathrm{O}$ solutions to equal $\mathrm{pH}^{*}+0.4$ units. However, the value of $\mathrm{pH}^{*}$ is commonly used as a deuterium isotope effect also alters the position of equilibrium between buffer components, generally raising the $\mathrm{p} K_{\mathrm{a}}$ by $0.5-0.7$ units. This approximately offsets the error from the uncorrected pH meter reading. The term ' pH **' adds the extra caveat that the buffers used are not temperature corrected, i.e. the values displayed were determined at $25^{\circ} \mathrm{C}$ and the buffers were used at $37^{\circ} \mathrm{C}$.

[^12]:    * The experiments discussed from reference 18 were undertaken at pH 10 , where the ratio of arylglycine free base (anion) to zwitterion is approximately $100: 1$. However, the rate constant of racemisation for the zwitterion over the free base is approximately $100,000: 1$, suggesting that the zwitterion is the major species undergoing racemisation and supporting the assertion of stabilisation from $-\mathrm{NH}_{3}{ }^{+}$.

[^13]:    " Experimentally determined ratio of $k_{\text {deut }}: k_{\text {hyd }}$ for $\mathbf{3 a}$ in 0.3 M buffer, displayed in Table 3.1.

[^14]:    ${ }^{+}$The term ' $\mathrm{pH}^{*}$ ' is used in this chapter for the experiments carried out at $60,70,80$ and $90{ }^{\circ} \mathrm{C}$ as the pH of the buffers used was corrected for temperature, so that the buffers were at the desired pH at the temperature at which experiments were carried out. See experimental (Section 4.6.3.2) for further details.

[^15]:    $\ddagger$ As discussed in Section 4.4.1.2, $k_{\text {deut }}$ values determined at $90^{\circ} \mathrm{C}$ include a substantial degree of specific basecatalysis by $\mathrm{OH}^{-}$ions and/or uncatalysed reaction not observed at $37^{\circ} \mathrm{C}$. Therefore, extrapolation to predict rate constants of H/D exchange at high temperature from experimental data obtained at $37{ }^{\circ} \mathrm{C}$ will exclude any contribution from $k_{0}$ ', and hence is unlikely to be accurate.

[^16]:    ${ }^{\text {a }}$ average of two experiments

[^17]:    ${ }^{\text {a }}$ benzoyl ring substituent
    ${ }^{\mathrm{b}}$ average of two experiments

[^18]:    ${ }^{+}$Many errors present in the calculations will have previously been cancelled when subtracting the calculated energies of the two protonation states.

[^19]:    * In this Chapter, the term 'structure' shall be used to define a general molecular scaffold, such as 3a. The term 'species' shall be used to distinguish between the different protonation states of the stereogenic centre, for each structure.
