# SYNTHESIS AND COORDINATION CHEMISTRY OF COMPLEXES OF CHELATING PHOSPHINE-CARBENE LIGANDS 

## By:

SULTAN M. H. AL-SAADI

Submitted in partial fulfilment of the requirements of the Degree of

Doctor of Philosophy<br>School of Chemistry<br>Cardiff University<br>Wales, UK

This dissertation was carried out in the Department of Chemistry at the University of Wales Cardiff under the supervision of Prof. Peter G. Edwards and Dr. P. D. Newman.

## Declaration

This work has not previously been accepted in substance for any degree and is not being concurrently submitted in candidature for any degree.

Signed $\qquad$ Dated $\qquad$

## Statement 1

This thesis is being submitted in partial fulfilment of the requirements for the degree of PhD .

Signed $\qquad$ Dated $\qquad$

## Statement 2

This thesis is the result of my own investigations, except where otherwise stated. Other sources are acknowledged by footnotes giving explicit references. A bibliography is appended.

Signed $\qquad$ Dated $\qquad$

## Statement 3

I hereby give consent for my thesis, if accepted, to be available for photocopying and for inter-library loan, and for the title and summary to be made available to outside organisations.

## Acknowledgements

Indeed, my deepest appreciation is due first to my supervisor, Professor Peter Edwards, for giving me the opportunity to have a lab space to work under his excellent supervision. His great insights, perspectives, guidance and sense of humour stamped in mind a charisma I wouldn't forget ever. Without his cooperation and persistent help throughout in all academic and financial matters this dissertation would not have been possible. Sincere Thanks to him to attend Spain, Belfast, Edinburgh, Bath, oxford, and leister conferences as well as many leisure trips especially the one on the Canal. Despite his many academic and professional commitments, his focus on the highest standards showed me a great individual whom inspired and motivated me.
"Thanks" wouldn't quench the thrust in my heart to our group's "Godfather", Dr. Paul Newman, Woody. He is a very powerful but quiet dynamo. I am really amazed how he could manage everyone's matters in very distinctive way of wisdom and patience. He has been very generous with his time and energy to engage ideas in improving this and others' work. Thanks for his warmth and understanding, for his help with the tone and discipline of my writing, and his effort for improving the quality of this dissertation. He is great assets to me and others at the department of chemistry. Woody sets a wonderful example of grace and humour. Without any doubt, his support made this work. I owe you a special debt.

I am very grateful for Dr. Abdul-Razzaq. He has been a wonderful source of advice, enthusiasm and encouragement at crucial decision-points along all these years. He played a significant role in helping me to achieve the first ligand precursor.
Thanks extended to Dr. Angelo Amoroso, Dr. Nancy Dervisi, and Dr. Ian Fallis for his early stage guidance.

Thanks to the crystallography team: Dr. Kariuki for being patient, Dr. Liling, Dr. Stasch, James and Baz whom all showed great effort and kindness to find a valuable single crystal. And, Thanks to Fawaz for being very helpful with its software as well.

To my dearest colleagues: Eli for her comments and supportive advices, Wenjian, Becky, Kate, Huw, Craig, Toz, Matt, Lenali, and finally my dude Chris for sharing conversations and debates in various topics and for being a good language exchange partner. I wish you a happy future.

Thanks are due to students Rhian and Huw who firstly started with this project strategy and which I have followed. They were very helpful.

I also gratefully thank Dr. Rob Jenkins for technical assistance in NMR spectroscopy and your good willing to help with a smile. My appreciation goes to the rest of the technical team at the department: Robin, JoBo, Gaz, Sham, Jamie, Alun, Dave and finally the nitrogen guy, Mal.

I want to thank the good friends that I have made in Cardiff: Khalid, Saeed, Zakarya, Abdullah, Sultan, and Salem in their support and entertainment throughout my time over there.

Thanks to Qaboos University for this scholarship and special thanks to Prof. M. Khan at the chemistry department who introduced me to Cardiff University and for his support and assistance with proof reading and comments of the draft thesis. I extend my thanks to Prof. Salma Al-Kindy, Dr. Muna Al-Mandhary, Dr. Usama, Dr. Haidar, and Prof. Majek Fatope. Thanks to the smiley face Dr. Serajul Haque Faizi for his last stage help at X-ray and NMR softwares.

Finally, my extreme gratitude goes to my parents whom their supplication never stopped even through the pain of my father's long illness. Thanks to my cousin Zakariya and my brother Nasser along with my sisters to stand on my behalf in such a crucial situation helping our father, so I had time to complete the writing of one of the greatest challenges I have ever had to face. To my wife who supported, encouraged and believed in me in all my endeavours, I do owe you special thanks. We have had fantastic beautiful memories especially with our kids as well in a very beautiful place, Cardiff, which was our honeymoon city.

#### Abstract

Results presented and discussed in this thesis are collected into 4 chapters. Chapter 1 is an introduction to the synthesis and properties of phosphine and N -heterocyclic carbene compounds and complexes. Related complexes of $N$-heterocyclic carbene-phosphine ligands are also reviewed in this chapter. The synthesis and characterisation of a new phosphinefunctionalized $N$-heterocyclic carbene ligand precursor, $\mathbf{2 . 5}$, is described in chapter 2. A synthetic route has been successfully established for this ligand which is designed with $N$ methyl group on one side of the imidazole core and a pendant $\mathrm{PR}_{2}$ moiety on the other side, (where $\mathrm{R}=\mathrm{Pr}^{i}$ ). The ring between the phosphorus group and the imidazolium ring is bound directly to give the rigidity to the whole chelating ligand structure. The corresponding phosphine-NHC ligand was generated in situ and reacted with suitable metal precursors. In addition, the reactivity of the ligand under various conditions was shown to cause cleavage of THF with concomitant formation of an alcohol group attached to the carbene's carbon atom, 2.7. Chapter 3 describes reactions with metal precursors in the presence of a base (via free carbene) or via silver transfer agents and afforded a number of new metal complexes of the phosphine-NHC ligand. These included complexes of groups 11, 10, 9 and 7: Au (3.1), Ag (3.2), Cu (3.3), Ni (3.4), Pd (3.5), Pt (3.6), Mn (3.7) and Ir (3.8). The synthesis of $\mathrm{Ag}(\mathrm{I})$ complex was achieved by the reaction of the ligand, phosphine-imidazolium salt (2.5) with $\mathrm{Ag}_{2} \mathrm{O}$. The synthesized phosphine $N$-heterocyclic carbene complexes were characterised by analytical and spectroscopic methods and in some cases by X-ray crystallography. Chapter 4 lists other attempted complexations which did not succeed to yield desired products.

# Chapter 1 

Introduction

### 1.1 Introduction:

$N$-Heterocyclic carbenes represent a growing class of ligands in transition-metal catalysis, which have several features such as stability to air and moisture, low toxicity, strong $\sigma$-donor and poor $\pi$-acceptor properties. ${ }^{1-3}$ NHC complexes find potential use for their biological activities ${ }^{4,5}$ and for their applications which include extensive studies in homogeneous catalysis. ${ }^{6-8}$

As part of a longer study into the chemistry of mixed-donor type of ligands, we sought to synthesise carbene-phosphine ligands and their complexes and to explore some aspects of their coordination chemistry. Complexes of chelating carbine-phosphine ligands are well known. ${ }^{9-11}$

The main interest of these $N$-heterocyclic carbene complexes, in comparison to phosphine complexes, resides in producing robust catalysts which will not undergo decomposition or deactivation. On the other hand, the incorporation of a weaker coordinating unit on the same ligand should ensure a good activity for catalytic applications. ${ }^{12}$

Phosphine and carbene ligands have played important roles as reactive intermediates in organometallic reactions. Since NHCs are much more stable at high temperature and pressure and can form stronger bonds to metals than phosphines, the tendency toward such type of complexes is on the rise. Basicity of NHC is even more than the most basic phosphine, and thus it influences the reactivity of the applied catalytic system. Synthesis and characterization of bidentate carbene-phosphine ligands in order to promote homogenous catalytic reactions are of paramount importance.

### 1.2 General properties of phosphines

Phosphine ligands have been used efficiently in homogeneous catalysis for long time. Tertiary phosphines $\left(\mathrm{PR}_{3}\right)$ readily coordinate to a large number of transition metals. Their ability to act as both $\sigma$-bases as well as $\pi$-acids enhances the stabilisation of metals in low oxidation states. A phosphine-metal bond is characterised as $(\mathrm{P} \rightarrow \mathrm{M}) \sigma$ donation of the phosphorus lone pair electrons to an empty p or d s-orbital of the metal, and the $\pi$-bond $(\mathrm{M} \rightarrow \mathrm{P})$ is derived from back-donation to the empty orbital on the phosphine from the filled metal d-orbital, Figure $1 .{ }^{13-16}$ The strength of the $\sigma$-bond depends mainly on the Lewis acidity of the metal; the more electropositive metals form stronger $\sigma$-bonds. A phosphine will

Figure 1: Phosphine donation and metal back donation
increase its $\pi$-acidity, and will thus be able to accept more $\pi$-donation from the metal's dorbitals. Phosphines with more $\pi$-acceptor character will decrease (by competition) the amount of back donation that is possible to the other ligands bonded to the same metal. ${ }^{17}$ The nature of the " R " substituents on the phosphorus atoms may influence the degree of donor or acceptor ability of this phosphine ligand. In general, alkyl phosphines are less $\pi$-acidic than aryl phosphines due to the relatively lower withdrawing (greater electron donating) behaviour of alkyl substituents. ${ }^{18-20}$

### 1.3 General properties of $\boldsymbol{N}$-heterocyclic carbenes (NHCs)

Two types of carbenes, singlet (Fischer type ${ }^{21}$ ) and triplet (Schrock type ${ }^{22}$ ), Figure 2, are observed. These are distinguished by the two possible arrangements (spin states) of the electrons available for donation to a metal ion when the carbene acts as a ligand. The triplet variant is the most stable type due to the preferred low energy configuration with one electron in each of the carbon $\sigma$ - and $p-\pi$ orbitals; the alternative singlet state has both electrons in the $\mathrm{sp}^{2}$ orbital and requires spin pairing which causes this state to be slightly higher in energy. ${ }^{23}$

singlet

triplet

Figure 2: Schrock and Fischer types of carbene.

Fig. 3A: Contribution between NHC and metal

NHCs have a singlet configuration with two electrons in the carbon $\sigma$ - orbital and coordinate to the metal by a predominantly $\sigma$-bond with little or no back-bonding, Figure $3 \mathrm{~A} .{ }^{24}$ However, changing the substituents to $\sigma$-electron donating ones may favour the triplet state due to the small $\sigma$ - $\mathrm{p} \pi$ gap.

Donation (mesomeric effect) from the filled nitrogen $\mathrm{p} \pi$-orbitals into the empty $\mathrm{sp}^{2}$ of the carbene carbon is mainly responsible for the stability of the NHC system. ${ }^{25,26}$ The $\sigma$ electron density on the carbon centre is also pulled towards the more electronegative nitrogen atoms (inductive effect) which helps to stabilise the carbene lone pair, Figure 3B. ${ }^{27}$ Carbenes flanked by substituent on the imidazolium ring will provide a steric protection which certainly

Figure 3B: Stabilisation of free carbene through mesomeric (M) and inductive effects (I).
enhances its stability. ${ }^{28}$ Donating substituents on the carbene would add an electronic stabilising factor that may also reduce its susceptibility to nucleophilic attack. ${ }^{29}$ Therefore, the mesomeric-push from the neighbouring nitrogen atoms, the inductive-pull by these nitrogen atoms, and the electronic-push of the substituents are dominant factors that influence the stability of NHCs.

The coordination chemistry of neutral NHCs is dominated by the ligands acting as 2electron donors in a manner similar to tertiary phosphines, ${ }^{11,30-33}$ NHCs are, in general, even stronger $\sigma$-donors than phosphines. ${ }^{34,35}$ They are very weak $\pi$-acceptors but strong $\sigma$-bases which likely have a large trans influence. Thus NHCs bind to transition metals by $\sigma$-donation with minimal $\pi$-accepting ability. ${ }^{27,36,37}$ Even for electron-rich transition metals, the contribution from back-bonding is very small. ${ }^{31-33,38}$ As mentioned earlier, this is because the $\mathrm{p} \pi$-orbital of the carbene carbon is occupied by the donation of electron density by the neighbouring nitrogen atoms. ${ }^{27}$ X-ray diffraction data has also shown that M-NHC bond lengths are typically similar to those of M-C single bonds. ${ }^{34,38,39}$ The most acidic proton in imidazolium salts is that at the $\mathrm{C}_{2}$ carbon atom, therefore $\mathrm{C}_{1}$-coordinated metal imidazol-2ylidenes are referred to as normal carbenes, Figure 4. However, abnormal carbenes refers to when the coordination goes to the other carbons on the imidazolium ring, $\mathrm{C}_{3}$ or $\mathrm{C}_{4}$. One of the more useful physical properties is the diagnostic chemical shift of the carbenic carbon atom in the ${ }^{13} \mathrm{C}$-NMR spectrum, which, normally, is in the range between 200 and 300 ppm . Upon coordination to metal centres, the ${ }^{13} \mathrm{C}$ carbene resonance usually shifts upfield. These properties have several advantages for selected metals in specific oxidation states such as: high thermal stability, resistance to ligand dissociation, robust binding to the metal. ${ }^{30,31,40,41}$ In addition, these ligands are not readily susceptible to any nucleophilic or electrophilic attack, and tend not to participate in rearrangements within the metal coordination sphere. ${ }^{10,40,42}$

Figure 4: Numbering of a rigid chelating phosphine-carbene ligand

The nature of the carbene moiety assists the initiation and propagation of the catalytic reaction. ${ }^{32} \mathrm{We}$ are interested in coordinating the $\mathrm{C}_{2}$ carbon and phosphine to transition metals and exploiting the features of these bidentate carbene-phosphine complexes, i.e. stability of the carbene-metal bond and the activity (easy dissociation) of the phosphine. ${ }^{11,43}$ In contrast to metal phosphine complexes, they form metal complexes that have higher stability toward heat, moisture, and oxygen. ${ }^{44}$

### 1.4 Preparation of free $N$-heterocyclic carbenes (NHCs)

The most frequently used method for the generation of a free carbene is based on the deprotonation of an imidazolium salt at the 2-position by a strong base. These reactions require Schlenk-line techniques due to their air/moisture sensitivity. Obviously this type of reaction must be performed under a dry, inert atmosphere in non-protic solvents or compounds of even moderate acidity. Arduengo's group used bases such as $\mathrm{KOBu}^{\mathrm{t}}$ and NaH at room temperature. ${ }^{29}$ Some functionalised groups on imidazolium salts cannot be reacted with such strong bases. Lithium alkyls, e.g. BuLi, ${ }^{33,45}$ are also effective reagents in the deprotonation of imidazolium salts, while milder reagents such as amides, ${ }^{9,42,43,43,46,47}$ e.g. $\mathrm{K}\left[\mathrm{N}\left(\mathrm{SiMe}_{3}\right)_{2}\right]$ and $\mathrm{Li}\left(\mathrm{N}^{i} \mathrm{Pr}_{2}\right)$, have proven to be reliable. The nature and amount of base and

Scheme 1: Formation of imidazoline-2-ylidene
solvents are very important to optimise the reaction rates and overall yields. A range of imidazolium salts are available by consecutive alkylation of imidazole which in turn will react with organometallic or inorganic bases in nonprotic solvents (deprotonation step) to form the corresponding free carbenes (imidazole-2-ylidenes), Scheme 1.40,42

Carbenes are highly air and moisture sensitive and can also be a problem with stability if the NHC functional groups have acidic protons. A method to avoid such problems involves forming the free NHC at low temperature with bases such as $\mathrm{KN}\left(\mathrm{SiMe}_{3}\right)_{2}$, followed by in situ reaction with the metal precursor. ${ }^{45,48,49}$ The deprotonation of imidazolium salts by the base $\mathrm{KN}\left(\mathrm{SiMe}_{3}\right)_{2}$ has proven to be highly effective. This is due to the fact that the deprotonation of a range of imidazolium salts by this base is very efficient with imidazolium salts that contain acidic protons when used at low temperature. ${ }^{47,48} \mathrm{HN}\left(\mathrm{SiMe}_{3}\right)_{2}$ and KX as by-products of the reaction between the imidazolium salt and the base $\mathrm{KN}\left(\mathrm{SiMe}_{3}\right)_{2}$ are easily removed.

### 1.5 Coordination chemistry of bidentate (carbene-phosphine) system

Monodentate NHCs have been found to stabilise catalytic cycles and have advantages over the monodentate phosphorus ligand systems. Bidentate phosphine ligands have played a major role in homogeneous catalysis for a number of years. Later on, chemistry of bidentate carbene systems came into focus. However, this thesis will concentrate on carbene-phosphine bidentate ligands and their complexes.

The $\sigma$-donating phosphine group tethered to the NHCs would add some importance to the ligand design and its catalyst cycle. Firstly, the phosphine is expected to bind strongly to the transition metals. Secondly, the rigidity of the ring would fix the size of the chelating ring and highly promote ligand lability at the position trans. Thirdly, since carbene and phosphine are known as strong trans effect/influence ligands, so they would be able to activate/labilise groups coordinated in a position trans to them. Since tertiary phosphines $\left(\mathrm{PR}_{3}\right)$ and nucleophilic heterocyclic carbenes (NHC) each have many advantageous properties such as a large trans effect or influence respectively (but different donor/coordination properties), ${ }^{43}$ combined functionalities should be effective in promoting migratory reactions of substrate molecules coordinated in trans positions, which make them desirable as novel ligands. There is also an interest in the bonding properties of ligands that must bind mutually cis sites since these would require remaining reactive sites to be mutually cis to each other (ideal for migration reactions) as well as simultaneously trans to the carbene's trans-influence or the phosphine's trans-effect.

A rigid bidentate carbene-phosphine coordination sphere is formed by covalently binding an imidazolium ring to a phenyl ring. With this aim, we have prepared a ligand with rigid $o$-phenylene backbone spacers and alkyl phosphine donors, Figure 5. For ligands based upon this class, chelate complexes may be expected where the ligand binds through the imidazole's carbene carbon ( $N$-heterocyclic carbene) and phosphine donor. This, in turn, will force the coordination sphere metal-carbene to be co-planar. Chelating carbene-phosphine ligands bearing various aliphatic and aromatic substituents would be expected to have interesting properties of the resulting metal complexes. The rigid backbone may be expected to enhance the stability of complexes to a greater extent than the currently known related systems with aliphatic backbone. As well, bulkiness of functionalized groups and their steric effect may enhance the stability and reactivity. Complexes of this type of ligands might catalyse a range of organic reactions. They are expected to enhance reactivity. Whereas previous literatures were dominated by aryl phosphine, a further modification involves the substituent at the phosphorus moiety. So, we are interested in coordinating the $C_{2}$-carbon and phosphine to some transition metals and exploiting the features of these bidentate carbenephosphine complexes, i.e. the stability of the carbene-metal bond and the potential dissociation, of the phosphine. ${ }^{11,43}$

Figure 5: Proposed rigid bidentate functionalized carbene-phosphine

### 1.6 Coordination chemistry of phosphine-NHC complexes

This thesis describes synthetic procedures and characterization details of a ligand of NHC with alkyl phosphine derivatives and its complexes. Complexes of $\mathrm{Cu}, \mathrm{Ag}, \mathrm{Au}, \mathrm{Ni}, \mathrm{Pd}$, Pt, Mn and Ir transition metals have been investigated and details of these will be presented. There is an abundance of such complexes in the literature. Since Wang and Lin proved the capability of $\mathrm{Ag}(\mathrm{I})-\mathrm{NHC}$ complexes as carbene transfer agents, a large number of solid state
structures of $\mathrm{Ag}(\mathrm{I})$ compounds have been published due to its easy preparation. ${ }^{50}$ Many potential applications were found for $\mathrm{Au}(\mathrm{I})-\mathrm{NHC}$ ranging from homogeneous catalysts to their pharmaceutical use as anticancer, antiarthritic, and antibacterial agents. ${ }^{51,52} \mathrm{Au}(\mathrm{I})-\mathrm{NHC}$ complexes have been used as catalysts in many important reactions, for examples, nucleophilic additions, $\mathrm{C}-\mathrm{H}$ activations, hydrogenations, and oxidations. ${ }^{50,53}$ The +II oxidation state is by far the most common for all three group 10 metals. The electronic configuration of these $\left(\mathrm{Pt}(\mathrm{II}), \mathrm{Pd}(\mathrm{II})\right.$, and $\mathrm{Ni}(\mathrm{II})$ ) complexes is $\mathrm{d}^{8}$ and so the complexes are typically square planar.

Late transition metal imidazoline-2-ylidene complexes derived from imidazole (and its derivatives) have attracted bioinorganic chemist's recent attention ${ }^{10,30,40}$ due to their role in metal-based enzymes and proteins. ${ }^{43}$ In contrast to metal phosphine complexes, metal N heterocyclic carbene complexes have high stability towards moisture and oxygen. ${ }^{36}$ In addition, the carbene ligands are hard to dissociate from the metal center. Moreover, metal N heterocyclic carbene complexes possess high thermal stability in the solid state and in solution. Finally, syntheses of the carbene ligands are more convenient and inexpensive. ${ }^{54}$

In 1991 in a landmark discovery by Arduengo et al., a thermally stable $N$-heterocyclic carbenes (NHCs) were isolated in the free state and crystallographically characterised by deprotonation of the corresponding imidazolium salt with a base, KH. ${ }^{29,38,41,42}$ The crystalline free carbene was stable in the absence of oxygen and moisture. They attributed the stability of the carbene to both steric and electronic factors. The steric factors resulted from the presence of the two adamantyl groups, which shield the carbene center and thereby enhance kinetic stability. The electronic stability of the carbene was ascribed to the electron donation of the nitrogen filled $p$-orbitals into the vacant out-of-plane $p$-orbital of the carbene combined with the sigma-electronegativity effect of the nitrogen atoms. ${ }^{12}$ However, in 1968, Wanzlick ${ }^{55}$ and Öfele ${ }^{56}$ reported independently the first stable NHC coordinated to a metal even though the carbenes were not isolated. In 1993, Lappert et al. synthesized the first (carbene-phosphine)Mo complex. ${ }^{40 \mathrm{~b}}$

A number of groups have investigated (NHC/P)-M complexes. Some have introduced various functional groups at the imidazole ring and tested the differences with one NHC and one Phosphine, bis-NHC, and bis-phosphine. In general, the more bulky the functional group the more stable the compound. As well, once the complex has NHC moiety, the better the complex catalytic operation. ${ }^{11,31,43}$ Enhanced thermal stability is found with bulky carbene ligands. ${ }^{57,58}$ However, bulkiness is not always favourable as Nolan reported for the compound $\mathrm{Cp} * \mathrm{Ru}(\mathrm{L}) \mathrm{Cl}$ where in some cases, alkyl is more favourable than aryl. ${ }^{32}$ He suggested that the
steric congestion around the carbene carbon inhibits the approach of the lone pair to overlap with the metal. Improved catalytic activity is observed in Suzuki-type coupling reactions, amination of aryl chlorides, olefin metathesis, and hydrogenation when a bulky electrondonating phosphine with an electron rich nucleophilic carbene coordinated to a metal centre.

Another essential way to form NHC complexes is by transmetallation with Ag reagents without the use of Schlenk techniques. $\mathrm{Ag}(\mathrm{NHC})$ complexes work as intermediates in the preparation of other transition metal-(NHC) complexes. In 1993, Arduengo first reported the straight forward preparation of $\mathrm{Ag}(\mathrm{NHC})$ complexes. ${ }^{59 \mathrm{a}}$ In 1998, Wang and Lin reported a major breakthrough in handling Ag as a transfer agent when 1,2diethylbenzimidazium bromide reacts with $\mathrm{Ag}_{2} \mathrm{O}$ in DCM to give the corresponding $\left[\mathrm{Ag}(\mathrm{NHC})_{2}\right]^{+}$complexes in good yield. ${ }^{59 \mathrm{~b}} \mathrm{Ag}_{2} \mathrm{O}$ became a very useful reagent in the transfer from $\mathrm{Ag}(\mathrm{I})$ to a number of transition metals.

### 1.7 N-Heterocyclic Carbene Ligands in Catalysis

Due to their $\sigma$-donor ability and strong metal-carbon bond, NHC ligands have been 60
applied as directing ligands in various catalytic transformations. Since Arduengo's discovery of stable $N$-heterocyclic carbenes, extensive research efforts have focused on the design and application of carbenes as ligands in catalysis. In 1994, Herrmann developed the use of NHCs as spectator ligands in homogeneous catalysis. He reported Heck reaction yielding the coupling product in high yield with palladium N -heterocyclic carbene complexes. Thereafter, nucleophilic $N$-heterocyclic complexes attracted growing interest in other areas of catalysis. Significant advances in catalytic performances have been achieved with nucleophilic carbene ligands in various catalytic reactions such as:
1.7.1 Ruthenium metathesis: The first well-defined ruthenium catalyst for olefin metathesis was discovered in $1992^{62 a}$, Figure 6(A). This initial ruthenium catalyst was followed in 1995 by what is now known as the first generation Grubbs catalyst ${ }^{62 \mathrm{~b}, \mathrm{c}}$, Figure 6(B), which is important as a precursor to all other Grubbs-type catalysts. A breakthrough in catalytic metathesis reactions was achieved when NHC ligands were used to replace one of the phosphines of complex 6(B). Herrmann et al. showed that having NHC moiety favours the dissociative substitution of the phosphine ligand with an olefinic substrate, showing excellent 61a,b
activities in the ring opening metathesis. The first generation Grubbs catalyst was replaced by the second generation in the same year, 1999. ${ }^{63 a}$ One of the great successes in the area of catalyst came from the modification of Grubbs ${ }^{63 \mathrm{~b}}$ first generation catalyst, with more basic

NHC, Grubbs second generation catalyst as a new generation of ring closing metathesis catalysts, Figure 6(C). The very high trans effect $N$-heterocyclic carbene (NHC) labiles the $\mathrm{P}(\mathrm{Cy})_{3}$ ligand, and the rates go up by a factor of $10^{2}$ to $10^{3}$ relative to the prior bis-PCy3 complex. This second Grubbs type of catalyst is based on a saturated $N$-heterocyclic carbene (1,3-bis(2,4,6-trimethylphenyl) dihydroimidazole). It is in common use and doesn't require a co-catalyst because the carbene is already present and its activity is very high. This catalyst is stable toward moisture and air, ${ }^{63 \mathrm{c}}$ thus is easier to handle in the lab. Replacing the phosphine ligand with more labile pyridine ligands will produce the $3^{\text {rd }}$ generation Grubb's catalyst (Fast-Initiating Catalysts), Figure 6(D). By using 3-bromopyridine, the initiation rate is increased more than a million fold. ${ }^{64}$ All Grubbs' catalysts have almost the same uses in organic synthesis, but generally with higher activity. These catalytic synthesis applications include: First metathesis, ring-opening metathesis polymerization (ROMP) of strained cyclic olefins, olefin cross metathesis (CM), ring closing metathesis (RCM) of terminal olefins under a variety of reactions conditions, and ethenolysis of internal olefins. Both the 1st and 2nd generation Grubbs' catalysts are commercially available, along with many derivatives of

Figure 6: $1^{\text {st }}, 2^{\text {nd }}$ and $3^{\text {rd }}$ generation Grubb's catalysts
the 2 nd generation catalyst. Shortly before the discovery of the Grubbs 2nd generation catalyst, a similar catalyst based on an unsaturated $N$-heterocyclic carbene (1,3-bis(2,4,6trimethylphenyl)imidazole), Figure $6(\mathrm{E})$, was reported independently by Nolan ${ }^{65 \text { a }}$ and Grubbs ${ }^{65 \mathrm{~b}}$ in March 1999, and by Fürstner ${ }^{65 \mathrm{c}}$ in June of the same year.

In the same year, 1999, the 1st generation Hoveyda-Grubbs catalyst, Figure 7(A) was reported by the Hoveyda group, ${ }^{66 a}$ and a year later, the $2 n d$ generation Hoveyda-Grubbs catalyst, Figure 7(B) was described in nearly simultaneous publications by the Blechert ${ }^{66 \mathrm{~b}}$ and Hoveyda. ${ }^{66}$ The chelating oxygen atom replaces a phosphine ligand, which in the case of the 2nd generation catalyst, gives a completely phosphine-free structure. The Hoveyda-Grubbs catalysts are more expensive and slower to initiate than the Grubbs catalyst, but they are popular because of their improved stability. ${ }^{67}$

Figure 7: 1st and $2^{\text {nd }}$ generation Hoveyda-Grubbs catalysts
1.7.2: Carbon-carbon bond formation: C - C bond forming reactions through cross-coupling plays an important role in synthetic organic chemistry. Huge interest has been focused on transition-metal catalyzed reactions of organometallic complexes. These reagents supply a source of nucleophilic carbon site which may react with an electrophilic carbon to form a new carbon-carbon bond. These type of coupling reactions are greatly involved in the synthesis of pharmaceuticals, fine chemicals, petrochemicals, agricultural chemicals, and polymers. ${ }^{20,68,69}$
1.7.3: Asymmetric catalysis: Work of Enders ${ }^{70}$ and Herrmann, ${ }^{34}$ in 1997, was the first example of chiral carbenes used in asymmetric catalysis. Enders applied the NHC and their derivatives in carbene catalysed asymmetric nucleophilic acylation processes. Since then, the field has expanded on the use of NHCs in asymmetric homogeneous catalysis. Applications include: Rh-hydrosilylation of ketones, ${ }^{34,71,72}$ olefin metathesis, ${ }^{56}$ Pd-oxindole reaction, ${ }^{61 \mathrm{~b}, 73}$

Pd-allylic alkylation, ${ }^{74} \mathrm{Rh}(\mathrm{I})$ - and $\operatorname{Ir}(\mathrm{I})$-transfer hydrogenation of ketones ${ }^{75} \mathrm{Cu}$-catalysed $76,77 \quad 78$ addition of diethylzinc to cyclohexenones, ${ }^{76,77}$ Ni-hydroamination of acrylonitrile derivatives and hydrogenation.
1.7.4: Hydrogenation: In 2001, Nolan and Burgess published two papers on iridiumcatalysed hydrogenation with NHC ligands. Nolan initiated investigations into the field using achiral monodentate NHC iridium complex for the hydrogenation of cyclohexene and 1methylcyclohexene. ${ }^{79}$ They noticed that this Ir-catalyst and Crabtree's catalyst had comparable activity at room temperature, but are more robust and efficient at higher temperature. In 2002, Buriak showed that combining NHC with phosphine ligands led to efficient systems for the hydrogenation of simple olefins. ${ }^{31}$ The comparison of Buriak's complex with its analogue where pyridine ring replaces phosphine group, for the hydrogenation of 1-methylcyclohexene and 2,3-dimethyl-2-butene, proved its superiority of catalysis in terms of activity (time and conversion percentage).

### 1.8 Coordination chemistry of phosphine-NHC complexes of Group 11, 10, Ir and Mn

Herrmann et al., ${ }^{80 a}$ in 1997, prepared a square planar mixed carbene-phosphine complex of palladium, Figure 8. The phosphine group was found to be in a cis configuration to the carbene carbon. The $\mathrm{P}-\mathrm{Pd}$ bond is, as expected, longer than $\mathrm{C}-\mathrm{Pd}$, and the $\mathrm{Pd}-\mathrm{X}$ bond trans to the carbene is longer than that trans to the phosphine showing a greater trans influence for the NHC. It shows the donation difference between the two donors.

In 1999, a method of carbene transfer between metal ions was used by Liu et al. ${ }^{80 \mathrm{~b}}$ in order to prepare other carbene species similar to Figure 8. This Pt complex of phosphinesubstituted carbene was obtained from the corresponding CO-substituted carbene.

A similar complexation in 2009 and 2010, Lee et al. ${ }^{80 c, d}$ prepared electron-rich palladium(II) complexes of mixed-donor cis-phosphine/carbene ligands which proved to be efficient as catalytic precursors in Suzuki Coupling. They found $\mathrm{PCy}_{3} /$ carbene complexes are more active than $\mathrm{PPh}_{3} /$ carbene complexes which may be attributed to the faster dissociation of labile $\mathrm{PCy}_{3}$. In 2010, Liu and co-workers showed analogus complex of a bidentate Pd$\mathrm{NHC} / \mathrm{PPh}_{3}{ }^{80 \mathrm{e}}$

Figure 8: Pd-complexation of mixed carbene-phosphine, $\left(\mathrm{PR}_{3}=\mathrm{PPh}_{3}, \mathrm{PCy}_{3}\right)$

In 1998, Leung synthesised the first stable bidentate chelating palladium carbenephosphine complex via a metal template synthesis. ${ }^{44}$ He proved that certain transition-metal phosphine complexes can serve as templates for the synthesis of chelating NHC ligands. Having a functional group within the template, such as phosphine moiety, is necessary to form chelating NHC, Figure 9.

Figure 9: Bidentate chelating palladium carbene-phosphine complex, Leung ${ }^{44}$

Cationic $\mathrm{Ni}($ II $)$ complexes of the chelating $N$-heterocyclic carbenes have been prepared and structurally characterized by Green/Danopoulos and co workers in 1999. ${ }^{81}$ This chelating di- $N$-heterocyclic carbene is the first example of methylene and ethylene-bridged dicarbene transition metal complex in this monocationic class of salts with a phosphorus group attached trans to one of the imidazolium ring, Figure 10.

A variety of mixed trans-NHC/phosphine complexes of palladium were prepared by the Herrmann group, 1999, in a similar result to his 1997's cis-NHC/P complex. ${ }^{11}$ From bisphosphine metal complexes, the replacement of one of the phosphine ligands by an NHC ligand will enhance the electron density at the metal. ${ }^{57}$

Figure 10: $\mathrm{Ni}($ II $)$ complexes of the chelating $N$-heterocyclic carbenes, Danopoulos ${ }^{81}$

This type of complexes, $\left[(\mathrm{NHC}) \operatorname{Pd}\left(\mathrm{PR}_{3}\right) \mathrm{I}_{2}\right]$, with bulky $N$-heterocyclic carbenes (NHC), Figure 11, were found to be efficient catalysts for aryl coupling reactions such as the Suzuki and Stille cross-coupling reaction. It has a combination of the advantageous stability of carbene and the good activity of the phosphine. In general, one of the interesting characteristics of the palladium(II) complexes of $N$-heterocyclic carbenes is the extraordinary thermal stability and the high dissociation energies of the Pd-NHC bond. ${ }^{37}$

Figure 11: Mixed trans-NHC/phosphine complexes of palladium, Herrmann ${ }^{11}$

In 2001, Nolan et al. prepared and examined the first mixed donor chelating phosphine-imidazolium ligand in which the phosphine was attached to the imidazolium ring by an aliphatic linker, Figure 12. This chelating bidentate phosphine-carbene ligand derived from the imidazolium salt would potentially form a more stable palladium catalyst which proved to work as a highly efficient catalytic system for Heck chemistry. A theoretical calculation study, in 1998, showed that a chelating ligand consisting of a carbene and a phosphine moiety had efficiency for the Pd-catalyzed Heck reaction. ${ }^{62}$ However, the aliphatic

Figure 12: Phosphine-imidazolium salt of Nolan et al. ${ }^{33}$
bridge may not provide a strong chelate of phosphine to metals and the ligand may be susceptible to reductive elimination due to its flexible geometry. ${ }^{33}$ Thus, replacing the ethane bridge with a more planar rigid linker, as in our system, could help to form a 'stronger' bidentate chelating system.

In 2001, a number of new cationic mixed bis-phosphine-cis-methyl/NHC Pd(II) complexes, $\left[\mathrm{Pd}\{\right.$ cis-Me- $\left.(\mathrm{NHC})\}-\mathrm{P}_{2}\right] \mathrm{BF}_{4}$, have been prepared and fully characterized and their reaction behaviour has been studied by Yates et al. ${ }^{83}$ Another paper in the same year by Cavell et al. ${ }^{84 \mathrm{a}, \mathrm{b}}$ confirmed, for the first time, that oxidative addition of different imidazolium cations to zerovalent group 10 metal precursors, Pd and Pt , can occur in order to afford mixed bisphosphine/NHC complexes, Figure 13. Fürstner, in 2003, has also shown the same result that oxidative addition of imidazolium chlorides is a method for the preparation of mixed cis-mono-phosphine/NHC complexes of $\mathrm{Pd} .{ }^{85}$

\(\mathrm{M}=\mathrm{Pd}, \mathrm{Pt}\)
```

Figure13: Mixed bis-phosphine/NHC $\operatorname{Pd}($ II $)$ complexes, Yates ${ }^{83}$

Analogous to Herrmann complexes reported in 1997, Welton and co-workers, ${ }^{86}$ in 2001, have demonstrated the in situ formation of mixed trans-di-phosphine/NHC palladium complexes which can be formed from the reaction of ionic liquids with $\operatorname{Pd}(I I)$ precursors under conditions similar to many ionic liquid mediated palladium-catalyzed coupling reactions, Figure 14.

Figure 14, ( $\mathrm{X}=\mathrm{Cl}, \mathrm{Br}$ ): Mixed trans-di-phosphine/NHC palladium complexes, Welton ${ }^{86}$

Caddick and co-workers, ${ }^{87 a}$ in 2001, described the synthesis and ligand reactivity of mixed NHC and phosphine complexes of palladium, Figure 15. They examined the ability of these complexes to promote amination reactions which have indicated that these are extremely good catalysts.

Figure 15, ( $\mathrm{R}_{1}=\mathrm{Bu}^{\mathrm{t}}, 2,6-\mathrm{Pr}_{2}{ }_{2}{ }^{2} \mathrm{R}_{2}=\mathrm{Cy}$, o-tolyl ): Mixed $\mathrm{NHC} /$ phosphine complexes of Pd

For the first time, a monoanionic chelating dicarbene ligand was synthesized in situ by Fehlhammer et al. in 2001. ${ }^{87 \mathrm{~b}}$ Palladium and platinum neutral complexes, Figure 15b, of this ligand as mixed dicarbene / phosphine compound was described in good yields.

Figure 15b, $(\mathrm{M}=\mathrm{Pd}, \mathrm{Pt})$ : A monoanionic chelating dicarbene ligand, Fehlhammer ${ }^{87 \mathrm{~b}}$

In 2002, Grutzmacher and co-workers ${ }^{88}$ synthesized and crystallized the first stable cationic mixed phosphine-carbene gold complex, NHC-Au-P, which expands the class of functionalised carbene complexes, Figure 16.

Figure 16: Cationic mixed phosphine-carbene Au complex, Grutzmacher ${ }^{88}$

In 2002 and 2003, Danopoulos et al. published papers on the synthesis of similar ligands to those reported by Nolan, which included the formation of a series of thermally stable bidentate chelating phosphine-functionalized NHCs ligands and their complexation with $\operatorname{Pd}($ II $) .{ }^{89}$ In these reports, Danopoulos prepared Nolan's ligand by a new method in higher yield. They described the formation of the diphenylphosphine-functionalised NHC complexes of palladium for their salt and Nolan's salt as well. The incorporation of functional groups like phosphine donors into the carbene ligand systems facilitates electronic tuning of the metal coordination sphere. Deprotonation of the imidazolium salt by the base $\mathrm{KN}\left(\mathrm{SiMe}_{3}\right)_{2}$ in THF at $-78{ }^{\circ} \mathrm{C}$ was followed by in situ reaction with the metal precursor, Scheme $2.42,47$ The diisopropyl-phenyl ligand was formed as a stable free carbene at room temperature due to the
two nitrogen bound functional groups. ${ }^{42}$ In 2004, Lee and co-workers reported another high yield synthetic route designed to make chelating phosphine-functionalized imidazolium salts illustrated in Scheme 2 (where $\mathrm{X}=\mathrm{Cl}^{-}$and $\mathrm{Ar}=$ mesityl, benzyl, F-benzyl, MeO-benzyl, naphthalen-1-ylmethyl). ${ }^{46}$

$\mathrm{Ar}=$ mesityl, di-isopropyl phenyl; $\mathrm{X}=\mathrm{Me}, \mathrm{Br}$
Scheme 2: Synthesis of bidentate phosphine-carbene complexes

Grushin and co-workers, ${ }^{90 a}$ in 2003, synthesized and structurally characterized the first aryl-palladium complex containing the $\operatorname{Pr}^{i} N$-heterocyclic carbene ligand and chloro-Pdaryl species, $\left[\left(\mathrm{Pr}^{i}\right) \mathrm{Pd}\left(\mathrm{PPh}_{3}\right)(\mathrm{Ph}) \mathrm{Cl}\right]$, Figure 17a.

Figure 17a: Aryl-palladium complex of mixed P-NHC, Grushin ${ }^{90 a}$

The first example of a mixed carbene/phosphine hydridoplatinum complex had been obtained by Elsevier et al. ${ }^{90 \mathrm{~b}}$ in 2003, Figure 17b. It was generated by using Whiteside's system that reacts selectively with $\mathrm{C}-\mathrm{H}$ bonds in the 2-position of imidazolium salts. This method of $\mathrm{C}-\mathrm{H}$ activation was found to be more effective and gave a very good yield.

Figure 17b: Mixed carbene/phosphine hydridoplatinum complex, Elsevier ${ }^{90 b}$

A report of a new tridentate pincer phosphine- $N$-heterocyclic carbene ligand and the corresponding palladium, silver and ruthenium complexes came from Lee et al. in 2004 and 2005, Figure 18. ${ }^{91 a, b, c}$ This 2P-NHC ligand with alkyl linkers to the imidazolium ring was prepared by transmetallation and direct addition of Pd precursor without the need of a base.

$\mathrm{X}=\mathrm{Cl}, \mathrm{CH}_{3} \mathrm{CN}$, Py
$\mathrm{Z}=\mathrm{Cl}^{-}, \mathrm{BF}_{4}^{-}$

Figure 18: Tridentate pincer of P-NHC, Lee ${ }^{91}$

One of the possible ways to introduce chirality in the $N$-substituents of the NHCs is to use planar chiral ferrocenyl fragments. In the same year of 2004, a chiral $C_{2}$-symmetric tridentate ligand, PCP, where an NHC is combined with two ferrocenyl phosphine units was prepared by Togni and Gischig in a good yield. ${ }^{92 a, b}$ The synthesis and the X-ray crystal structure of a palladium complex of this chiral imidazolium salt was obtained, Figure 18b.

Figure 18b: Tridentate ligand, PCP, Togni ${ }^{92}$

In 2005, Zhou and his group reported in situ production of palladium complexes of bidentate triaryl phosphine-functionalized NHC ligands, Figure 19. ${ }^{93 a, b}$ Their application in palladium-catalyzed Heck reaction showed a high efficiency for the coupling of a wide range of aryl halides with acrylates and the coupling of aryl bromides with styrene derivatives. In these Heck reactions, the introduction of the bulky substituents on the $N$-phenyl ring was found to be beneficial in term of increasing the activity of the Pd catalyst.

Zhou's group was also able to synthesise a pincer chelating PCP ligand analogous to the above ligand but with two arms of diphenylphosphinobenzyl pendant function and without any metal complexation.

Figure 19: (Zhou's: $\mathrm{R}=\mathrm{Ar}, \mathrm{PR}^{`}{ }_{2}=\mathrm{PPh}_{2}$; Lee's: $\mathrm{R}=\mathrm{Me}, \mathrm{PR}^{`}{ }_{2}=\mathrm{PPh}_{2}$ or $\mathrm{PCy}_{2}$ )

A similar bidentate phosphine-functionalized $N$-heterocyclic carbene ligand with a combination of $\mathrm{Pd}(\mathrm{II})$-metal precursor was reported by Lee et al., in 2009. ${ }^{94}$ They prepared
the first example of a hybrid NHC ligand containing a more electron donating $\mathrm{PCy}_{2}$ moiety as well as a complex containing a $\mathrm{PPh}_{2}$ moiety. A series of palladium complexes were synthesized, isolated and crystallized.

Baker et al., ${ }^{95}$ in 2005, obtained and crystallized bidentate (P-NHC) gold complex analogous to Grutzmacher's complex ${ }^{88}$. It was isolated as the hexafluorophosphate salt ( $\mathrm{P}-\mathrm{Au}-$ $\mathrm{NHC})^{+} \mathrm{PF}_{6}{ }^{-}$.

The group of Herrmann, in 2005, prepared and crystallized a cationic monocarbene diphosphine $\mathrm{Ni}($ II $)$ complex by oxidative substitution, Figure $20 .{ }^{96}$

Figure 20: Cationic monocarbene diphosphine Ni(II) complex, Herrmann ${ }^{96}$

Hahn et al., ${ }^{97}$ in 2006, succeeded in obtaining mono- and di-phosphine-functionalized benzo-carbene ligands as bidentate and pincer-type complexes. Pd and Pt complexes with diphosphine moieties were prepared by carbene transfer from the corresponding Ag-complex, via transmetallation, Figure 21.

Figure 21: $(\mathrm{M}=\mathrm{Ag}, \mathrm{Pd}, \mathrm{Pt} ; \mathrm{X}=\mathrm{Cl})$, Bidentate and pincer P-NHC, Hahn ${ }^{97}$

Poli et al., in 2006, described the preparation and characterisation of $\mathrm{Ni}(\mathrm{II})$ complexes bearing a chelating P-NHC ligand where the metal is bonded to a phosphine ligand that contains a pendant imidazolium moiety, Figure $22 .{ }^{12,98}$ However, their attempts to isolate a neutral phosphine-functionalized $N$-heterocyclic carbene complex of nickel(II) were not successful, even though observations agreed with the generation of such carbon-bonded species.

Figure 22: Ni complex of Chelating P-NHC, Poli ${ }^{98}$

In 2007, Lee and co workers ${ }^{99}$ prepared and structurally characterized Ni (II) complexes of two bidentate phosphine/NHC ligands, Figure 23. The nickel bonded with two arms of phosphine moieties as well as the two carbenic carbons which proved to be highly robust in air, which is a desirable property of a catalyst precursor. This Ni complex was found to be a highly effective catalyst for Suzuki cross-coupling.

Figure 23: Ni(II) complexes of two bidentate phosphine/NHC, Lee ${ }^{99}$

In a similar manner to that of Bappert and Helmchen, ${ }^{89}$ Huw Roberts, in 2007, synthesized phosphine-substituted imidazole ligands, Figure 24, and their Ni, Pd and Pt complexes in moderate yields. ${ }^{100}$

Fig 24, (R=Me, Benzyl): Group 10 complexes of bidentate P-NHC, Huw ${ }^{100}$

A (NHC)AgX complex was used as a transmetallating agent to introduce the NHC to a platinum centre in order to form a Pt-complex of this NHC ligand. A complex bearing a coordinated DMSO ligand was formed which was easily replaced by other ligands such as phosphines to give mixed cis-NHC/phosphine and cis-NHC/bis-phosphine complexes. ${ }^{101}$ Rourke and co-workers found, in 2007, that the cis-[(NHC)(DMSO) $\left.\mathrm{PtCl}_{2}\right]$ complex was useful in synthesising mixed ligand complexes. A reaction of triphenyl phosphine, $\mathrm{PPh}_{3}$, with such a complex resulted in the generation of a cis-[(NHC)( $\left.\left.\mathrm{PPh}_{3}\right) \mathrm{PtCl}_{2}\right]$ complex. The reaction of a second equivalent of triphenyl phosphine with the cis-[(NHC) $\left.\left(\mathrm{PPh}_{3}\right) \mathrm{PtCl}_{2}\right]$ complex resulted in the formation of a cationic mixed $\left[\text { cis- }(\mathrm{NHC})\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{PtCl}\right]^{+}$complex, Scheme 3.

Scheme 3: Pt complex of mixed P/NHC, Rourke ${ }^{101}$

A new synthetic strategy by Marinetti et al., ${ }^{102 \mathrm{a}, \mathrm{b}}$ in 2007, allows access to an axially chiral square-planar platinum(II) complexes by combining diphosphine, dppe, and NHC ligand. The reaction was also carried out with chiral bidentate phosphines and achiral NHC ligands in order to generate the corresponding mixed NHC/diphosphine platinum complexes as diastereomeric pairs, Figure 25.

Figure 25: Pt complese of mixed di-P/NHC, Marinetti ${ }^{102}$

Pd complexes of diphenylferrocenylphosphine-functionalized imidazolium salt was prepared in moderate yield by Shi and co-workers in 2008, Figure $26 .{ }^{103}$ This ligand was evaluated and found to be efficient in the palladium-catalyzed amination of aryl halides with a variety of primary and secondary cyclic and acyclic alkyl amines.

Figure 26: Pd complex of bidentate P-NHC, Shi ${ }^{103}$

Fryzuk et al., in 2009, synthesized and structurally characterized a new type of neutral pincer ligand of the PCP type wherein the central carbon donor is a saturated NHC. ${ }^{104}$ The
imidazolium unit is flanked by two phosphine moieties and has $o$-phenylene linkers between the NHC and the phosphine donors. Subsequent reaction with Group 10 metal precursors, (Ni, $\mathrm{Pd}, \mathrm{Pt}$ ), produced the corresponding metal hydride complexes as $\mathrm{PF}_{6}{ }^{-}$salts, $[(\mathrm{PCP}) \mathrm{MH}] \mathrm{PF}_{6}$, in high yields. The incorporation of group 10 metals with the di-o-phenylene-bridged tridentate ligand, PCP, proceeds smoothly to generate a stable square-planar complex, Figure 27.

Figure 27, (M=Ni, Pd, Pt): PCP, Fryzuk ${ }^{104}$

Using more direct method compared to Fryzuk system, Edwards and co-workers, in early 2009, prepared complexes with a facially coordinated macrocyclic $2 \mathrm{P} / \mathrm{NHC}$ ligand, the first macrocycle containing carbene and phosphorus donors. ${ }^{105 a}$ This tridentate $N$-heterocyclic carbene-diphosphine macrocycle ligand was produced by the template controlled linkage of a coordinated diphosphine to a NHC ligand at Mn via nucleophilic displacement of fluoride in 2-fluoroaryl phosphines, Scheme 4. The resultant complex contains two phosphine-phenyl groups and one NHC donor group coordinated to $\mathrm{Mn}(\mathrm{I})$ and $\operatorname{Re}(\mathrm{I})$. The facial incorporation of a tridentate macrocyclic ligand into a metal complex, such as $\mathrm{NHC}-\mathrm{Mn}(\mathrm{CO})_{4} \mathrm{Br},{ }^{105 b}$ may impart interesting properties to a given metal complex since this PCP donor set is restricted to bind in a facial mode (due to the $o$-phenylene linkers restricting the ligand ring size), and thus forcing the remaining coordination sites into mutually cis positions; a configuration required for catalytic applications.

Scheme 4: Mn complex of macrocyclic 2P/NHC, Edwards ${ }^{105}$

Macrocyclic ligands containing both NHC and phosphine donor groups remain very rare. Subsequent to the report of Edwards et. al., Hahn et al., ${ }^{106}$ in 2010, described mixed biscarbene/bisphosphine platinum complexes and the template-controlled preparation of platinum macrocyclic complexes. Their syntheses led to platinum complexes with two transphosphine groups and two trans-coordinated NHC carbene ligands, Figure 28.

Figure 28: Pt complexes of mixed P/NHC and macrocyclic ligands, Hahn ${ }^{106}$

These latter complexes reacted with phosphine ligand, which is capable of bridging to the $\mathrm{NH}, \mathrm{NH}$-stabilized carbene ligands, followed by an intramolecular hydroamination reaction to produce the tetradentate $2 \mathrm{NHC} / 2 \mathrm{P}$ macrocyclic platinum complexes, Figure 28. This template-controlled preparation and crystallization of cationic platinum complexes constitutes the first example of a complex bearing a tetradentate bis-NHC/bis-phosphine macrocycle.

In 2011, Hahn et al. ${ }^{107 \mathrm{a}}$ synthesized and crystallized monodentate NHC-M complexes via an oxidative addition method of the $\mathrm{C}_{1}-\mathrm{Cl}$ bond of a benzimidazolium derivative followed by protonation of the unsubstituted nitrogen atom with an acid, $\mathrm{NH}_{4} \mathrm{BF}_{4}$. This development of a one-pot synthesis for such complexes was used for the coordination of zero-valent Pd and Pt metal precursors having $\mathrm{PPh}_{3}$ ligands. For the Pd complex, NHC-trans-X was obtained, while the oxidative addition for Pt yielded a mixture of cis (major) and trans (minor). Huynh and coworkers achieved a similar result for Pt complex of mixed NHC/mono-phosphine/2-halide, in 2007. ${ }^{107 b}$

Based on benzimidazolium backbone such as in Figure 29, Sakaguchi and Kamisue, in 2011, ${ }^{108}$ designed and synthesized amide-functionalized $N$-heterocyclic carbene (NHC) precursors. By in situ Ag-transmetallation method, they afforded and crystallized mixed $\mathrm{NHC} /$ phosphine complexes with Pd such as $\left[(\mathrm{NHC})\left(\mathrm{PPh}_{3}\right) \mathrm{PdCl}_{2}\right]$ together with a cationic $\left[(\mathrm{NHC})\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{PdCl}\right]^{+} \mathrm{Cl}^{-}$complex. This one-pot procedure, without purification of the NHCAg intermediates, resulted a high yield complexation which expanded the collection of NHC$\mathrm{Pd}(\mathrm{II})$ complexes bearing amide functionalities.

Figure 29: Pd complex of mixed 2P/NHC, Kamisue ${ }^{108}$

Manganese complexes of NHC/phosphine ligands are less common and most of these complexes bear unsaturated imidazolin-2-ylidene ligands. ${ }^{109}$ Attempts by Hahn et al., ${ }^{110}$ in 2011, to synthesise a facial mixed NHC/diphosphine manganese complex were unsuccessful as the $\mathrm{NH}, \mathrm{NH}$-substituted saturated cyclic diaminocarbene and the diphosphine ligands could not be coordinated in the required facial geometry, as was previously observed with other metals, but instead featuring a meridional arrangement of the diphosphine and the NHC ligand, Figure 30.

Figure 30: Mn complex of mixed 2P/NHC, Hahn ${ }^{110}$
In 2012, Xu et al. ${ }^{111}$ synthesised and crystallized two mixed donor NHC/phosphine palladium complexes, Figure 31. These two trans and cis NHC/phosphine palladium(II) complexes have been prepared from the reaction of the corresponding NHC-(dimethoxyphenyl). Single-crystal X-ray analysis confirms there are intermolecular C-H ${ }^{\cdots} \mathrm{X}$ and $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds in such complexes. These complexes were found to be efficient catalysts for the Suzuki reaction of aryl bromides.

Figure 31: $\left(\mathrm{R}=\mathrm{Ph}_{3}, \mathrm{R}^{`}=\left(\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{p}-\mathrm{Me}\right)_{3}\right.$, Pd complex of mixed $\mathrm{P} / \mathrm{NHC}, \mathrm{Xu}^{111}$

Other related iridium complexes of mixed dentate NHC/P are depicted below in Figure 32.

## 1.9: Aims and objectives of this thesis

Transition metal NHC complexes have been applied as homogeneous and heterogeneous catalysts with good results. $N$-heterocyclic carbene/phosphine complexes have been explored by many research groups and have played a role in organometalllic chemistry. This special attention was due to their high thermal and chemical stability and high dissociation energies.

To date, research has mainly focused on chelating $N$-heterocyclic carbene/phosphine ligands with aliphatic backbone functions, leaving chelating $N$-heterocyclic carbene/phosphine ligands with rigid o-phenylene backbone spacers and aryl phosphine donors relatively unexplored. The work presented in this thesis will focus on the synthesis and characterisation of rigid chelating $N$-heterocyclic carbene/phosphine ligands bearing various aliphatic and aromatic substituents and their complexes.

There is an interest in the contribution of bonding properties in a ligand that must bind to mutually cis sites requiring reactive sites to be mutually trans to the carbene's transinfluence or the phosphine's trans-effect. Rigid chelating ligands are favoured in order to minimise side reactions resulting from spectator ligand dissociation. With this aim, I have prepared a series of ligands with rigid o-phenylene backbone spacers and aryl phosphine donors. In this thesis, I describe alkyl phosphine derivatives and synthetic details of this study. Once this ligand synthesis is achieved, the coordination chemistry of the ligand with metals of Group 7, 9, 10 and 11 have been investigated and details of these will be presented. Complexes of this type of ligands are likely to have interesting properties and catalyse a wide range of organic reactions. The design and synthesis of such type of complexes are, therefore, an appealing enterprise. However, the available synthetic methods for such rigid chelating NHC/phosphine ligands and their complexes are low yielding. Consequently, new synthetic methodologies with good yields need to be developed.

Finally, the catalytic properties of such complexes should be investigated in separate study. Also NHC ligands bearing other aliphatic functionalized phosphine groups should be developed and investigated.

## Chapter 2

# Synthesis of an Imidazolium Precursor and Functionalised Phosphine-Imidazolium Salt derivatives as Ligands for the Formation of Metal Complexes 

## 2.1: Introduction

### 2.1.1: Imidazolium Salts

This thesis focuses exclusively on a single NHC precursor and the synthesis of its imidazolium salt and complexes. The approach to the synthesis of phosphine-imidazolium salts, (1, Figure 2.1), involves an in situ coupling reaction of alkyl halides with imidazole.

Figure 2.1: Phosphine-imidazolium salt

Related catalytic amination reactions of aryl halides have been reported by Buchwald ${ }^{1,2}$ and Hartwig. ${ }^{3}$ Palladium and copper have been employed as the catalyst sources in these syntheses. In the synthesis of $\mathbf{1}$, we have utilised all three methodologies. These have been studied as a function of a variety of variables such as temperature, time of reaction, base, ligand, catalyst loading, etc. The copper-catalysed system of Buchwald et al. ${ }^{1}$ was by far the most successful method of the three for the cross-coupling reactions attempted. However, yields were still poor with $34 \%$ maximum isolated yield.

Imidazolium salts can be prepared by reacting the potassium salt of imidazole with one equivalent of primary alkyl halide in a non-polar solvent, to prevent any elimination. ${ }^{5}$ Another equivalent of a different alkyl halide may then be reacted with the resulting $N$-alkylated imidazole in a polar solvent.
The route to synthesise $N$-substituted imidazoles was adapted from Gridnev and Arduengo from the literature method. ${ }^{6,7}$ It sought to build the imidazole ring from the corresponding amine, which proved to be a much more effective method. So, imidazolium salts were formed by converting primary amines to di-imines. ${ }^{677}$ Grubbs et al. reported the synthesis of unsymmetrical $\mathrm{N}, \mathrm{N}$-diaryl imidazolium salts. ${ }^{8}$ Thus, these studies support the indication that it should be possible to synthesise classes of ligands having different alkyl and/or aryl groups at the $\mathrm{N}_{1}$ and $\mathrm{N}_{2}$ positions, and with similar or different functionalities.

The imidazolium salt in this thesis is derived from $N$-substituted imidazole. ${ }^{9}$ This substituted imidazole 2.1 is prepared by the reaction of primary amines, glyoxal and formaldehyde in acidic conditions, Scheme 2.2.

### 2.1.2: Phosphine-imidazolium ligands

In the case of monodentate carbenes, a reductive elimination may occur with cisorientated (to the carbene-carbon) alkyl groups. This decomposition is suggested to be facilitated by distortions (compression) of inter-ligand bond angles and because orbitals of the carbene-carbon and these alkyl groups can overlap easily. ${ }^{10} \mathrm{NHC}$-phosphine complexes have been found to increase the catalytic activity in many reactions such as hydrogenation, carbonylation, hydroformylation, and ring-opening metathesis. ${ }^{11}$

To limit such reductive eliminations, chelating bidentate ligands, especially those bearing rigid linkers forming 6 -membered chelating rings with the metal, would be expected to be less susceptible to reductive elimination than related flexible aliphatic linkers. Thus rigid aryl linker rings would be expected to enhance the complex stability by limiting the linker free movements around the metal centre. Previous work of Nolan and Danopoulos has showed substituted imidazolium ligands with phosphine-alkyl linkers ${ }^{12 \mathrm{a}-\mathrm{b}, 13}$ with and without aryl interspersed in the alkyl linker chains. ${ }^{14,15,16}$ These have been shown to have moderate activity in C-C coupling reactions albeit with some decomposition in chlorinated solvents. ${ }^{13}$ The reported bidentate P-NHC ligands with a linker between the imidazolium ring and the phosphine moiety were found to be unfavourable flexible bridge, which prompted the Edwards-Cavell group to design a rigid linker such as a phenyl ring between the two functional groups so that the chelating ligand will be be unable to rotate freely. Correspondingly, this thesis is focused in synthesising a ligand that has a rigid aryl linker and which forms a 6-membered chelate ring upon coordination with a transition metal.

A rigid bidentate carbene-phosphine coordination mode would be formed by directly connecting an $o$-phenylene ( 1,2 -benzdiyl) ring spacer between the imidazolium core and the phosphine donor. This, in turn, will force the coordinated carbene to tend towards co-planarity (with the chelate ring and coordination plane) instead of being at $\sim 65^{\circ}$ to the coordination plane as is commonly observed. ${ }^{17}$ In this context, the study of complexes of these bidentate carbene-phosphines, i.e. the stability of the carbene-metal bond and ease of dissociation of the phosphine will be of interest. ${ }^{18,19}$

Complexes of chelating carbene-phosphine ligands are known. ${ }^{13,19,20}$ The ligands studied to date are predominantly flexible with aliphatic backbone functions. Phosphine-
imidazolium salts with an aryl linker which forms 7-membered chelate rings have been studied in our group, ${ }^{4,21}$ Figure 2.2, A. Other mixed phosphine-imidazolium salts with alkyl linkers forming 6-membered chelate ring with a metal were synthesised in 2001 by Nolan et al., ${ }^{12}$ Figure 2.2, B.

R=Mes, Dipp

A
B

Figure 2.2

Incorporation of phosphorus donors into aromatic systems by nucleophilic substitution of fluoride in aryl-fluorides has been developed by Edwards et al. in the synthesis of Pmacrocycles. ${ }^{21 b}$ In this reaction, fluoride is an effective leaving group, especially when the 2fluoroaryl function is adjacent to an electron withdrawing centre (e.g. a metal cation or imidazolium core). We have shown that this method does work for imidazole functionalised fluoroarenes although in these earlier attempts in our laboratories to prepare a benzo bridged chelating carbene-phosphine imidazolium salt precursor, phosphonium salts were preferentially formed Scheme 2.1. ${ }^{21}$ An alternative method was adopted in this thesis to synthesise the target where the imidazole ring would be substituted with an alkyl group at the $\mathrm{N}_{1}$ position before nucleophilic substitution of aromatic fluoride with the relevant phosphide nucleophile.

Scheme 2.1: R=cyclohexyl, ${ }^{i} \mathrm{Bu}$

This thesis describes work towards rigid chelating ligands designed to minimise side reactions resulting from spectator ligand dissociation. With this aim, we have prepared a ligand with a rigid $o$-phenylene backbone spacer and alkyl phosphine donors. The work described in this thesis establishes the synthetic methodology and the structure of a number of novel donor phosphine-NHC ligands and complexes. In particular, chelating phosphine-NHC ligands bearing diisopropyl substituents will be focussed upon for the synthesis of metal complexes. A number of chelating phosphine-carbene ligands and their complexes have been synthesised. However, this field is still relatively new and the ligand design and its catalytic aspects have not yet reached full potential. Mixed phosphine-NHC ligand and its complexes were synthesised for study in this thesis.

### 2.1.3: Ligand Structure:

In principle, attaching an aryl ring directly to the imidazole ring will form a rigid chelating phosphine-carbene ligand, as illustrated in Figure 2.3, (A). In these structures, carbene and phosphine donors should work together in a bidentate fashion chelating the metal and forming a 6 -membered chelate ring.

Figure 2.3: Illustration of a rigid chelating phosphine-carbene ligand and complex

A prefix " im " is an abbreviation to denote the substituent's positions on the imidazole ring. As an example, $\left(\mathrm{im}_{2}\right)$ refers to the carbon atom at the 2-position and $\mathrm{im}_{2}-\mathrm{H}$ to the hydrogen on that carbon atom of the imidazole ring. The letter "L" refers to the free ligand which is a phosphine- $N$-heterocyclic carbene (P-NHC) salt. In the crystal structures described herein, the labelling of $\mathrm{C}_{2}$ will be for the carbene's carbon on ligand " L " and $\mathrm{C}_{1}$ for the carbene's carbon of complexes of that ligand, the numbering Scheme adopted for the ligand and complexes are illustrated in Figures 2.3.

## 2.2: Results and discussion

### 2.2.1 Synthesis and characterisation of imidazolium salts (2.2)

The compound 2.1 was synthesised in moderate yields by using the acid catalysed reaction of 2-fluoroaniline, ammonium acetate, glyoxal and formaldehyde Scheme 2.2. The crude solid was washed with water and extracted into diethyl ether or hot hexane to produce the fluoroinated-phenyl imidazole as a light brown oil, 2.1.

The desired imidazolium salts, could be prepared by reacting the $N$-substituted 1-(2fluorobenzene)imidazole with an appropriate alkyl halide. For this study, the $N$-substituted 1-(2-fluorobenzene)imidazole was reacted with methyl iodide and refluxed overnight in THF to give the corresponding imidazolium salt (1-fluorophenyl-3-methyl)imidazolium iodide, 2.2, in almost quantitative yields. $\mathbf{2 . 2}$ was obtained as a tan solid which was moderately soluble in dichloromethane, but poorly soluble in ethers and hydrocarbons. Literature precedence indicates that alkylation with bulkier groups would also be possible enabling a more general synthetic route to be established. ${ }^{22 a, b}$

Scheme 2.2: Synthesis of compounds; imidazole 2.1 and imidazolium salt $\mathbf{2 . 2}$

The imidazole ${ }^{1} \mathrm{H}$ NMR spectrum shows a resonance attributable to the ${ }_{\mathrm{im}} \mathrm{C}_{2}-\mathrm{H}$ proton at 7.71 ppm . In the imidazolium salt 2.2 (carrying the $N$-methyl group), the ${ }^{1} \mathrm{H}$ NMR spectrum for the $\mathrm{im}_{2}-\mathrm{H}$ proton is shifted downfield to 10.14 ppm . The protons of the N methyl group appear as a singlet at 4.24 ppm . In the ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum, the ${ }_{\mathrm{im}} \mathrm{C}_{2}$ carbon
resonance appears at 137.0 ppm . The fluoride atom gives rise to a resonance at approximately -124 ppm in both ligands $\mathbf{2 . 1}$ and $\mathbf{2 . 2}$ in their ${ }^{19} \mathrm{~F}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra.

A halide exchange resin column was used to exchange the counter ion from iodide ( $\mathrm{I}^{-}$), of compound 2.2, to chloride ( $\mathrm{Cl}^{-}$), compound 2.3. A halogen test confirmed a complete exchange to the chloride counter ion.

### 2.2.2: Synthesis and characterisation of functionalised alkyl phosphine-imidazolium salt (2.5)

At the onset of this work, attempts to synthesise imidazole precursors and salts such as (2.1), and (2.2) had been unsuccessful. A key approach was based upon early observations in the nucleophilic displacement of fluoride from aryl-fluoro compounds by Edwards et al., ${ }^{4}$ the fluoro-aryl moiety rather than other halide due to the fact that the fluorine-aryl bond is known to react more readily with potassium diarylphosphide than the bromine-aryl bond, ${ }^{23,24,25}$

In order to substitute the fluoride with alkylphosphide, the latter moiety should undergo a lithiation step. To a solution of $\mathrm{LiAlH}_{4}$, chloro-diisopropylphosphine $\left(\mathrm{ClPPr}^{1}{ }_{2}\right)$, was added drop-wise at room temperature to be left stirring overnight. The work-up was modified from literature ${ }^{17}$ such that addition of distilled water, quenching $\mathrm{LiAlH}_{4}$ by NaOH , and stirring with drying agent. The corresponding diisopropylphosphine, $\operatorname{HPPr}^{2}{ }_{2}$, was collected by distillation at boiling point at $118{ }^{\circ} \mathrm{C}$ showing ${ }^{31} \mathrm{P}$ NMR at $-15.3 \mathrm{ppm} . \mathrm{HPPr}^{i}{ }_{2}$ was then reacted with a strong base, $n$-BuLi, in order to form lithium diisopropylphosphide, $\operatorname{LiPPr}^{i}{ }_{2}$, a better liberated cation to react with the fluoride in the fluorinated phenyl-imidazolium salt, $\mathbf{2 . 2}$ or 2.3. The reaction was carried out in toluene and stirred for about 3-4 days. A white precipitate 2.4, Scheme 2.3, formed which was very air sensitive. Its ${ }^{31} \mathrm{P}$ NMR spectrum shows the absence of $\mathrm{P}-\mathrm{H}$ coupling and a resonance at -1.5 ppm (in toluene) or at -18.4 ppm (in $\mathrm{Et}_{2} \mathrm{O}$ ).

Scheme 2.3: Preparation of lithium diisopropylphosphide 2.4

This lithiated diisopropylphosphide 2.4 in toluene was added to a solution of the fluorinated phenyl-imidazolium salt $\mathbf{2 . 2}$ or $\mathbf{2 . 3}$ at $0^{\circ} \mathrm{C}$. During the course of 3 days reaction between $\mathbf{2 . 2}$
or 2.3 and lithium diisopropylphosphide, the reaction changed from orange to light brown colour, as the lithium diisopropylphosphide was consumed. The solvent was removed under vacuum and MeOH added to quench any unreacted $\mathrm{LiPPr}{ }_{2}{ }_{2} . \mathrm{HPPr}_{2}^{i}$ and any excess of MeOH was then removed under vacuum. Degassed water was added to the crude mixture to dissolve the alkyl phosphinated imidazolium salt which was then extracted into dichloromethane. The volume of DCM extract was reduced under vacuum. Diethyl ether was added to give a precipitate that was washed with a large volume of $\mathrm{Et}_{2} \mathrm{O}$ to give the desired phosphineimidazolium salt 2.5 or 2.6 as a pale brown solid, Scheme 2.4. The reaction was first carried out in different solvents such as THF, $\mathrm{Et}_{2} \mathrm{O}$, DME, and liquid $\mathrm{NH}_{3}$ in the same way described for the synthesis of lithium diisopropylphosphide and ligand 2.5 or 2.6. However, it was found that a higher isolated yield with less impurity was obtained when toluene was used as the solvent. This may be due to the fact that toluene is behaving as a poorer solvent for the lithium salt metathesis product, as well as being less reactive to the lithium phosphide precursor than other solvents. Regardless of the rationalisation, the work-up is cleaner and simpler.

Scheme 2.4: Synthesis of diisopropylphosphine imidazolium salt 2.5

The product was fully characterised by ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\},{ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectroscopy, high resolution mass spectrometry, and elemental analysis. In the ${ }^{1} \mathrm{H}$ NMR spectrum, in $\mathrm{CDCl}_{3}$, the ${ }_{i m} \mathrm{C}_{2}-\mathrm{H}$ proton was observed at 9.62 ppm , the ${ }_{\mathrm{im}} \mathrm{N}_{1}-\mathrm{CH}_{3}$ protons appeared at 4.25 ppm and protons of diisopropyl appears at 0.84 ppm as doublet-of-doublets, Figure 2.4. Protons of the aromatic groups, phenyl and imidazolium rings appear in the range of $7.84-7.27 \mathrm{ppm}$.

Figure 2.4: ${ }^{1} \mathrm{H}-\mathrm{NMR}$ and ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}-\mathrm{NMR}$ spectra, in $\mathrm{CDCl}_{3}$, of ligand 2.5
A singlet resonance peak was observed in the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$-NMR spectrum at -6.8 ppm , in $\mathrm{CDCl}_{3}$, which corresponds to the free phosphine ligand, Figure 2.5. This chemical shift value is up-field of that of $\operatorname{PPr}^{i}{ }_{3}(\delta=21 \mathrm{ppm})$ and somewhat down-field of that of $\operatorname{LiPr}^{i}{ }_{2}(\delta=-18.4$ ppm). Recent related compounds with ortho-substituents to the phosphine reported by Fryzuk et al. ${ }^{26}$ show a shift value at ( -6.4 ppm ) in their ${ }^{31} \mathrm{P}-\mathrm{NMR}$ spectra compared to compound $\mathbf{2 . 5}$.

The ${ }_{i m} \mathrm{C}_{2}$ carbon appeared as singlet at 137.4 ppm in the ${ }^{13} \mathrm{C}$-NMR spectrum, in $\mathrm{CDCl}_{3}$. A mass of 402.3 in the mass spectrum corresponds to the molecular ion and elemental analysis of the ligand is consistent with calculated values validating the formulation.

Crystals suitable for a single crystal X-ray crystallographic determination were obtained upon concentrating a solution of $\mathbf{2 . 5}$ in DCM at $5^{\circ} \mathrm{C}$. The crystal structure and labelling Scheme for $\mathbf{2 . 5}$ is shown in Figure 2.5 (Appendix: Data set 1). The imidazolium proton is orientated in a different direction to the phosphine lone pair with a distance of 3.343(3) $\AA$, probably because of electrostatic repulsion in that region. The ${ }_{i m} \mathrm{C}_{2}-\mathrm{H}$ proton does not interact with the iodine ion, $\mathrm{H}(2)-\mathrm{I}=2.911(5) \AA$, or with any other atom. The average P-C bond length $(1.866 \AA)$ is of a similar average value compared to triisopropylphosphine ${ }^{27}$ (1.862(9) $\AA$ ) and differs slightly in comparison to the related ligand bearing two P-phenyl groups (which is $(1.833 \AA)^{4}$ rather than P-diisopropyl groups in our ligand, 2.5. The average C-P-C bond angle in $2.5\left(100.6(6)^{\circ}\right)$ shows small differences (of about 3 degrees) from that in triisopropylphosphine ${ }^{27}$ and ( 1.5 degrees) than in the diphenylphosphine imidazolium salt. ${ }^{4}$

Figure 2.5: Molecular structure of compound 2.5, ORTEP projection, $40 \%$ probability ellipsoids, in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$, hydrogen atoms are omitted for clarity. (Appendix: Data Set 1)

Table 2.1: Some selected bond lengths ( $(\AA)$ and angles (degrees) for imidazolium salt $\mathbf{2 . 5}$.

| Bond Lengths ( $\AA$ ) |  |  |  | Bond Angles ( ${ }^{0}$ ) |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{C}(2)-\mathrm{N}(1)$ | 1.313(7) | $\mathrm{C}(5)-\mathrm{N}(2)$ | 1.428(7) | $\mathrm{N}(1)-\mathrm{C}(2)-\mathrm{N}(2)$ | 109.6(5) |
| $\mathrm{C}(2)-\mathrm{N}(2)$ | 1.341(7) | $\mathrm{C}(1)-\mathrm{N}(1)$ | 1.460(7) | $\mathrm{C}(2)-\mathrm{N}(2)-\mathrm{C}(5)$ | 126.7(5) |
| $\mathrm{C}(3)-\mathrm{N}(1)$ | 1.388(8) | $\mathrm{C}(10)-\mathrm{P}(1)$ | 1.862(6) | $\mathrm{C}(2)-\mathrm{N}(1)-\mathrm{C}(1)$ | 125.3(5) |
| $\mathrm{C}(4)-\mathrm{N}(2)$ | 1.387(7) | $\mathrm{C}(11)-\mathrm{P}(1)$ | 1.871(7) | $\mathrm{C}(10)-\mathrm{P}(1)-\mathrm{C}(11)$ | 102.7(3) |
| $\mathrm{C}(3)-\mathrm{C}(4)$ | 1.334(8) | $\mathrm{C}(14)-\mathrm{P}(1)$ | 1.863(7) | $\mathrm{C}(10)-\mathrm{P}(1)-\mathrm{C}(14)$ | 97.1(3) |
|  |  |  |  | $\mathrm{C}(11)-\mathrm{P}(1)-\mathrm{C}(14)$ | 102.1(3) |

Some selected bond lengths and angles are collected in Table 2.1. Table 2.2 lists a comparison of bond lengths and angles between the diisopropylphosphine imidazolium salt 2.5., its diphenylphosphine imidazolium salt analogue ${ }^{4}$ and triisopropylphosphine. ${ }^{27}$

Table 2.2: Comparison of bonds and angles
$\left.\begin{array}{|c|c|c|c|}\hline \text { Bond Lengths } \\ \text { \& } \\ \text { Angles }\end{array}\right)$

Crystallography data shows that $\mathrm{C}_{2}-\mathrm{N}_{1}(1.313(7))$ is shorter than $\mathrm{C}_{2}-\mathrm{N}_{2}(1.341(7))$, which indicates lack of charge delocalization. One $\mathrm{N}_{\text {imidazole }}$ atom is positively charged and the carbene proton ( $\mathrm{C}_{2}-\mathrm{H}$ ) is highly deshielded as shown in ${ }^{1} \mathrm{H}-\mathrm{NMR}$. A comparison of ${ }^{1} \mathrm{H}$ chemical shift of the ligand $\mathbf{2 . 5}$ with those of other related compounds is listed in Table 2.3.

Table 2.3: Comparison of ${ }^{1} \mathrm{H}$-NMR of $\mathbf{2 . 5}$ and other compounds

|  <br> Abraham ${ }^{29}$ | 7.74 | 7.13 | 7.13 |
| :---: | :---: | :---: | :---: |

### 2.2.3: Synthesis and characterisation of functionalised alkyl phosphine-imidazolium salt

 (2.6)For the ligand 2.6, Figure 2.6, an analogous procedure to that described for the synthesis of $\mathbf{2 . 5}$ above was followed for the synthesis of phosphine-imidazolium salt 2.6, except that $\mathbf{2 . 3}$ was used where the counter ion of the fluorinated phenyl-imidazolium salt is chloride ( $\mathrm{Cl}-$ ) instead of iodide as in 2.2. The ligand was isolated as a pale brown solid. The product was fully characterised including MS and elemental analysis. The characteristic NMR peaks in $\mathrm{CDCl}_{3}$ were observed at the same positions as in 2.5

Figure 2.6: Ligand of $\mathbf{2 . 6}$

### 2.2.4: Synthesis and characterisation of functionalised alkyl phosphine-imidazolium salt (2.7)

Initial trials to synthesise the salt $\mathbf{2 . 5}$ using THF as a solvent led to the synthesis and crystallization process of phosphine-imidazolium salt 2.7, Figure 2.7. An analogous process to that described for the synthesis of $\mathbf{2 . 5}$ above was followed until the 18 h stirring finished. The supernatant was transferred to another Schlenk and the solvent was concentrated. Drops of $\mathrm{Et}_{2} \mathrm{O}$ were added to the solution and kept in freezer for crystallization at $-35^{\circ} \mathrm{C}$. In the presence of a base during extended reaction times, a by-product was identified and characterised spectroscopically and by X-ray crystallography. A 2-hydroxyethyl substituent has been incorporated into the imidazole ring. Although its formation is currently speculative, this material in which the unique imidazole carbon has been alkylated is probably formed by the attack of the free carbene on THF. The ligand was isolated in poor yield as a pale brown solid. The product was again characterised by ${ }^{1} \mathrm{H}-$ and ${ }^{31} \mathrm{P}\{\mathrm{H}\}$ NMR spectroscopy, high resolution mass spectrometry, and X-ray crystallography.

Figure 2.7: Ligand of 2.7

The characteristic peak of the imidazolium-carbene proton in $\mathrm{CDCl}_{3}$ was not observed in the ${ }^{1} \mathrm{H}$-NMR spectrum indicating its absence in 2.7. X-ray crystallography confirmed the presence of an alcohol group in this position in its place, Figure 2.8. A resonance at 5.35 ppm in the ${ }^{1} \mathrm{H}$-NMR spectrum may be assigned to the alcohol proton, the ${ }_{i m} \mathrm{~N}_{1}-\mathrm{CH}_{3}$ protons appeared at 4.25 ppm and protons of the isopropyl groups appear at 0.96 and 0.84 ppm as a doublet-of-doublets. A singlet was observed in the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$-NMR spectrum at -9.4 ppm in $\mathrm{CDCl}_{3}$, which corresponds to the uncoordinated phosphine, Figure 2.8. This chemical shift is closer to that of ligand $\mathbf{2 . 5}$ as would be expected. A mass of 318.3 in the mass spectrum corresponds to the molecular ion and validates the formulation.

Figure 2.8: ${ }^{1} \mathrm{H}-\mathrm{NMR}$ and ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$-NMR spectra, in $\mathrm{CDCl}_{3}$, of ligand $\mathbf{2 . 7}$

Figure 2.9: ORTEP projection of compound 2.7, in $\mathrm{CDCl}_{3}$. Hydrogen atoms are omitted for clarity (Appendix: Data Set 2)

Crystals suitable for a single crystal X-ray crystallographic determination were obtained upon concentrating a solution of $\mathbf{2 . 7}$ by layering THF / $\mathrm{Et}_{2} \mathrm{O}$ at $-35{ }^{\circ} \mathrm{C}$. The crystal structure and labelling Scheme for $\mathbf{2 . 7}$ is shown in Figure 2.9, which shows a view through the plane of the central benzene ring. It appears that the oxygen of the alcohol group on the imidazole ring is orientated in a different direction to the phosphine lone pair with a distance
of $5.523(0) \AA$, probably because of the electrostatic repulsion between the two lone pairs of both atoms. Selected bond lengths and angles are collected in Table 2.4 (Appendix: Data 2).

Table 2.4: Some selected bond lengths ( $\AA$ ) and angles (degrees) for imidazolium salt $\mathbf{2 . 5}$

| Bond Lengths ( $\AA$ ) |  |  |  | Bond Angles ( ${ }^{0}$ ) |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{C}(3)-\mathrm{N}(1)$ | 1.342(4) | $\mathrm{O}(1)-\mathrm{C}(1)$ | 1.426(4) | $\mathrm{N}(1)-\mathrm{C}(3)-\mathrm{N}(2)$ | 107.5(3) |
| $\mathrm{C}(3)-\mathrm{N}(2)$ | 1.343(4) | $\mathrm{C}(6)-\mathrm{N}(1)$ | 1.470(4) | $\mathrm{N}(1)-\mathrm{C}(3)-\mathrm{C}(1)$ | 127.4(3) |
| $\mathrm{C}(3)-\mathrm{C}(1)$ | $1.499(5)$ | $\mathrm{C}(8)-\mathrm{P}(1)$ | 1.839(3) | $\mathrm{N}(2)-\mathrm{C}(3)-\mathrm{C}(1)$ | 125.1(3) |
| $\mathrm{C}(4)-\mathrm{N}(1)$ | 1.374(4) | $\mathrm{C}(13)-\mathrm{P}(1)$ | 1.863(3) | $\mathrm{C}(8)-\mathrm{P}(1)-\mathrm{C}(13)$ | 101.8(4) |
| $\mathrm{C}(5)-\mathrm{N}(2)$ | 1.380(4) | $\mathrm{C}(16)-\mathrm{P}(1)$ | 1.869(4) | $\mathrm{C}(8)-\mathrm{P}(1)-\mathrm{C}(16)$ | 104.1(3) |
|  |  |  |  | $\mathrm{C}(13)-\mathrm{P}(1)-\mathrm{C}(16)$ | 102.4(7) |

The study of the coordination and reaction chemistry of the phosphine-imidazolium salts $\mathbf{2 . 5}$ or $\mathbf{2 . 6}$ with metal precursors, and the assessment of their complexes is a primary purpose of this research.

### 2.3 Conclusion

An imidazolium salt which combines an imidazolium moiety with an $N$-methyl group and an $N$-functional group side arm, have been synthesised and characterised as a precursor to the corresponding phosphine-NHC ligands. Phosphine-imidazolium derivatives have been formed (2.5) as well as another analogous salt with an alcohol group attached to the carbene position (2.7). The precursor 2.5 has its donor atoms organised in a manner suitable for complex formation with metal precursors and bidentate binding by carbene and phosphine sigma donors. All compounds were characterised by spectroscopic means, including ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ and ${ }^{31} \mathrm{P}-\mathrm{NMR}$ spectroscopies, mass spectrometry and in some cases elemental analysis. Crystallographic determinations were obtained for the phosphine-imidazolium salts, 2.5 and 2.7.

## 2.4: Experimental

### 2.4.1: General comments and materials:

All reactions and subsequent manipulations were carried out using standard Schlenk techniques under an atmosphere of dry argon or nitrogen. Solvents such as tetrahydrofuran (THF), diethyl ether ( $\mathrm{Et}_{2} \mathrm{O}$ ), and $n$-hexane were dried and degassed by refluxing under nitrogen over sodium benzophenone ketyl. Dichloromethane (DCM), ethanol (EtOH), and methanol (MeOH) were pre-dried over $3 \AA$ molecular sieves and subsequently refluxed over calcium hydride under nitrogen. Dimethoxyethane (DME) and toluene were initially refluxed over sodium and distilled under nitrogen before use. All other anhydrous solvents were obtained by distillation from the appropriate drying agents under nitrogen. Deoxygenation of solvents and reagents was carried out by routine air-free techniques (freeze- thaw cycles). Water was deoxygenated by boiling under a purge of nitrogen and cooling to room temperature under nitrogen. Deuterated NMR solvents $\left(\mathrm{CDCl}_{3}\right)$ were purchased from Aldrich or Fisher. All reagents were purchased from commercial sources and used without further purification, unless otherwise stated. Air sensitive compounds and deuterated solvents were degassed or dried ( $3 \AA$ molecular sieves) then stored in Young's Schlenks. Glassware and transfer tubes, cannula etc. were stored at $120{ }^{\circ} \mathrm{C}$ prior to use. $\mathrm{HPPr}_{2}{ }_{2}{ }^{28 a, \mathrm{~b}}$ and $\mathrm{LiPPr}_{2}{ }_{2}^{17}$ were prepared as detailed in the literature.

All ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ and ${ }^{31} \mathrm{P}$ NMR data are given in $\delta / \mathrm{ppm}$. The ${ }^{31} \mathrm{P}$-NMR spectra (referenced to external $85 \% \mathrm{H}_{3} \mathrm{PO}_{4}, \delta=0 \mathrm{ppm}$ ) were measured on a Jeol Lamda Eclipse 300 MHz and a Bruker DPX500 spectrometer operating at 121.7 and 202.5 MHz respectively. ${ }^{19} \mathrm{~F}$ chemical shifts were recorded on Jeol Lamda Eclipse 300 at $282.78 \mathrm{MHz} .{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ spectra (referenced to residual solvent resonances) were recorded on a Bruker DPX400 Avance (operating at $400.8 \mathrm{MHz}\left({ }^{1} \mathrm{H}\right)$ and $100 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right.$ )) and a Bruker DPX500 (operating at 500.13 $\mathrm{MHz}\left({ }^{1} \mathrm{H}\right)$ and $\left.125.75 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right)\right)$ spectrometers referenced to $\mathrm{SiMe}_{4}(\delta=0 \mathrm{ppm}) . J$ values were measured in Hz and peak multiplicities are expressed by the usual conventions ( $\mathrm{s}=$ singlet, $\mathrm{d}=$ doublet, $\mathrm{t}=$ triplet, $\mathrm{m}=$ multiplet, br=broad). Electrospray mass spectrometry (ESMS) was performed on a Waters LCT Premier XE or Waters micromass ZQ instrument. Elemental analyses were performed by MEDAC LTD, UK. Infrared spectra were measured either in solution or in KBr disks on Nicolet 510 FT-IR and JASCO 660 FT-IR spectrophotometers. A glove-box was used for transferring and weighing air sensitive reagents and compounds. Crystal data were obtained on a Bruker Nonius Kappa CCD
diffractometer using graphite monochromatised $\mathrm{MoK} \alpha$ radiation, $\boldsymbol{\lambda}=0.71073 \AA$ equipped with an Oxford Cryostream cooling apparatus.

### 2.4.2 Preparation of compounds:

The following compounds were prepared by modification of a literature recipe:
1-(2-Fluorobenzene)imidazole (2.1) ${ }^{4,21}$
(1-Fluorobenzene-3-methyl)imidazolium iodide (2.2) ${ }^{4,21}$

Preparation of 1-(2-fluorobenzene)imidazole ( 2.1 ):

A mixture of formaldehyde ( 10.7 ml of $37 \% \mathrm{sol}^{\mathrm{n}}, 0.143 \mathrm{~mol}$ ), glyoxal $(16.4 \mathrm{ml}$ of 40 $\% \operatorname{sol}^{\mathrm{n}}, 0.143 \mathrm{~mol}$ ) and glacial acetic acid ( 35 ml ) was heated to $70{ }^{\circ} \mathrm{C}$. To the hot solution was added drop-wise, with stirring, over a period of 3 h . a solution of $\mathrm{NH}_{4} \mathrm{OAc}(11.0 \mathrm{~g}, 0.143$ mol ) and 2-fluoroaniline ( $13.8 \mathrm{ml}, 0.143 \mathrm{mmol}$ ) in $\mathrm{H}_{2} \mathrm{O}(6 \mathrm{ml})$ and glacial acetic acid ( 30 ml ). The solution, which rapidly became orange/red, was stirred for 12 h . The solution was cooled to ambient temperature, then added drop-wise with stirring to a suspension of $\mathrm{NaHCO}_{3}$ ( $151.00 \mathrm{~g}, 1.80 \mathrm{~mol}$ in $\mathrm{H}_{2} \mathrm{O}(1 \mathrm{~L})$. The solution was made alkaline to pH 9 with NaOH , and the resultant solid was then filtered off on a Buchner funnel and washed with $\mathrm{H}_{2} \mathrm{O}(3 \times 50 \mathrm{ml})$ before being dried by suction on the frit. The dry solid was extracted with hot hexane ( $6 \times 200$ $\mathrm{ml})$ and filtered. The solvent was removed under vacuum to give the product as a yellow oil. Yield ( $9.11 \mathrm{~g}, 40 \%) .{ }^{1} \mathrm{H} \operatorname{NMR}\left(400.13 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): 7.71\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{im}_{1}\right), 7.20\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{im}_{2}\right)$, $7.13\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{im}_{3}\right), 7.33-7.12\left(\mathrm{~m}, 4 \mathrm{H}, \mathrm{Ar}^{\mathrm{H}}\right.$ ).

## (1-fluorobenzene-3-methyl)imidazolium iodide ( 2.2 ):

A mixture of 1-(2-fluorobenzene)imidazole (2.1) (4.50 g, 27.7 mmol ) and iodomethane ( $11.8 \mathrm{~g}, 83.3 \mathrm{mmol}$ ) in THF ( 40 ml ) was gently refluxed for 12 h . During the reaction a pale yellow solid was formed. The solid was collected by filtration, washed with several portions of THF, and dried under vacuum to give the product as an off-white solid. Yield ( $8.18 \mathrm{~g}, 97 \%$ ). ${ }^{1} \mathrm{H}$ NMR ( $400.13 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): $10.14\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{im}_{\mathrm{im}}\right.$ ), $7.95(\mathrm{~s}, 1 \mathrm{H}$, ${ }_{\mathrm{im}} \mathrm{H}_{2 / 3}$ ), $7.90\left(\mathrm{t}, \mathrm{J}=7.8 \mathrm{~Hz}, 1 \mathrm{H},{ }_{\mathrm{Ar}} \mathrm{H}\right)$, $7.62\left(\mathrm{~s}, 1 \mathrm{H},{ }_{\mathrm{im}} \mathrm{H}_{2 / 3}\right), 7.50\left(\mathrm{~m}, 1 \mathrm{H},{ }_{\mathrm{Ar}} \mathrm{H}\right), 7.35-722(\mathrm{~m}, 2 \mathrm{H}$, ${ }_{\mathrm{Ar}} \mathrm{H}$ ), 4.24 ( $\mathrm{s}, 3 \mathrm{H}, \mathrm{Me}$ ). ${ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): 155.82 ( $\mathrm{s}, \mathrm{C}$ ), 153.3 ( $\mathrm{s}, \mathrm{C}$ ), 137.0 (s, CH ), 132.4 (d, J=8 ,CH), 126.2 (d, J=5, CH), 124.7 (,$~ C H$ ), 122.7 (d, J=4, CH), 122.3 (d, $\mathrm{J}=11, \mathrm{CH}$ ), 117.6 (d, J=19, CH), 37.9 (s, Me). MS (ES+), M/z: $177.1[\mathrm{M}]{ }^{+} .{ }^{19} \mathrm{~F}$ NMR (282.78 MHz, $\mathrm{CDCl}_{3}, \delta$ ): -124

## (1-fluorobenzene-3-methyl)imidazolium chloride ( 2.3 ):

Dissolving the off-white (1-Fluorobenzene-3-methyl)imidazolium iodide (2.2) in MeOH and then passing it once through a $\mathrm{Cl}^{-}-$exchange resin column to ensure complete conversion of the counter ion from iodide to chloride.

## Preparation of Lithium diisopropylphosphide $\left[\operatorname{LiP}\left(\operatorname{Pr}^{\mathbf{i}}\right)_{2}\right]$ ( 2.4 ):

Diisopropylphosphine $\operatorname{HPPr}^{i}{ }_{2}(0.48 \mathrm{~g}, 4.04 \mathrm{mmol})$ was deprotonated by $n-\mathrm{BuLi}$
$(1.93 \mathrm{M}, 2.11 \mathrm{ml}, 4.04 \mathrm{mmol})$ in toluene or diethylether $(40 \mathrm{ml})$ at $-78^{\circ} \mathrm{C}$ and stirring for about 3-4 days would give a white precipitate. Solvent then decanted and the solid was washed twice by toluene. It resulted in a high yield air sensitive white compound which was kept in a Schlenk in a glove box. $\mathrm{A}^{31} \mathrm{P}-\mathrm{NMR}$ peak shows at -18.4 (in $\mathrm{Et}_{2} \mathrm{O}$ ).

## 1-Benzene-o-diisopropylphosphine-3-methyl)imidazolium iodide (2.5 ):

To (1-fluorobenzene-3-methyl)imidazolium iodide (2.2) (1.23 g, 4.04 mmol ) in toluene $(40 \mathrm{ml})$ at $0{ }^{\circ} \mathrm{C}$, as a ratio of $1: 1$, was added 1 mol equivalent of $\mathrm{LiP}\left(\operatorname{Pr}^{\mathrm{i}}\right)_{2}$, and allowed to stir for 2-3 days at room temperature. The solution gave a graduate change in colour from tan to orange. The solvent was then decanted and removed under vacuum to give a light brown solid. Methanol ( 2 ml ) was added to quench excess phosphide $\left[\operatorname{LiP}\left(\operatorname{Pr}^{\mathrm{i}}\right)_{2}\right]$; the methanol and any excess $\operatorname{HP}\left(\operatorname{Pr}^{\mathrm{i}}\right)_{2}$ were then removed under vacuum. Degassed water was added to the residue and the free ligand extracted into DCM ( $3 \times 10 \mathrm{ml}$ ). The volume of the DCM was removed in vacuo to give the product as an orange-brown precipitate. The solid was washed with $\mathrm{Et}_{2} \mathrm{O}(3 \times 10 \mathrm{ml})$ and then EtOH was added to assist in the removal of water traces leaving the product as a pale brown solid. Single crystals were obtained upon concentrating a solution of 2.5 in DCM at $5{ }^{\circ} \mathrm{C}$. Yield ( $0.1 \mathrm{~g}, 5 \%$ ). ${ }^{1} \mathrm{H}$ NMR ( $500 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): $9.62(\mathrm{~s}$, $1 \mathrm{H},{ }_{i m} \mathrm{H}_{2}$ ), $7.84\left(\mathrm{~s}, 1 \mathrm{H},{ }_{i \mathrm{im}} \mathrm{H}_{3 / 4}\right), 7.58\left(\mathrm{~m}, 4 \mathrm{H}, \mathrm{H}_{\mathrm{Ar}}\right), 7.27\left(\mathrm{~s}, 1 \mathrm{H},{ }_{\mathrm{im}} \mathrm{H}_{3 / 4}\right), 4.25(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Me}), 2.01$ $\left(\mathrm{m}, 2 \mathrm{H}, \mathrm{H}_{11 / 14}\right), 0.96\left(\mathrm{dd}, 6 \mathrm{H}, \mathrm{J}=7.0,16.0 \mathrm{~Hz}, \mathrm{CH}_{3}\right), 0.84\left(\mathrm{dd}, 6 \mathrm{H}, \mathrm{J}=7.0,12.4 \mathrm{~Hz}, \mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C}$ NMR (125.75 MHz, CDCl 3 , ס): 140.4 (d, J=23.75 , C), 137.4 (s, CH), 134.0 (d, J=3.75 , CH), 133.5 (d, J=28.75, C), 130.9 (d, J=41.25, CH), 127.2 (d, J=2.5, CH), 124.4 (d, J=3.75, CH), 123.8 ( $\mathrm{s}, \mathrm{CH}$ ), 37.8 ( $\mathrm{s}, \mathrm{Me}$ ), 24.2 (d, J=11.25, CH), 20.1 (d. J=18.75, $\mathrm{CH}_{3}$ ), 19.9 (d, J=8.75, $\mathrm{CH}_{3}$ ). ${ }^{31} \mathrm{P}$ NMR ( $121.7 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): -6.8. MS (ES+), M/z: $274.3[\mathrm{M}]^{+}$. Elemental Analysis: $\mathrm{C}_{16} \mathrm{H}_{24} \mathrm{~N}_{2} \mathrm{PI}$, Calculated: C: 47.77; H: 6.01; N: 6.96; Found: C: 47.3; H: 6.0; N, 6.8 .

## (1-Benzene-o-diisopropylphosphine-3-methyl)imidazolium chloride (2.6):

2.6 was prepared following the same procedure used for the preparation of compound (2.5) except that the precursor (1-fluorobenzene-3-methyl)imidazolium chloride (2.3) was used instead of (1-fluorobenzene-3-methyl)imidazolium iodide (2.2).

## (1-Benzene-o-diphenylphosphine-2-(propan-2-ol)-3-methyl) imidazolium iodide (2.7):

$\mathbf{2 . 7}$ was prepared following the same procedure as for 2.5, except that THF was used as the reaction solvent and for crystallization. After 18 h stirring, the supernatant was filtered and concentrated in vacuo. Drops of $\mathrm{Et}_{2} \mathrm{O}$ were added by slow diffusion to the tetrahydrofuran (THF) solution to achieve stauration, and the resulting solution was cooled $\left(-35^{\circ} \mathrm{C}\right)$ to give 2.7 which was isolated in poor yield as a pale brown crystalline solid. ${ }^{1} \mathrm{H}$ NMR $(400 \mathrm{MHz}$, $\left.\mathrm{CDCl}_{3}, \delta\right): 7.84\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{im}_{4 / 5}\right), 7.58\left(\mathrm{~m}, 4 \mathrm{H}, \mathrm{H}_{\mathrm{Ar}}\right), 7.27\left(\mathrm{~s}, 1 \mathrm{H},{ }_{\mathrm{im}} \mathrm{H}_{4 / 5}\right), 5.35(\mathrm{~s}, 1 \mathrm{H}, \mathrm{OH}), 4.25$ (s, 3H, Me), $2.01\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{H}_{13 / 16}\right), 1.55\left(\mathrm{~m}, 1 \mathrm{H}, \mathrm{H}_{1}\right), 1.10\left(\mathrm{~m}, 3 \mathrm{H}, \mathrm{CH}_{3}\right), 0.96(\mathrm{dd}, 6 \mathrm{H}, \mathrm{J}=7.0$, $16.0 \mathrm{~Hz}, \mathrm{CH}_{3}$ ), $0.84\left(\mathrm{dd}, 6 \mathrm{H}, \mathrm{J}=7.0,12.4 \mathrm{~Hz}, \mathrm{CH}_{3}\right.$ ). ${ }^{31} \mathrm{P}-\mathrm{NMR}\left(121.7 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right.$ ): -9.4. MS (ES+), M/z: 318.3 [M] ${ }^{+}$.

## Chapter 3

Synthesis of NHC-Phosphine Complexes of Metals of Groups 11, 10, Ir and Mn

## 3.1: Introduction

There are many methods for the preparation of metal complexes of N -heterocyclic carbenes including in situ deprotonation of ligand precursors and transmetallation which have both proved successful in the formation of carbene complexes. The imidazolium salt used in these reactions will not form isolable 'stable' carbenes in order to react directly with metal precursors. However a suitable base (such as potassium bis(trimethylsilyl)amide) can be used to form the NHC in situ with the appropriate metal precursors without isolating the free carbene. In this chapter, all phosphine-NHC complexes are formed either by in situ deprotonation or transmetallation.

NHC complexes are known to support catalysis due to the strong metal-carbon bonds which for some metals may be more robust (less labile) than the more widely used phosphines. The strength of the metal-carbon sigma bond in NHC carbene complexes leads to carbenes having a strong trans influence, whereas phosphines are known to have a strong trans effect (especially for good $\pi$-acceptor phosphines). A good trans effect from the 'spectator ligand' is helpful in catalysis since it helps labilise ligands in the active site, whereas the robustness of carbenes may help to enhance the stability of the catalyst. A combination of both carbene and phosphine in one skeleton may enhance these catalytic activities and introduce new properties of interest. This chapter is mainly concerned with complexation of the new chelating carbene-phosphine ligand discussed in chapter 2 with the following metals of Groups 7, 10 and 11: $(\mathrm{Au}(\mathrm{I}), \mathrm{Ag}(\mathrm{I}), \mathrm{Cu}(\mathrm{I})),(\mathrm{Ni}(\mathrm{II}), \mathrm{Pd}(\mathrm{II}), \mathrm{Pt}(\mathrm{II})), \mathrm{Mn}(\mathrm{I})$ and $\operatorname{Ir}(\mathrm{I})$. ${ }^{*}$

## 3.2: Results and discussion of NHC-phosphine complexes of group 11:

### 3.2.1: Au Complex

## Via Free Carbene:

$\mathrm{Au}(\mathrm{I})$ complex was prepared from $\left(\mathrm{Me}_{2} \mathrm{~S}\right) \mathrm{AuCl}$, by reaction with the free carbene formed by addition of base to the phosphine-imidazolium salt, 2.5, and was isolated as a light brown solid, as the mono-(phosphine-NHC) Au(I) complex, 3.1, Scheme 3.1.

[^0]

Scheme 3.1: Formation of $\mathrm{Au}(\mathrm{I})$-complex, 3.1, via free carbene

Characteristic changes were observed in both the ${ }^{1} \mathrm{H}$ and ${ }^{31} \mathrm{P}-\mathrm{NMR}$ spectra, Figure 3.1, along with satisfactory accurate mass spectrometry data, the spectroscopic data confirmed the formation of the mono-ligand complex 3.1. The coordinated phosphine resonance appeared in the ${ }^{31} \mathrm{P}-\mathrm{NMR}$ spectrum, in $\mathrm{CDCl}_{3}$, as a singlet at 47.8 ppm , displaying a considerable downfield coordination shift from the corresponding free ligand peak (which appears at -6.8 $\mathrm{ppm})$. The chemical shift value of the coordinated phosphine was in the same range as that of related complexes. ${ }^{1,2}$ The spectrum showed no sign of un-coordinated phosphorus atoms indicating that the carbene-phosphine ligand binds the metal centre as a chelate, as well as, the absence of imidazolium proton peak at -9.6 ppm .

Figure 3.1: ${ }^{1} \mathrm{H}-\mathrm{NMR}$ and ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}-\mathrm{NMR}$ spectra, in $\mathrm{CDCl}_{3}$, of Au-complex, 3.1

In the mass spectrum, the highest fragment peak was observed at 745.29 and corresponds to the molecular ion, $[\mathrm{M}]$, of the mono-(phosphine-NHC) $\mathrm{Au}(\mathrm{I})$ chloro complex.

### 3.2.2: Ag complex

The synthesis of $\operatorname{Ag}(\mathrm{I})$ complex, 3.2, was achieved via the reaction of a half molar equivalent of silver oxide, $\mathrm{Ag}_{2} \mathrm{O}$, with one equivalent (i.e. a $1: 1 \mathrm{Ag}$ :ligand ratio) of the corresponding phosphine-imidazolium salt, 2.5, in the presence of degassed $4 \AA$ molecular sieves, following the method of Wang and Lin. ${ }^{3}$ Half the equivalent of $\mathrm{Ag}_{2} \mathrm{O}$ with the salt was enough to cause disappearance of the ${ }_{\mathrm{im}} \mathrm{C}_{1}-\mathrm{H}$ proton peak in the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum, as the observations reported by Cavell ${ }^{4}$ and Helmschen et al. ${ }^{5}$ The isolation of the $\mathrm{Ag}(\mathrm{I})$ complex was achieved by work-up with DCM and the bis-(phosphine-NHC) $\operatorname{Ag}(\mathrm{I})$ complex, 3.1, was isolated as a light brown solid in yield of $80 \%$, Scheme 3.2.

Scheme 3.2: Formation of Ag-complex, 3.2,

The product, $\mathrm{Ag}(\mathrm{I})$ complex 3.2, was characterised by ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C},{ }^{31} \mathrm{P}$ NMR spectroscopies and high resolution mass spectrometry. The ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum of 3.2, in $\mathrm{CDCl}_{3}$, clearly indicates the coordination of the carbene to the silver by the absence of the distinctive carbene proton, $\mathrm{im}_{1} \mathrm{C}_{1}-\mathrm{H}$, which appears at 9.62 ppm in the precursor, phosphineimidazolium salt, 2.5, Figure 3.2A. In the ${ }^{13} \mathrm{C}$-NMR spectrum, a singlet peak for the carbene's carbon, $\mathrm{im}_{1}$, was observed at 181.45 ppm , which is consistent with this type of carbon atom. A characteristic singlet resonance was observed at 5.4 ppm in the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$-NMR spectrum, in $\mathrm{CDCl}_{3}$, Figure 3.2A. This chemical shift in the bis-(phosphine-NHC) $\mathrm{Ag}(\mathrm{I})$ complex is shifted downfield compared to the corresponding free ligand (which appears at -6.8 ppm ) but is close to the value observed in a similar complex synthesised by Helmschen et al. ${ }^{5}$

Figure 3.2A: ${ }^{1} \mathrm{H}-\mathrm{NMR}$ and ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$-NMR spectra, in $\mathrm{CDCl}_{3}$, of Ag-complex, 3.2

The spectrum showed no sign of free, un-coordinated phosphorus atoms indicating that both carbene and phosphorus donors are coordinated to the metal centre in a chelating configuration. At low temperatures, the ${ }^{31} \mathrm{P}-\mathrm{NMR}$ spectrum of the Ag complex exhibits coupling to both ${ }^{109} \mathrm{Ag}$ and ${ }^{107} \mathrm{Ag}$ isotopes; ${ }^{1} J\left({ }^{109} \mathrm{Ag},{ }^{31} \mathrm{P}\right)=259 \mathrm{~Hz}$ and ${ }^{1} J\left({ }^{107} \mathrm{Ag},{ }^{31} \mathrm{P}\right)=227$ Hz indicating that the complex is not labile on the NMR timescale, Figure 3.2B. A coupling pattern to ${ }^{109} \mathrm{Ag}$ or ${ }^{107} \mathrm{Ag}$ was not observed at room temperature. At room temperature, in $\mathrm{CDCl}_{3}$, there was only one fairly sharp signal. At $-40{ }^{\circ} \mathrm{C}$, the ${ }^{31} \mathrm{P}$ signal of $\mathbf{3 . 2}$ clearly splits into two broad signals which was interpreted as two doublets due to the coupling to both silver isotopes, ${ }^{1} J\left({ }^{31} \mathrm{P},{ }^{109} \mathrm{Ag}\right)$ and ${ }^{1} J\left({ }^{31} \mathrm{P},{ }^{107} \mathrm{Ag}\right)$, both of which have a spin of $1 / 2$ and are therefore NMR receptive. ${ }^{6 \mathrm{a}, \mathrm{b}}$ From the measured values of the coupling constants (259 and 227 Hz ), the magnetogyric ratio is 259/227=1.14 which matches almost exactly the relation of the magnetogyric ratio of the two silver isotopes: $\gamma\left({ }^{109} \mathrm{Ag}\right) / \gamma\left({ }^{107} \mathrm{Ag}\right)=1.15 \cdot{ }^{7 \mathrm{a}, \mathrm{b}}$ At low temperatures, it was possible to see the coupling between silver and phosphorus. This is a good indication that the splitting results from the ${ }^{1} J$ coupling of phosphorus to the silver isotopes. ${ }^{6 \mathrm{a}, \mathrm{b}}$ The mass spectrometry data showed a peak, $655.2[\mathrm{M}-\mathrm{H}]^{+}$, corresponding to the bis-ligand-silver complex. Another molecular mass fragment ( 671.2 amu attributed to $[\mathrm{M}+\mathrm{O}]^{+}$) indicates that the complex is sensitive to oxidation. A fragment peak observed at 360.6 amu may be attributed to the counter ion of the complex, $\mathrm{AgI}_{2}{ }^{\ominus}$. However, the structures drawn in Scheme 3.2 does not confirm that is the actual structure for the silver complex as it is difficult to ascertain the precise formula of such complexes without X-ray crystallography.

Figure 3.2B: ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$-NMR spectra, in $\mathrm{CDCl}_{3}$, of Ag-coupling for complex 3.2

### 3.2.3: Cu complex

## A. Via Free Carbene:

The chelating phosphine- $\mathrm{NHC} \mathrm{Cu}(\mathrm{I})$ complex was synthesised in an analogous manner to other group 10 complexes via the formation of the free carbene. The free carbene was generated in situ by the equimolar reaction of the phosphine-imidazolium salt, $\mathbf{2 . 5}$, with the base, $\mathrm{KN}\left(\mathrm{SiMe}_{3}\right)_{2}$ immediately before being transferred into a solution containing one equivalent of the copper precursor, $\left[\mathrm{Cu}(\mathrm{MeCN})_{4}\right] \mathrm{BF}_{4}$, in a THF. The bis-(phosphine-NHC) $\mathrm{Cu}(\mathrm{I})$ complex, 3.3, was isolated by extraction into dichloromethane as an off--white solid, Scheme 3.3.

Scheme 3.3: Formation of Cu-complex, 3.3, via free carbene

The $\mathrm{Cu}(\mathrm{I})$ Complex, 3.3 was characterised by ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ and ${ }^{31} \mathrm{P}-\mathrm{NMR}$ spectroscopies and high resolution mass spectrometry. The absence of the ${ }_{i m} \mathrm{C}_{1}-\mathrm{H}$ proton from the ${ }^{1} \mathrm{H}$-NMR spectrum, in $\mathrm{CDCl}_{3}$, indicated the formation of the carbene-copper bond, Figure 3.3. In the ${ }^{13} \mathrm{C}$-NMR spectrum, in $\mathrm{CDCl}_{3}$, a singlet peak for the carbene carbon, ${ }_{\mathrm{im}} \mathrm{C}_{1}$, was observed at 189.14 ppm , consistent with related NHC carbene complexes. The ${ }^{31} \mathrm{P}-\mathrm{NMR}$ spectrum of 3.3, in $\mathrm{CDCl}_{3}$, showed a downfield shift from -6.8 ppm in the phosphine-imidazolium salts to 3.8 ppm, indicating that the phosphine was coordinated to the metal centre, Figure 3.3, and that the ligand is in a chelating configuration. The mass spectrometry data for $\mathbf{3 . 3}$ only shows one peak at a molecular mass of 611.1 corresponding to the ion, $\mathrm{M}^{+}-\mathrm{H}^{+}$for the bisligand-copper complex. The observed elemental analytical data is consistent with the formulation.

Figure 3.3: ${ }^{1} \mathrm{H}$-NMR and ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$-NMR spectra, in $\mathrm{CDCl}_{3}$, of Cu -complex, 3.3

## B. Via Transmetallation:

The synthesis of the phosphorus-NHC cupper(I) complex $\mathbf{3 . 3}$ was also achieved via transmetallation from the corresponding silver(I) complex $\mathbf{3 . 2}$ by reaction with the copper metal precursor, $\left[\mathrm{Cu}(\mathrm{MeCN})_{4}\right] \mathrm{BF}_{4}$ in dichloromethane. Silver iodide precipitated during the reaction indicating that transmetallation reaction had occurred and the copper complex product (3.3) was isolated as a tan solid, Scheme 3.4.

Again, this product was characterised by ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C},{ }^{31} \mathrm{P}-\mathrm{NMR}$ spectroscopies and high resolution mass spectrometry which confirmed the formation of 3.3. Attempts to grow crystals suitable for X-ray crystallography were unsuccessful.

Scheme 3.4: Formation of Cu-complex, 3.3, via transmetallation

## 3.3: Results and discussion of NHC-phosphine complexes of group 10:

### 3.3.1: Ni Complex

## Via Free Carbene:

The synthesis of a phosphine-NHC nickel complex was achieved via the formation of the free carbene generated in situ by adding a base to the phosphine-imidazolium salt. The free chelating carbene ligand was then trapped with a suitable nickel precursor $\left(\mathrm{NiCl}_{2} . \mathrm{DME}\right)$ to form the product complex, bis-(phosphine-NHC) $\mathrm{Ni}(\mathrm{II}), 3.4$, which was isolated and recrystallized from EtOH as a yellow solid in $32 \%$ yield, Scheme 3.5. Using $\mathrm{KN}\left(\mathrm{SiMe}_{3}\right)_{2}$ as a base in the deprotonation of imidazolium salt was very effective due to the fact that this base is strong enough to deprotonate a range of imidazolium salts cleanly. ${ }^{8,9}$

Scheme 3.5: Formation of Ni-complex, 3.4, via free carbene

The product was fully characterised by ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C},{ }^{31} \mathrm{P}-\mathrm{NMR}$ spectroscopies, high resolution mass spectrometry, and by an X-ray crystallographic determination. In the ${ }^{1} \mathrm{H}$ NMR spectrum, in $\mathrm{CD}_{3} \mathrm{CN}, 3.4$ shows an absence of the ${ }_{i m} \mathrm{C}_{1}-\mathrm{H}$ proton indicating the coordination of the carbene to the nickel metal centre. A more pronounced (than in the group 11 metal complexes) coordination chemical shift was observed in the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$-NMR spectrum, in $\mathrm{CD}_{3} \mathrm{CN}$, which appeared as a singlet at 36.9 ppm , Figure 3.4. The spectrum showed no sign of free phosphorus atoms again indicating complete coordination of the ligand to the metal centre in a chelating fashion. Since the nickel complex is doubly charged, a molecular mass of 303.13 in the mass spectrum corresponds to the molecular ion validating the formulation. Other peaks also occur at mass values consistent with this formulation.

Figure 3.4: ${ }^{1} \mathrm{H}$-NMR and ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$-NMR spectra, in $\mathrm{CD}_{3} \mathrm{CN}$, of Ni-complex, 3.4

Crystals suitable for a single crystal X-ray crystallographic determination were obtained upon saturating a solution of nickel complex 3.4 in EtOH at $5^{\circ} \mathrm{C}$. The crystal structure and labelling Scheme for $\mathbf{3 . 4}$ is shown in Figure 3.5. Complex $\mathbf{3 . 4}$ exhibits a squareplanar geometry where carbene is trans to carbene and phosphorus is trans to phosphorus. The square plane is distorted around the nickel metal centre, the distortion being manifested by a significant deviation of the C-Ni-C angle, (162.9 $)$, and by the P-Ni-P angle, ( $150.5^{\circ}$ ), from the ideal angle of $180^{\circ}$; the $\mathrm{C}-\mathrm{Ni}-\mathrm{C}$ angle is closer to linearity than is the $\mathrm{P}-\mathrm{Ni}-\mathrm{P}$ angle. In 3.4, the $\mathrm{Ni}-\mathrm{C}(1), \mathrm{Ni}-\mathrm{C}(17), \mathrm{Ni}-\mathrm{P}(1)$ and $\mathrm{Ni}-\mathrm{P}(2)$ bond lengths are $1.880(7) \AA, 1.908(7) \AA$, $2.222(0) \AA$, and $2.221(6) \AA$ respectively, and are close to related complexes. ${ }^{12,13}$

The six-membered rings of the two chelating ligands with the metal centre are twisted; the metrical parameters of this Ni-complex, Table 3.1, are similar to those of related Ni-P-NHC complex structures, Figure 3.6 (A \& B) reported by Man Lee ${ }^{10}$ and subsequently by Fryzuk ${ }^{11}$.

Figure 3.5: Molecular structure of Ni-complex (ORTEP projection of compound 3.4, in $\mathrm{C}_{2} \mathrm{D}_{5} \mathrm{OD}, 40 \%$ probability ellipsoids, hydrogen atoms are omitted for clarity) (Appendix: Data Set 3)

Figure 3.6

From the crystal data, the $\mathrm{Ni}-\mathrm{C}$ bonds are shorter than the $\mathrm{Ni}-\mathrm{P}$ bonds. This may indicate the smaller covalent radius of carbon but also may reflect that NHC ligands stronger $\sigma$-donors than trialkylphosphines. ${ }^{2}$ Angles within the imidazole rings, $\mathrm{N}(1)-\mathrm{C}(1)-\mathrm{N}(2)$, 104.1(6) ${ }^{\circ}$, and $\mathrm{N}(3)-\mathrm{C}(17)-\mathrm{N}(4), 105.7(6)^{\circ}$, are within the expected range of $101^{\circ}-106^{\circ} .^{14}$ Selected bond lengths and angles are presented in Table 3.2.

Table 3.1: Comparison of angles and lengths of complex 3.4 with Lee's and Fryzuk's complexes.

|  | Complex 3.4 | Man Lee | Fryzuk |
| :---: | :---: | :---: | :---: |

### 3.3.2: Pd complex:

The synthesis of the phosphorus-NHC palladium complex was achieved from the palladium precursors, $\left[\mathrm{PdCl}_{2}(\mathrm{COD})\right]$ or $\left[\mathrm{Pd}(\mathrm{OAc})_{2}\right]$ by transmetallation and also by reaction with the free carbene following the same synthetic approach used in the synthesis of the Nicomplex 3.4. Ligand 2.5 is used with $\left[\mathrm{PdCl}_{2}(\mathrm{COD})\right]$ and ligand 2.6 used with $\left[\mathrm{PdCl}_{2}(\mathrm{COD})\right]$ or $\left[\mathrm{Pd}(\mathrm{OAc})_{2}\right]$ to form the same Pd -complex. The Ag-complexes reacted smoothly with Pd precursors such as $\left[\mathrm{PdCl}_{2}(\mathrm{MeCN})_{2}\right],[\mathrm{PdMeCl}(\mathrm{COD})],\left[\mathrm{PdCl}_{2}(\mathrm{COD})\right]$ to give the carbenephosphine complexes via transmetallation. ${ }^{15}$

## A. Via Free Carbene:

The chelating phosphine-NHC Pd(II) complex was prepared by an analogous method to the Ni complex via the formation of the free carbene which was generated in situ by adding the phosphine-imidazolium salt, 2.5, to the base, $\mathrm{KN}\left(\mathrm{SiMe}_{3}\right)_{2}$. Addition of one or two equivalents of the free carbene to the palladium metal precursor, $\left[\mathrm{PdCl}_{2}(\mathrm{COD})\right]$, in THF followed by workup with $\mathrm{CH}_{3} \mathrm{CN}$, gave the bis-(phosphine-NHC) $\mathrm{Pd}(\mathrm{II})$ complex as a pale brown solid, Scheme 3.6.

Scheme 3.6: Formation of Pd-complex, 3.5, via free carbene

The product was characterised by ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C},{ }^{31} \mathrm{P}-\mathrm{NMR}$, and high resolution mass spectroscopies, crystals suitable for a crystallographic determination could not be obtained. The ${ }^{1} \mathrm{H}$-NMR spectrum of $\mathbf{3 . 5}$ shows the coordination of the carbene to the palladium metal centre by the absence of the distinctive protonated carbene proton, ${ }_{\mathrm{im}} \mathrm{C}_{1}-\mathrm{H}$, Figure 3.7, which appears at 9.62 ppm in the corresponding phosphine-imidazolium salt. The aliphatic region of
the spectrum is more clearly observed in $\mathrm{CD}_{3} \mathrm{CN}$, Figure 3.7(A). However the aromatic region is more clearly displayed in $\mathrm{CDCl}_{3}$ solvent, Figure 3.7 (B). A singlet resonance attributable to the palladium coordinated phosphorus atom was observed in the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$-NMR spectrum at 37.5 ppm in $\mathrm{CD}_{3} \mathrm{CN}$, shifted downfield from the corresponding peak of the imidazolium precursor which appears at -6.8 ppm (in $\mathrm{CDCl}_{3}$ ), Figure 3.8. The disappearance of the latter phosphorus peak in the spectra indicates complete coordination of the ligand to the palladium metal atom in a chelating manner. A mass peak at 327.1 amu is observed in the mass spectrum. This corresponds to half molecular mass since the palladium complex is doubly charged and validates the formulation; other peaks in the mass spectrum are also consistent with the formulation.

Figure 3.7: ${ }^{1} \mathrm{H}$-NMR spectra of Pd-complex, 3.5

Figure 3.8: ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$-NMR spectrum of Pd -complex, in $\mathrm{CD}_{3} \mathrm{CN}, \mathbf{3 . 5}$

## B. Via Transmetallation:

The synthesis of phosphorus-NHC palladium(II) complex 3.5 was achieved via transmetallation from the corresponding silver(I) complex 3.2. Half a molar quantity of complex 3.2 and the palladium precursor, $\left[\mathrm{PdCl}_{2}(\mathrm{COD})\right]$ or $\left[\mathrm{Pd}(\mathrm{OAc})_{2]}\right.$, was stirred together in dichloromethane at room temperature until precipitation of silver iodide ceased (as an indication that the transmetallation reaction had occurred and was complete). The resulting pale brown bis-(phosphine-NHC) $\operatorname{Pd}(\mathrm{II})$ complex was isolated by precipitation from dichloromethane upon addition of diethyl ether, Scheme 3.7.

The product was characterised by ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C},{ }^{31} \mathrm{P}-\mathrm{NMR}$ and high resolution mass spectroscopies, which confirmed that the same product (complex 3.5) had been formed as obtained from the free carbene. Attempts to obtain crystals suitable for X-ray crystallography were unsuccessful.

Scheme 3.7: Formation of Pd-complex, 3.5, via transmetallation

### 3.3.3: Pt Complex

In trials for platinum complexation with phosphine-imidazolium salts, $\mathbf{2 . 5}$ and $\mathbf{2 . 6}$, via free carbene and by transmetallation methods, two complexes were obtained, the bis-(phosphine-NHC) Pt(II) complex, 3.6, and the mono-( phosphine-NHC) Pt(II) complex, 3.7.

### 3.3.3.1: Bis-(phosphine-NHC) Pt complex, 3.6

## Via Free Carbene:

Following the same synthetic procedure outlined above for $\mathrm{Ni}(\mathrm{II})$ and $\mathrm{Pd}(\mathrm{II})$ complexes, the bis-chelate bis-(phosphine-NHC) platinum(II) complex, 3.6, was prepared
from the free carbene. Solution of the free carbene in THF was reacted with one equivalent of the platinum precursor, $\left[\mathrm{PtCl}_{2}(\mathrm{COD})\right]$, to give an orange solution from which a yellow solid was isolated and identified as the bis-(phosphine-NHC) $\operatorname{Pt}(\mathrm{II})$ complex, in $40 \%$ yield, Scheme 3.8. Crystals of $\mathbf{3 . 6}$ suitable for X-ray crystallography were obtained from saturated MeOH or DCM solutions upon cooling (at $5^{\circ} \mathrm{C}$ ).

Scheme 3.8: Formation of Pt-complex, 3.6, via free carbene

The product was fully characterised by ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C},{ }^{31} \mathrm{P}-\mathrm{NMR}$ and high resolution mass spectroscopies as well as by an X-ray crystallographic determination. The ${ }^{1} \mathrm{H}$-NMR spectrum of 3.6, in $\mathrm{CD}_{3} \mathrm{OD}$, shows the coordination of the carbene to the platinum by the absence of the distinctive protonated carbene proton, ${ }_{i m} \mathrm{C}_{1}-\mathrm{H}$, Figure 3.9.

Figure 3.9: ${ }^{1} \mathrm{H}-\mathrm{NMR}$ and ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}-\mathrm{NMR}$ spectra of Pt-complex, in $\mathrm{CD}_{3} \mathrm{OD}$, 3.6

A characteristic singlet was observed in the ${ }^{31} \mathrm{P}-\mathrm{NMR}$ spectrum, Figure 3.9, which indicates that only one product was formed from this reaction. In $\mathrm{CD}_{3} \mathrm{OD}$, a chemical shift value for the coordinated phosphine to the platinum metal in the bis-(phosphine-NHC) $\mathrm{Pt}(\mathrm{II})$ complex is observed at 30 ppm . This peak has two platinum satellites ( ${ }^{1} J_{\mathrm{Pt}-\mathrm{P}}=2790 \mathrm{~Hz}$ ). The presence of Pt satellites indicates that the phosphine is not labile under the conditions (on the NMR timescale). The phosphine resonance is shifted downfield compared to the corresponding free ligand to a similar extent as in the Pd analogue. Again, the spectrum showed the absence of free phosphine indicating complete coordination of the ligand to the metal centre and consistent with a chelating bonding mode. A peak in the mass spectrum with a molecular mass of 371.7 amu corresponds to the half molecular ion and since the platinum complex is doubly charged, validates the formulation; other mass peaks are also consistent. The crystal structure and labelling Scheme for 3.6, in $\mathrm{CD}_{3} \mathrm{OD}$, is shown in Figure 3.10. Complex 3.6 exhibits a square planar geometry, which is distorted around the platinum where each chelating arm of the ligand occupies trans-positions to the corresponding one, where

Figure 3.10: Molecular structure of Pt-complex (Oretp projection of compound 3.6, in $\mathrm{CD}_{3} \mathrm{OD}, 40 \%$ probability ellipsoids, Hydrogen atoms are omitted for clarity) (Appendix: Data Set 4)
carbene is trans to carbene and phosphorus is trans to phosphorus. This distortion is confirmed by the significant deviation of the C-Pt-C angle ( $170.6^{\circ}$ ) and the P-Pt-P angle $\left(157.9^{\circ}\right)$ from the ideal $180^{\circ}$. The C-Pt-C angle is closer to linearity than the $\mathrm{P}-\mathrm{Ni}-\mathrm{P}$ angle resembling that of Ni-complex 3.4. This six-membered ring formed by the chelating phosphine and carbene donors to the metal centre is twisted.

The Pt-C(1), Pt-C(17), Pt-P(1) and Pt-P(2) bond lengths in complex 3.6 are 2.033(5) $\AA, 2.026(4) \AA, 2.3187(12) \AA$, and $2.3137(12) \AA$ respectively. These are close to reported values in related complexes; selected values are listed in table 3.3. Most notably, due to the metal size, Pt-C and Pt-P bond lengths in platinum complex, 3.6 are longer than the corresponding nickel complex, 3.4. The Pt-C bonds are shorter than the Pt-P bonds which is consistent with the relative magnitudes of the covalent radii of the donor atoms. The angles within the imidazole ring, $\mathrm{N}(1)-\mathrm{C}(1)-\mathrm{N}(2), 106.1(4)^{\circ}$, and $\mathrm{N}(3)-\mathrm{C}(17)-\mathrm{N}(4), 104.2(4)^{\circ}$, are within the known range $101^{\circ}-106^{\circ} .^{14}$ Selected bond lengths and angles are presented in Table 3.3.

Table 3.3: Selected bond lengths $(\AA)$ and angles $\left({ }^{\circ}\right)$ for phosphorus-NHC Pt-complex, 3.6.

| Bond Lengths( $\AA$ ) |  |  | Bond Angles ( ${ }^{\circ}$ ) |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- |
|  |  |  |  |  |  |
| $\mathrm{P}(1)-\mathrm{Pt}(1)$ | $2.3187(12)$ | $\mathrm{C}(6)-\mathrm{P}(1)$ | $1.841(5)$ | $\mathrm{C}(1)-\mathrm{Pt}(1)-\mathrm{P}(1)$ | $80.16(13)$ |
| $\mathrm{P}(2)-\mathrm{Pt}(1)$ | $2.3137(12)$ | $\mathrm{C}(11)-\mathrm{P}(1)$ | $1.833(5)$ | $\mathrm{C}(17)-\mathrm{Pt}(1)-\mathrm{P}(2)$ | $84.82(13)$ |
| $\mathrm{C}(1)-\mathrm{Pt}(1)$ | $2.033(5)$ | $\mathrm{C}(14)-\mathrm{P}(1)$ | $1.852(5)$ | $\mathrm{C}(1)-\mathrm{Pt}(1)-\mathrm{P}(2)$ | $97.65(13)$ |
| $\mathrm{C}(17)-\mathrm{Pt}(1)$ | $2.026(4)$ | $\mathrm{C}(26)-\mathrm{P}(2)$ | $1.842(5)$ | $\mathrm{C}(17)-\mathrm{Pt}(1)-\mathrm{P}(1)$ | $100.91(14)$ |
| $\mathrm{C}(1)-\mathrm{N}(1)$ | $1.341(6)$ | $\mathrm{C}(27)-\mathrm{P}(2)$ | $1.840(5)$ | $\mathrm{C}(1)-\mathrm{Pt}(1)-\mathrm{C}(17)$ | $170.67(19)$ |
| $\mathrm{C}(1)-\mathrm{N}(2)$ | $1.352(6)$ | $\mathrm{C}(30)-\mathrm{P}(2)$ | $1.844(5)$ | $\mathrm{P}(1)-\mathrm{Pt}(1)-\mathrm{P}(2)$ | $157.96(4)$ |
| $\mathrm{C}(17)-\mathrm{N}(3)$ | $1.367(6)$ |  |  | $\mathrm{N}(1)-\mathrm{C}(1)-\mathrm{N}(2)$ | $106.1(4)$ |
| $\mathrm{C}(17)-\mathrm{N}(4)$ | $1.349(6)$ |  |  | $\mathrm{N}(3)-\mathrm{C}(17)-\mathrm{N}(4)$ | $104.2(4)$ |

Angles and bonds, Table 3.4, of complex $\mathbf{3 . 6}$ show close agreement with those of related structures of distorted square planar Pt-P-NHC complexes, such as the bis-trimethyl phosphine bis-carbene reported by Yong-Joo, ${ }^{16}$ Figure 3.11, and the bis-triethylphosphine chelating bis-carbene reported by Fryzuk ${ }^{11}$ and others reported by Rourke, ${ }^{17}$ Marinetti ${ }^{18,19}$ and Hahn. ${ }^{20}$ Metrical values are within normal ranges.

### 3.3.3.2: Mono-(phosphine-NHC) $\operatorname{Pt}($ II) complex, 3.7

The mono-(phosphine-NHC) $\operatorname{Pt}(\mathrm{II})$ complex, 3.7, could be prepared either directly from the free carbene, or via transmetallation with the Ag-carbene complex.

## A. Via Free Carbene:

Following the same synthetic procedure described above, the mono-(phosphine-NHC) platinum(II) complex, 3.7 was obtained from the stoichiometric reaction of the Pt (II) precursor, $\left[\mathrm{PtCl}_{2}(\mathrm{COD})\right]$, with the phosphine-carbene formed from the imidazolium salt, 2.6, by action of a base; the product mono-(phosphine-NHC) $\mathrm{Pt}(\mathrm{II})$ complex was isolated as a pale brown solid, Scheme 3.9.

Scheme 3.9: Formation of Pt-complex, 3.7, via free carbene

## B. Via Transmetallation:

The synthesis of the phosphine-NHC pllatinum(II) complex, 3.7, was also achieved via transmetallation from the corresponding $\mathrm{Ag}(\mathrm{I})$ complex 3.2 when half a molar quantity of complex 3.2 was reacted with the $\mathrm{Pt}(\mathrm{II})$ precursor, $\left[\mathrm{PtCl}_{2}(\mathrm{COD})\right]$. The reaction was deemed to be complete when no more silver chloride precipitated from the reaction mixture. Again, the $\mathrm{Pt}(\mathrm{II})$ product complex was isolated as a pale brown solid, Scheme 3.10; crystals suitable for X-ray crystallography could not be obtained.

The product, $\mathrm{Pt}($ II $)$ complex 3.7, was characterised by ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C},{ }^{31} \mathrm{P}-\mathrm{NMR}$ and high resolution mass spectroscopies. The ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum of $\mathbf{3 . 7}$, in $\mathrm{CDCl}_{3}$, gave broad peaks in the aliphatic region but clearly shows the coordination of the carbene to the platinum by the absence of the distinctive protonated carbene proton, $\mathrm{im}_{\mathrm{im}}-\mathrm{H}$, Figure 3.11.

Scheme 3.10: Formation of Pt-complex, 3.7, via transmetallation

A characteristic singlet was observed in the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$-NMR spectrum at 16 ppm , in $\mathrm{CDCl}_{3}$, Figure 3.11, indicating that only one product was formed from this reaction and that the ligand chelates the metal. Two platinum satellites are also observed as would be expected
$\left({ }^{1} J_{\mathrm{Pt}-\mathrm{P}}=4449 \mathrm{~Hz}\right)$. The Pt-P coupling in the bis(P-NHC)Pt complex, 3.6, $(2790 \mathrm{~Hz})$ is substantially smaller than the coupling observed in the mono (P-NHC)Pt complex, 3.7, (4449 $\mathrm{Hz})$; a difference of about 1660 Hz . The geometrical distribution of P cis or trans to halide in mixed ligand complexes has previously been inferred from the magnitude of $J_{\text {P-Pt }}$ coupling constants. It is known ${ }^{21,22}$ that typical $J_{\text {P-Pt }}$ values lie in a range around 2500 Hz and less for P cis to a halide or around 3500 Hz and above for P trans to a halide. These observations have been validated in a number of complexes reported by Rourke, ${ }^{17}$ Marinetti, ${ }^{18,19}{ }^{19}$ Huynh $^{23}$ and Hahn. ${ }^{24}$ For complex 3.7, the coordinated P atom is trans to chloride which go in parallel with the above mentioned observation. The bis-chelate complex, 3.6, has a lower ${ }^{1} J_{\mathrm{Pt}-\mathrm{P}}$ value. The trans phosphine arrangement weakens (or reduces the sigma character) the Pt-P bond due to the larger trans influence of P donors over chloride.

Figure 3.11: ${ }^{1} \mathrm{H}-\mathrm{NMR}$ and ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$-NMR spectra of Pt-complex 3.7, in $\mathrm{CDCl}_{3}$.

## 3.4: Results and discussion of NHC-phosphine complexes of Mn

## Via Transmetallation:

The synthesis of phosphorus-NHC manganese(I) complex 3.8 was achieved via transmetallation from the corresponding $\mathrm{Ag}(\mathrm{I})$ complex 3.2. Reaction of half a molar quantity of the $\mathrm{Ag}(\mathrm{I})$ complex, 3.2, with the $\mathrm{Mn}(\mathrm{I})$ precursor, $\mathrm{Mn}(\mathrm{CO})_{5} \mathrm{Br}$ gives a yellow solid identified as the mono-(phosphine-NHC)Mn(I) bromotricarbonyl complex, 3.8, Scheme 3.11.

Scheme 3.11: Synthesis of Mn-complex, 3.8, via transmetallation

The product was fully characterised by ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C},{ }^{31} \mathrm{P}-\mathrm{NMR}$ and high resolution mass spectroscopies, and by an X-ray crystallographic determination. The ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum of 3.8, in $\mathrm{CDCl}_{3}$, shows the coordination of the carbene to the manganese metal centre by the absence of ${ }_{\mathrm{im}} \mathrm{C}_{2}-\mathrm{H}$, Figure 3.12. The spectrum shows broad peaks in the aliphatic region presumably due to quadrupolar broadening from the Mn nucleus, which is commonly observed. A singlet was observed in the ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$-NMR spectrum, in $\mathrm{CDCl}_{3}$, at 48.4 ppm due to the Mn-coordinated phosphine exhibiting a substantial coordination chemical shift of (ca.) 55 ppm , Figure 3.12. The molecular ion was observed in the mass spectrum.

Figure 3.12: ${ }^{1} \mathrm{H}-\mathrm{NMR}$ and ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$-NMR spectra of Mn-complex, 3.8, in $\mathrm{CDCl}_{3}$

Crystals suitable for a single crystal X-ray crystallographic determination were obtained by cooling a saturated solution of $\mathbf{3 . 8}$ (in MeOH at $5^{\circ} \mathrm{C}$ ). The crystal structure and
labelling Scheme for $\mathbf{3 . 8}$ is shown in Figure 3.13. The structure of complex $\mathbf{3 . 8}$ is constituted of a single ligand unit bound to a manganese bromo-tricarbonyl fragment in a distorted octahedral geometry around the manganese metal centre. The bromine occupies a cis-position to both chelating arms of the carbene and the phosphine atoms; thus the P and C donors both appear to prefer coordination trans to the higher trans effect (carbonyls) than the low trans effect (bromine). Distortions from idealised octahedral parameters are confirmed by the deviation of the $\mathrm{C}_{1}-\mathrm{Mn}-\mathrm{C}_{18}\left(178.05^{\circ}\right)$ and the $\mathrm{C}_{17}-\mathrm{Mn}-\mathrm{P}$ angles (171.8 $)$ from the ideal $180^{\circ}$. These angles are similar to the data reported by Edwards and Hahn et al. for similar chelating carbene-phosphine ligands. ${ }^{25}$ Like the nickel complex, the $\mathrm{C}_{1}-\mathrm{Ni}-\mathrm{C}_{18}$ angle is closer to linearity than is the $\mathrm{P}_{1}-\mathrm{Ni}-\mathrm{P}_{2}$ angle.

Figure 3.13: Molecular structure of Mn-complex (ORTEP projection of compound 3.8, in $\mathrm{CD}_{3} \mathrm{OD}, 40 \%$ probability ellipsoids, hydrogen atoms are omitted for clarity, Appendix: Data Set 5)

The six-membered ring formed by the two chelating donors to the metal centre is twisted and the ligand bite angle (for the chelating unit) is $82.5^{\circ}$. This bite angle is close to that of related manganese(I) phosphine-NHC complexes (e.g. $81.6^{\circ}$ ). ${ }^{22}$ The $\mathrm{Mn}-\mathrm{C}(1)$ bond
length in $\mathbf{3 . 8}$ is in the normal range, $2.047(3) \AA$, and again is similar to values in related complexes although the $\mathrm{Mn}-\mathrm{P}(1)$ bond length, $2.3171(8) \AA$, is longer than in previously reported analogues. ${ }^{25}$ Angles within the imidazole ring, $\mathrm{N}(1)-\mathrm{C}(1)-\mathrm{N}(2), 103.6(2)^{\circ}$ are within the expected range $101^{\circ}-106^{\circ} .{ }^{14}$ Selected bond lengths and angles are collected in Table 3.5.

Table 3.5: Some selected bond lengths and angles for P-NHC manganese complex, 3.8.

| Bond Lengths ( $\AA$ ) |  |  | Bond Angles ( ${ }^{\circ}$ ) |  |
| :--- | :--- | :--- | :--- | :--- |
|  |  |  |  |  |
| $\mathrm{P}(1)-\mathrm{Mn}(1)$ | $2.317(1)$ | $\mathrm{C}(6)-\mathrm{P}(1)$ | $1.835(3)$ | $\mathrm{C}(1)-\mathrm{Mn}(1)-\mathrm{P}(1)$ |
|  | $82.5(0)$ |  |  |  |
| $\mathrm{Br}(1)-\mathrm{Mn}(1)$ | $2.593(7)$ | $\mathrm{C}(11)-\mathrm{P}(1)$ | $1.861(3)$ | $\mathrm{C}(1)-\mathrm{Mn}(1)-\mathrm{Br}(2)$ |
| $96.3(8)$ |  |  |  |  |
| $\mathrm{C}(1)-\mathrm{Mn}(1)$ | $2.047(3)$ | $\mathrm{C}(14)-\mathrm{P}(1)$ | $1.856(3)$ | $\mathrm{C}(1)-\mathrm{Mn}(1)-\mathrm{C}(17)$ |
|  | $89.6(9)$ |  |  |  |
| $\mathrm{C}(17)-\mathrm{Mn}(1)$ | $1.824(3)$ |  | $\mathrm{C}(1)-\mathrm{Mn}(1)-\mathrm{C}(18)$ | $178.0(5)$ |
| $\mathrm{C}(1)-\mathrm{N}(1)$ | $1.359(4)$ |  | $\mathrm{C}(1)-\mathrm{Mn}(1)-\mathrm{C}(19)$ | $91.2(9)$ |
| $\mathrm{C}(1)-\mathrm{N}(2)$ | $1.370(4)$ |  | $\mathrm{P}(1)-\mathrm{Mn}(1)-\mathrm{Br}(1)$ | $88.0(4)$ |
| $\mathrm{C}(18)-\mathrm{Mn}(1)$ | $1.815(3)$ |  | $\mathrm{N}(1)-\mathrm{C}(1)-\mathrm{N}(2)$ | $103.6(2)$ |
| $\mathrm{C}(19)-\mathrm{Mn}(1)$ | $1.823(4)$ |  |  |  |

In Mn-complex, 3.8, bond length of $\mathrm{C}_{2}-\mathrm{C}_{3}$ and $\mathrm{N}_{1}-\mathrm{C}_{4}$ are $1.337(5)$ and $1.463(4)$ which nearly match the bond length of the same position in the free ligand $\mathbf{2 . 5}, 1.334(8)$ and $1.460(7)$ respectively. However, the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum show multiplet peaks of these two imidazolinium protons, $\mathrm{C}_{2}-\mathrm{H}$ and $\mathrm{C}_{3}-\mathrm{H}$, due to the paramagnetic behaviour of $\mathrm{Mn} . \mathrm{C}_{1}-\mathrm{N}_{1}$ $(1.359(4) \AA)$ and $\mathrm{C}_{1}-\mathrm{N}_{2}(1.370(4) \AA)$ get longer than their analogous bonds in the ligand $\mathbf{2 . 5}$, (1.313(7) and 1.34(7) $\AA$ ), Table 3.6. It may due to the $\sigma$ - donation from the carbene to the metal and negligible back bonding from the metal to the vacant carbene orbitals. The MnC(carbonyl) bond lengths are 1.815 (3), 1.823(4) and $1.824(3)$ which are in the average range. However, the observed shortest bond length of the carbonyl (CO) is the one $\left(\mathrm{C}_{19}-\mathrm{O}_{3}\right)$ being trans to bromine due to the oxygen back bonding to the carbon, Table 3.6.

Table 3.6: Comparison of selected bond lengths $(\AA)$ for phosphorus-NHC manganese complex, 3.8

## 3.5: Results and discussion of NHC-phosphine complexes of Ir

## Via Free Carbene:

The same work-up methodology as previously reported for complexes synthesised by the formation of free carbene was followed. When phosphine-imidazolium salt 2.5 was reacted with one equivalent of base of $\mathrm{KN}\left(\mathrm{SiMe}_{3}\right)_{2}$ in THF at $-78{ }^{\circ} \mathrm{C}$, the imidazolium salt was rapidly deprotonated by the base to form the carbene, Scheme 3.12. The deprotonation was complete in about 15 minutes and the solution was added via a cannula into a second Schlenk containing one equivalent of the $\operatorname{Ir}(\mathrm{I})$ precursor, $[\operatorname{IrCl}(\mathrm{COD})]_{2}$. The mixture was left stirring at this temperature for another ten minutes and then allowed to reach ambient temperature and stirred for 18 hours. After the reaction, THF was evaporated, and DCM was added to extract the crude product. DCM was removed under vacuum and the addition of
$\mathrm{Et}_{2} \mathrm{O}$ led to the isolation of a red/brown solid, as mono-(phosphine-NHC) $\mathrm{Ir}(\mathrm{I})$ complex, 3.9, Scheme 3.12.

Scheme 3.12: Attempted synthesis of Ir-complex, 3.9, via free carbene

Although there was no ${ }_{\mathrm{im}} \mathrm{C}_{2}-\mathrm{H}$ proton in the ${ }^{1} \mathrm{H}-\mathrm{NMR}$, Figure 3.14, broad peaks were present in the aliphatic region of the spectra and made it difficult to interpret clearly. Attempts to isolate complex 3.9 as a pure compound via recrystalization failed. The ${ }^{31} \mathrm{P}$-NMR spectrum, in $\mathrm{CDCl}_{3}$, showed no sign of the free phosphine, but a single peak at 0.4 ppm indicated the formation of a new $\operatorname{Ir}(\mathrm{I})$ complex, Figure 3.14. The mass spectrometry data showed one highest fragment peak at 573.2 amu corresponding to the molecular mass of the mono-(phosphine-NHC) iridium(I) complex minus one proton, $[\mathrm{M}-\mathrm{H}]$.

Figure 3.14: ${ }^{1} \mathrm{H}-\mathrm{NMR}$ and ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$-NMR spectra of Ir-complex, 3.9, in $\mathrm{CDCl}_{3}$

## 3.6: Conclusion:

New manganese, iridium, group 10, and group 11 metal phosphine-NHC complexes have been prepared and characterised by spectroscopic means, including ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ and ${ }^{31} \mathrm{P}$ NMR and mass spectrometry and in some cases by elemental analysis. These complexes are synthesised via known methods such as formation of free carbene or by transmetallation. Complexes of Au (3.1), Cu (3.3), Ni (3.4), Pd (3.5), Pt-bis (3.6), Pt-mono (3.7) and Ir (3.9) metals were solely synthesised via the formation of free carbene, while complexes of Pd (3.5) and Pt-mono (3.7) metals were synthesised by both free carbene and by transmetallation from the corresponding silver(I) complex 3.2. The Mn complex (3.8) was prepared by transmetallation. Solid state structures of complexes 3.4, 3.6 and $\mathbf{3 . 8}$ have been obtained by crystallographic measurements, showing some information and properties in depth of these chelating ligands. Some metal complexes have mono chelating unit and others are bis chelating unit, where each unit is a bi-dentate stems of carbene and phosphine groups.

The complexes formed clearly demonstrate that this carbene-phosphine ligand forms robust chelate complexes. In examples where two carbene-phosphine ligands coordinate the same central metal ion, a trans orientation of phosphines ( P trans to P ) and carbenes is observed.

## 3.7: Experimental

### 3.7.1: General Comments and Materials:

Acetonitrile ( MeCN ) was dried over $3 \AA$ molecular sieves and calcium hydride. Petrol was initially dried over sodium wire and distilled under nitrogen and over sodium wire. NMR deuterated solvents ( MeOD and $\mathrm{CD}_{3} \mathrm{CN}$ ) were purchased from Aldrich or Across Fisher. $\mathrm{KN}\left(\mathrm{SiMe}_{3}\right)_{2}$ was purchased from its commercial supplier and kept inside a glove box and used as it's. Metal precursors such as $\mathrm{NiCl}_{2} \cdot \mathrm{DME}^{26,27}, \mathrm{PdCl}_{2}(\mathrm{COD}), \mathrm{PtCl}_{2}(\mathrm{COD}),{ }^{28,29}$ $\left[\mathrm{Cu}(\mathrm{MeCN})_{4}\right] \mathrm{BF}_{4},{ }^{30}$ and $[\mathrm{IrCl}(\mathrm{COD})]_{2}{ }^{31,32}$ were prepared by known procedures. However, the metal precursors of $\mathrm{MnCO}_{5} \mathrm{Br}, \mathrm{K}_{2} \mathrm{PtCl}_{4}, \mathrm{Pd}(\mathrm{OAc})_{2}, \mathrm{Ag}_{2} \mathrm{O}$ and $\left(\mathrm{Me}_{2} \mathrm{~S}\right) \mathrm{AuCl}$ were purchased from commercial suppliers.

The other relevant general comments and materials are detailed in the experimental section in chapter 2, (2.4.1).

### 3.7.2 Preparation of Complexes

## Synthesis of mono-(phosphine-carbene) Au(I) complex (3.1):

## (Via Free Carbene):

To a mixture of phosphine-imidazolium salt (2.5) ( $0.10 \mathrm{~g}, 0.248 \mathrm{mmol}$ ) ( 1 equiv.) and $\mathrm{KN}\left(\mathrm{SiMe}_{3}\right)_{2}(0.054 \mathrm{~g}, 0.273 \mathrm{mmol})$ ( 1.1 equiv.) was added pre-cooled THF ( 50 ml at $-78{ }^{\circ} \mathrm{C}$ ). The resulting mixture was stirred at this temperature for 10 min ., then added via a cannula to a pre-cooled gold precursor $\left(\mathrm{Me}_{2} \mathrm{~S}\right) \mathrm{AuCl}(0.073 \mathrm{~g}, 0.248 \mathrm{mmol})$ ( 1 equiv.) in THF ( 30 ml ). The mixture was left stirring at this temperature for another 10 min . and then allowed to reach ambient temperature, and stirred for 18 h . No precipitate was formed. The solvent was removed under vacuum to give a brown solid which was dissolved in DCM and $\mathrm{Et}_{2} \mathrm{O}$ was
added ( $3 \times 30 \mathrm{ml}$ ) to precipitate the light brown product complex in $20 \%$ yield. ${ }^{1} \mathrm{H}$ NMR ( 500 $\left.\mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right): 7.64\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{im}_{2 / 3}\right), 7.52\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{H}_{\mathrm{Ar}}\right), 7.47\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{im}_{2 / 3}\right), 7.45(\mathrm{~m}, 2 \mathrm{H}$, $\mathrm{H}_{\text {Ar }}$ ), $4.0(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Me}), 1.28\left(\mathrm{~m}, 1 \mathrm{H}, \mathrm{CH}_{11 / 14}\right), 1.25\left(\mathrm{~m}, 1 \mathrm{H}, \mathrm{CH}_{11 / 14}\right), 0.85\left(\mathrm{~m}, 12 \mathrm{H}, \mathrm{CH}_{3}\right) .{ }^{31} \mathrm{P}$ NMR ( $202.5 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): 47.8 ppm . MS (ES+): M/z (\%); 745.2831 [M]

## Synthesis of bis-(phosphine-carbene) $\mathbf{A g}(\mathrm{I})$ complex (3.2):

To a mixture of phosphine-imidazolium salt (2.5) ( $0.1 \mathrm{~g}, 0.248 \mathrm{mmol}$ ) (2 equiv.) and $\mathrm{Ag}_{2} \mathrm{O}(0.043,0.186 \mathrm{mmol})$ (1 equiv.) dried and degassed $4 \AA$ molecular sieves was added DCM ( 50 ml at ambient temperature). The resulting mixture was stirred in the dark at this temperature for 18 h . The solvent was filtered three times into another Schlenk and the precipitate was washed once with DCM. The combined solvents were removed under vacuum to give a light grey solid. The solid was washed twice with $\mathrm{Et}_{2} \mathrm{O}(2 \times 20 \mathrm{ml})$ and then extracted into DCM ( $2 \times 20 \mathrm{ml}$ ), filtered and dried in vacuo; yield is ( $80 \%$ ). ${ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right.$, ס): $7.50\left(\mathrm{~m}, 6 \mathrm{H}, \mathrm{H}_{\mathrm{Ar}}\right), 7.20\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{H}_{\mathrm{Ar}}\right), 7.10\left(\mathrm{~s}, 2 \mathrm{H},{ }_{\mathrm{im}} \mathrm{H}_{2 / 3}\right), 6.95\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{im}_{2 / 3}\right), 3.77(\mathrm{~s}, 6 \mathrm{H}$, Me ), 2.25 ( $\mathrm{m}, 4 \mathrm{H}, \mathrm{CH}_{11,14 / 27,30}$ ), 1.10 (dd, J=6.9, 17.8, 12H, $\mathrm{CH}_{3}$ ), 0.95 (dd, J=6.9, 14.5, 12H, $\mathrm{CH}_{3}$ ) ppm. ${ }^{13} \mathrm{C}$ NMR ( $125.75 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): 181.4 ( $\mathrm{s}, \mathrm{C}$ ), 145.3 (d, J=13.75, C), 133.5 (s, CH), 131.5 ( $\mathrm{s}, \mathrm{CH}$ ), 129.4 (d, J= 32.5,CH), 128.7 (s, CH), 123.8 (d, J=35, CH), 122.8 ( $\mathrm{s}, \mathrm{CH}$ ), 116.7 (d, J=20, CH), $39.9\left(\mathrm{~s}, \mathrm{CH}_{3}\right), 24.9(\mathrm{~s}, \mathrm{CH}), 19.9\left(\mathrm{~d}, \mathrm{~J}=13.75 \mathrm{CH}_{3}\right.$ ), 19.1 ( $\mathrm{d}, \mathrm{J}=31.25$, $\mathrm{CH}_{3}$ ) ppm. ${ }^{31} \mathrm{P}$ NMR ( $202.5 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): $5.43 \mathrm{ppm} . \mathrm{MS}\left(\mathrm{ES}+\right.$ ): M/z; $655.2[\mathrm{M}-\mathrm{H}]^{+}$, $671.2[\mathrm{M}+\mathrm{Me}]^{+} . \mathrm{MS}(\mathrm{ES}-): \mathrm{M} / \mathrm{z} ; 360.6[\mathrm{M}-\mathrm{H}]$.

## Synthesis of bis-(phosphine-carbene) $\mathbf{C u}$ (I) complex (3.3):

(Via Free Carbene):
To a mixture of phosphine-imidazolium salt ( $\mathbf{2 . 5}$ ) $(0.15 \mathrm{~g}, 0.373 \mathrm{mmol})$ ( 1 equiv.) and $\mathrm{KN}\left(\mathrm{SiMe}_{3}\right)_{2}(0.082 \mathrm{~g}, 0.41 \mathrm{mmol})$ ( 1.1 equiv.) was added pre-cooled THF ( 50 ml at $-78{ }^{\circ} \mathrm{C}$ ). The resulting mixture was stirred at this temperature for 10 min ., then added via a cannula to a pre-cooled copper precursor $\left[\mathrm{Cu}(\mathrm{MeCN})_{4}\right] \mathrm{BF}_{4}(0.058 \mathrm{~g}, 0.186 \mathrm{mmol})$ ( 0.5 equiv.) in THF $(30 \mathrm{ml})$. The mixture was left stirring at this temperature for another 10 min . and then allowed to reach r.t. and stirred for 18 h . The precipitated solid was filtered and washed with THF $(2 \times 20 \mathrm{ml})$ and then $\mathrm{Et}_{2} \mathrm{O}(2 \times 20 \mathrm{ml})$ and then extracted into DCM ( $2 \times 20 \mathrm{ml}$ ). The DCM was removed under vacuum to give an off-white solid.

## (Via transmetallation):

To a mixture of $\left[\mathrm{Cu}(\mathrm{MeCN})_{4}\right] \mathrm{BF}_{4}(0.015 \mathrm{~g}, 0.098 \mathrm{mmol})$ and the silver adduct of the carbene-phosphine complex, 3.2, $(0.05 \mathrm{~g}, 0.049 \mathrm{mmol})$ was added $\mathrm{DCM}(0 \mathrm{ml})$ and the mixture left to stir at r.t. for 18 h . The solution was filtered. DCM was removed under vacuum and the resulting solid was washed twice with $\mathrm{Et}_{2} \mathrm{O}(20 \times 2)$. The resulting pale brown solid was re-crystallised from $\mathrm{DCM} / \mathrm{E}_{2} \mathrm{O}$ to give the product which was then dried under vacuum. Yield is $(25 \%)$. ${ }^{1} \mathrm{H}$ NMR ( $500 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): $7.47\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{H}_{\mathrm{Ar}}\right), 7.32\left(\mathrm{~m}, 6 \mathrm{H}, \mathrm{H}_{\mathrm{Ar}}\right), 7.24(\mathrm{~s}$, $4 \mathrm{H}, \mathrm{im}_{2,3}$ ), 3.45 (s, $6 \mathrm{H}, \mathrm{Me}$ ), 2.14 (m, 4H, $\mathrm{CH}_{11,14 / 27,30}$ ), 0.87 (br, 12H, $\mathrm{CH}_{3}$ ), 0.60 (br, 6 H , $\mathrm{CH}_{3}$ ), 0.38 (dd, J=17.5, 7.5, 6H, $\mathrm{CH}_{3}$ ) ppm. ${ }^{13} \mathrm{C}$ NMR ( $125.75 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): $189.1(\mathrm{~s}, \mathrm{C})$, 144.2 (d, J=10, C), 132.8 ( $\mathrm{s}, \mathrm{CH}$ ), 130.9 ( $\mathrm{s}, \mathrm{CH}$ ), 126.7 ( $\mathrm{s}, \mathrm{CH}$ ), 124.6 ( $\mathrm{d}, \mathrm{J}=3.75, \mathrm{CH}$ ), 123.7 (d, J=7.5, CH), 123.1 ( $\mathrm{s}, \mathrm{CH}$ ), $121.0(\mathrm{~s}, \mathrm{CH}), 38.2\left(\mathrm{~s}, \mathrm{CH}_{3}\right), 22.7(\mathrm{~s}, \mathrm{CH}), 22.2(\mathrm{~s}, \mathrm{CH}), 18.7$ (s, $\mathrm{CH}_{3}$ ), $17.8\left(\mathrm{~s}, \mathrm{CH}_{3}\right), 17.1\left(\mathrm{~s}, \mathrm{CH}_{3}\right) \mathrm{ppm} .{ }^{31} \mathrm{P} \operatorname{NMR}\left(121.7 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right): 3.8 \mathrm{ppm} . \mathrm{MS}$ (ES+): M/z; $611.1[\mathrm{M}-\mathrm{H}]^{+}$. Anal.: Calc. For $\mathrm{C}_{32} \mathrm{H}_{46} \mathrm{~N}_{4} \mathrm{P}_{2} \mathrm{CuBF}_{4}$ : C, 54.98; H, 6.63; N, $8.01 \%$. Found: C, 50.31 ; H, 6.03; N, 7.13\%.

## Synthesis of bis-(phosphine-carbene) Ni(II) complex (3.4):

## (Via Free Carbene)

To a mixture of phosphine-imidazolium salt (2.5) ( $0.10 \mathrm{~g}, 0.25 \mathrm{mmol}$ ) ( 1 equiv.) and $\mathrm{KN}\left(\mathrm{SiMe}_{3}\right)_{2}(0.055 \mathrm{~g}, 0.276 \mathrm{mmol})$ ( 1.1 equiv.) was added pre-cooled THF ( 50 ml at $-78{ }^{\circ} \mathrm{C}$ ). The resulting mixture was stirred at this temperature for 10 min ., then added via a cannula to a pre-cooled nickel precursor $\mathrm{NiCl}_{2}$.DME ( $0.055 \mathrm{~g}, 0.25 \mathrm{mmol}$ ) ( 1 equiv.) in THF ( 30 ml ). The mixture was left stirring at this temperature for another 10 min . and then allowed to reach room temperature, and stirred for 18 h after which time the reaction had ceased and a precipitate formed. The supernatant was decanted and the solid washed twice with THF and extracted into DCM. The solution was left to settle for about 2 h whereupon a yellow precipitate formed. The solid was re-crystallised from EtOH. Yield ( $0.13 \mathrm{~g}, 32 \%$ ). ${ }^{1} \mathrm{H}$ NMR ( $\left.500 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}, \delta\right): 7.75-7.4\left(\mathrm{~m}, 12 \mathrm{H}, \mathrm{H}_{\mathrm{Ar}}\right), 4.20(\mathrm{~s}, 6 \mathrm{H}, \mathrm{Me}), 2.58\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{H}_{11 / 14}\right), 2.34$ ( $\mathrm{m}, 2 \mathrm{H}, \mathrm{H}_{27 / 30}$ ), $0.82\left(\mathrm{dd}, \mathrm{J}=14.2,7.0,3 \mathrm{H}, \mathrm{CH}_{3}\right), 0.55\left(\mathrm{dd}, \mathrm{J}=14.9,7.4,3 \mathrm{H}, \mathrm{CH}_{3}\right), 0.42(\mathrm{~m}$, $18 \mathrm{H}, 6 \mathrm{CH}_{3}$ ) ppm. ${ }^{13} \mathrm{C}$ NMR ( $125.75 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}, \delta$ ): 134.1 (d, J=17.5, CH), 129.2 (d, J=37.5, CH), 123.5 (d, J=47.5, CH), 38.5 ( $\mathrm{s}, \mathrm{CH}$ ), 27.4 (d, J=11.25, CH), 20.3 (d, J=26.25, CH ), $17.0\left(\mathrm{~d}, \mathrm{~J}=7.5, \mathrm{CH}_{3}\right), 16.5\left(\mathrm{~s}, \mathrm{CH}_{3}\right), 13.9\left(\mathrm{~s}, \mathrm{CH}_{3}\right) \mathrm{ppm} .{ }^{31} \mathrm{P}$ NMR (202.5 MHz, $\mathrm{CD}_{3} \mathrm{CN}$, §): $36.9 \mathrm{ppm} . \mathrm{MS}(\mathrm{ES}+): \mathrm{M} / \mathrm{z}(\%) ; 303.13$ (100) [M/2], 734 (67) [M+I] ${ }^{+} 648.3$ (20) $\left[\mathrm{M}+\mathrm{CH}_{3} \mathrm{CN}\right]^{+}$. X-Ray: Single crystals of the nickel complex 3.4 were obtained from a saturated solution in ethanol (EtOH) at $5^{\circ} \mathrm{C}$.

## Synthesis of bis-(phosphine-carbene) $\mathbf{P d}(\mathrm{II})$ complex, using [ $\left.\mathrm{PdCl}_{2} \mathbf{C O D}\right]$ (3.5):

## Method \# 1 (Via Free Carbene):

## Using (2.5):

To a mixture of phosphine-imidazolium salt (2.5) ( $0.1 \mathrm{~g}, 0.248 \mathrm{mmol}$ ) ( 1 equiv.) and $\mathrm{KN}\left(\mathrm{SiMe}_{3}\right)_{2}(0.05 \mathrm{~g}, 0.273 \mathrm{mmol})$ ( 1.1 equiv.) was added pre-cooled THF ( 30 ml at $-78{ }^{\circ} \mathrm{C}$ ). The resulting mixture was stirred at this temperature for 10 min . and then added via a cannula to a stirred solution of pre-cooled palladium precursor $\mathrm{PdCl}_{2}(\mathrm{COD})(0.071 \mathrm{~g}, 0.248 \mathrm{mmol})(1$ equiv.) in THF ( 30 ml at $-78^{\circ} \mathrm{C}$ ). The mixture was left stirring at this temperature for another 10 min and then allowed to reach ambient temperature and stirred for 18 h . THF was removed under vacuum and the solid washed twice with $\mathrm{Et}_{2} \mathrm{O}(2 \times 20 \mathrm{ml})$. The solid was extracted into EtOH , filtered and the solvent removed in vacuo to give the product as a light brown solid.

## Using (2.6):

Reacting the palladium precursor mentioned above with the chloride adduct precursor (2.6) by following the same reaction steps as using the iodide (2.5) gave the same Pdcomplex.

## Method \# 2 (Via Transmetallation):

To a mixture of $\mathrm{PdCl}_{2}(\mathrm{COD}) \quad(0.084 \mathrm{~g}, 0.295 \mathrm{mmol})$ and the silver adduct of the carbene-phosphine complex, 3.2, ( $0.15 \mathrm{~g}, 0.147 \mathrm{mmol}$ ) was added DCM ( 80 ml ) and the mixture left to stir in at ambient temperature for 18 h in the dark. The solution was filtered and DCM was removed under vacuum. The residue was washed twice with $\mathrm{Et}_{2} \mathrm{O}$ (20x2) and the resulting pale brown solid was re-crystallised from $\mathrm{DCM} / \mathrm{Et}_{2} \mathrm{O}$ to give the product which was then dried under vacuum.

## Synthesis of bis-(phosphine-carbene) Pd(II) complex using Pd(OAc) ${ }_{2}$, Via Free Carbene (3.5):

Following the method described above (method \# 1) with the ligand $\mathbf{2 . 6}$ gave the product as a pale brown solid by extraction of the solid reaction residue (following evaporation of solvent in vacuo) into acetonitrile, filtration and evaporation in vacuo. Yield was $(25 \%) .{ }^{1} \mathrm{H}$ NMR ( $\left.400 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right): 7.60\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{H}_{\mathrm{Ar}}\right), 7.52\left(\mathrm{~m}, 4 \mathrm{H}, \mathrm{H}_{\mathrm{Ar}}\right), 7.42(\mathrm{~m}$, $4 \mathrm{H}, \mathrm{H}_{\mathrm{Ar}}$ ), 7.32 ( $\mathrm{s}, 2 \mathrm{H}, \mathrm{H}_{\mathrm{Ar}}$ ), 3.95 ( $\mathrm{s}, 6 \mathrm{H}, \mathrm{Me}$ ); ( $400 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}, \delta$ ): $2.85\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{CH}_{11 / 14}\right.$ ), $2.27\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{CH}_{27 / 30}\right), 0.90\left(\mathrm{dd}, \mathrm{J}=7.7,15.53 \mathrm{~Hz}, 6 \mathrm{H}, \mathrm{CH}_{3}\right), 0.73\left(\mathrm{~m}, 6 \mathrm{H}, \mathrm{CH}_{3}\right), 0.52(\mathrm{~m}, 12 \mathrm{H}$, $\mathrm{CH}_{3}$ ) ppm. ${ }^{13} \mathrm{C}$ NMR ( $125.75 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): 153.8 (d, J=8.75, C), 141.9 (d, J=7.5, C), 132.2 ( $\mathrm{s}, \mathrm{CH}$ ), 130.5 ( $\mathrm{s}, \mathrm{CH}$ ), 127.1 ( $\mathrm{d}, \mathrm{J}=6.25, \mathrm{CH}$ ), 126.5 ( $\mathrm{s}, \mathrm{CH}$ ), 121.6 ( $\mathrm{d}, \mathrm{J}=6.25, \mathrm{CH})$, 120.06 ( $\mathrm{s}, \mathrm{CH}$ ), 117.6 (d, J=42.5, CH), 39.4 ( $\mathrm{s}, \mathrm{Me}$ ), 27.0 ( $\mathrm{s}, \mathrm{CH}$ ), 20.51 ( $\mathrm{s}, \mathrm{CH}$ ), 18.2 (d, $\mathrm{J}=32.5,2 \mathrm{CH}_{3}$ ), $16.81\left(\mathrm{~s}, \mathrm{CH}_{3}\right), 15.0\left(\mathrm{~s}, \mathrm{CH}_{3}\right) \mathrm{ppm} .{ }^{31} \mathrm{P}$ NMR ( $\left.121.7 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}, \delta\right): 37.54$ ppm. MS (ES+): M/z; $696.25\left[\mathrm{M}+\mathrm{CH}_{3} \mathrm{CN}\right], 653.24[\mathrm{M}-2 \mathrm{H}], 327.1[\mathrm{M} / 2]$.

Synthesis of bis-(phosphine-carbene) $\mathbf{P t}(\mathrm{II})$ complex ( 3.6 ):

## (Via Free Carbene):

To a mixture of phosphine-imidazolium iodide ( $\mathbf{2 . 5}$ ) $(0.1 \mathrm{~g}, 0.25 \mathrm{mmol})$ ( 1 equiv.) and $\mathrm{KN}\left(\mathrm{SiMe}_{3}\right)_{2}(0.055 \mathrm{~g}, 0.276 \mathrm{mmol})$ ( 1.1 equiv.) was added pre-cooled THF ( 30 ml at $-78{ }^{\circ} \mathrm{C}$ ). The resulting mixture was stirred at this temperature for 10 min ., and then added via a cannula to a pre-cooled solution of the platinum precursor $\mathrm{PtCl}_{2}(\mathrm{COD})(0.093 \mathrm{~g}, 0.25 \mathrm{mmol})$ ( 1 equiv.) in THF ( 30 ml ). The mixture was left stirring at this temperature for another 10 min . and then was allowed to reach ambient temperature and stirred for 18 h . The solvent was filtered and the light brown precipitate was washed with THF ( $2 \times 20 \mathrm{ml}$ ) and then $\mathrm{Et}_{2} \mathrm{O}(2 \times 20$
ml ) before extraction into DCM. The solid was then dried under vacuum to give the product as a yellow to brown solid. It was recrystallised from MeOH at $5{ }^{\circ} \mathrm{C}$. Yield $(0.08 \mathrm{~g}, 40 \%) .{ }^{1} \mathrm{H}$ NMR ( $\left.400.13 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{OD}, \delta\right): 8.0-7.5\left(\mathrm{~m}, 12 \mathrm{H}, \mathrm{H}_{\mathrm{Ar}}\right), 4.10(\mathrm{~s}, 6 \mathrm{H}, \mathrm{Me}), 2.93(\mathrm{~m}, 2 \mathrm{H}$, $\mathrm{CH}_{11,14}$ ), $2.45\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{CH}_{11,14}\right), 1.68\left(\mathrm{dd}, \mathrm{J}=6.9,14 \mathrm{~Hz}, 6 \mathrm{H}, \mathrm{CH}_{3}\right), 1.58(\mathrm{dd}, \mathrm{J}=7.5,17.5 \mathrm{~Hz}$, $\left.6 \mathrm{H}, \mathrm{CH}_{3}\right), 0.98\left(\mathrm{dd}, \mathrm{J}=7.8,19 \mathrm{~Hz}, 6 \mathrm{H}, \mathrm{CH}_{3}\right), 0.85-0.60\left(\mathrm{~m}, 6 \mathrm{H}, \mathrm{CH}_{3}\right) \mathrm{ppm} .{ }^{13} \mathrm{C}$ NMR (125.75 $\mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): 143.1 (d, J=5, C), 142.3 (d, J=12.5, C), 133.1 ( $\mathrm{s}, \mathrm{CH}$ ), 131.0 (s, CH), 127.6 ( d, J=7.5, CH), 126.6 ( $\mathrm{s}, \mathrm{CH}$ ), 122.6 (d, J=5, CH), 120.3 ( $\mathrm{s}, \mathrm{CH}$ ), 117.8 (d, J=50, CH), 39.7 ( s , $\mathrm{CH}_{3}$ ), $18.0\left(\mathrm{~d}, \mathrm{~J}=13.75, \mathrm{CH}_{3}\right), 17.8\left(\mathrm{~d}, \mathrm{~J}=20, \mathrm{CH}_{3}\right) \mathrm{ppm} .{ }^{31} \mathrm{P}$ NMR ( $121.7 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{OD}, \delta$ ): $29.68\left({ }^{1} J_{\mathrm{Pt}-\mathrm{P}}=2790 \mathrm{~Hz}\right) \mathrm{ppm} . \mathrm{MS}(\mathrm{ES}+): \mathrm{M} / \mathrm{z}(\%) ; 870.1$ (13) $[\mathrm{M}+\mathrm{I}]^{+}, 371.7$ (100) [M/2]. XRay: Single crystals of platinum complex 3.6 were obtained from a saturated solution in methanol $(\mathrm{MeOH})$ at $5^{\circ} \mathrm{C}$.

## Synthesis of mono-(phosphine-carbene) Pt(II) complex (3.7):

Two methods were applied to get the mono-(phospnine-NHC) platinum complex, 3.7.

## Method \# 1 (Via Free Carbene):

To a mixture of phosphine-imidazolium salt ( $\mathbf{2 . 6}$ ) $(0.1 \mathrm{~g}, 0.32 \mathrm{mmol})$ ( 1 equiv.) and $\mathrm{KN}\left(\mathrm{SiMe}_{3}\right)_{2}(0.0635 \mathrm{~g}, 0.354 \mathrm{mmol})$ ( 1.1 equiv.) was added pre-cooled THF ( 30 ml at -78 ${ }^{\circ} \mathrm{C}$ ). The resulting mixture was stirred at this temperature for 10 min ., then added via a cannula to a pre-cooled solution of platinum precursor $\mathrm{PtCl}_{2}(\mathrm{COD})(0.12 \mathrm{~g}, 0.32 \mathrm{mmol})(1$ equiv.) in THF ( 30 ml ). The mixture was left stirring at this temperature for another 10 min . and then was allowed to reach ambient temperature and stirred for 18 h . The reaction ceased and a supernatant layer was formed. This solution was filtered; the solid residue washed once with THF ( 10 ml ) and the combined solution and washings was then dried under vacuum. The residue was washed twice with $\mathrm{Et}_{2} \mathrm{O}(2 \times 20 \mathrm{ml})$ to give the product as a light brown solid.

## Method \# 2 (Via Transmetallation):

To a mixture of $\mathrm{PtCl}_{2}(\mathrm{COD})(0.037 \mathrm{~g}, 0.098 \mathrm{mmol})$ and the silver adduct of the carbene-phosphine complex, 3.2, $(0.05 \mathrm{~g}, 0.049 \mathrm{mmol})$ was added $\mathrm{DCM}(60 \mathrm{ml})$ and the solution stirred at room temperature for 18 h . The solution was then filtered. The volume of DCM was reduced under vacuum and the resulting solid was washed with $\mathrm{Et}_{2} \mathrm{O}$. The resulting pale brown solid was re-crystallised from a minimum volume of DCM to give the product which was then dried under vacuum. ${ }^{1} \mathrm{H}$ NMR $\left(500 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right): 7.7-7.2\left(\mathrm{~m}, 6 \mathrm{H}, \mathrm{H}_{\mathrm{Ar}}\right)$, 4.15 (s, 3H, Me), 2.65 (br, $1 \mathrm{H}, \mathrm{CH}_{11 / 14}$ ), 2.3 (m, 1H, $\mathrm{CH}_{11 / 14}$ ), 1.6-0.70 (br, $12 \mathrm{H}, \mathrm{CH}_{3}$ ) ppm. ${ }^{13} \mathrm{C}$ NMR ( $125.75 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): 143.2 (d, J=5, C), 142.5 (d, J=13.75, C), 133.1 ( $\mathrm{s}, \mathrm{CH}$ ), 131.0 ( $\mathrm{s}, \mathrm{CH}$ ), 128.6 ( s, CH), 127.6 (d, J=7.5, CH), 126.5 ( $\mathrm{s}, \mathrm{CH}$ ), 122.6 (d, J= 5, CH), 120.2 (s, CH), 39.7 ( $\mathrm{s}, \mathrm{Me}$ ), 21.5 (br, CH ), 18.0 (br, $\mathrm{CH}_{3}$ ), 17.7 (br, $\mathrm{CH}_{3}$ ) ppm. ${ }^{31} \mathrm{P}$ NMR (121.7 $\left.\mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right): 15.88\left({ }^{1} \mathrm{~J}_{\mathrm{Pt}-\mathrm{P}}=4449 \mathrm{~Hz}\right) \mathrm{ppm} . \mathrm{MS}(\mathrm{ES}+): \mathrm{M} / \mathrm{z} ; 650.15[\mathrm{M}+\mathrm{COD}], 546.1$ [M$\left.\mathrm{Cl}+\mathrm{CH}_{3} \mathrm{CN}\right], 558.1\left[\mathrm{M}+\mathrm{NH}_{4}{ }^{+}\right], 505.1[\mathrm{M}-\mathrm{Cl}]$.

## Synthesis of mono-(phosphine-carbene) Mn (I) complex (3.8):

## (Via Transmetallation):

To a mixture of $\mathrm{MnCO}_{5} \mathrm{Br}(0.027 \mathrm{~g}, 0.098 \mathrm{mmol})$ (1 equiv) and the silver adduct of the carbene-phosphine complex, 3.2, ( $0.05 \mathrm{~g}, 0.049 \mathrm{mmol}$ ) ( $1 / 2$ equiv) was added DCM ( 80 ml ) and the mixture stirred at ambient temperature for 18 h . The solution was then filtered and the DCM was removed under vacuum. The resulting solid was washed with petrol and $\mathrm{Et}_{2} \mathrm{O}$ (alternatively, toluene may be substituted successfully) was added ( $2 \times 30 \mathrm{ml}$ ) to extract the desired complex. The $\mathrm{Et}_{2} \mathrm{O}$ was removed under vacuum to give a yellow solid in $70 \%$ yield. It was recrystallised from MeOH at $5{ }^{\circ} \mathrm{C} .{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): $7.50\left(\mathrm{br}, 1 \mathrm{H}, \mathrm{im}_{2 / 3}\right.$ ), $7.40\left(\mathrm{br}, 2 \mathrm{H}, \mathrm{im}_{2 / 3}\right), 7.20\left(\mathrm{br}, 1 \mathrm{H}, \mathrm{H}_{\mathrm{Ar}}\right), 7.16\left(\mathrm{br}, 1 \mathrm{H}, \mathrm{H}_{\mathrm{Ar}}\right), 7.10\left(\mathrm{br}, 1 \mathrm{H}, \mathrm{H}_{\mathrm{Ar}}\right), 4.30(\mathrm{~s}, 3 \mathrm{H}$, Me ), 2.9 (br, $1 \mathrm{H}, \mathrm{CH}_{11 / 14}$ ), 2.65 (br, $1 \mathrm{H}, \mathrm{CH}_{11 / 14}$ ), 1.40-1.20 (br, $6 \mathrm{H}, \mathrm{CH}_{3}$ ), 1.10 (br, $3 \mathrm{H}, \mathrm{CH}_{3}$ ),
0.90 (br, $3 \mathrm{H}, \mathrm{CH}_{3}$ ) ppm. ${ }^{13} \mathrm{C}$ NMR ( $75.57 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): 187.0 (d, J=37.5, C), 144.0 (s, C), 131.0 ( $\mathrm{s}, \mathrm{CH}$ ), 130. ( $\mathrm{s}, \mathrm{CH}$ ), 125.5 ( $\mathrm{s}, \mathrm{CH}$ ), 124.5 ( $\mathrm{s}, \mathrm{CH}$ ), 122.0 ( $\mathrm{s}, \mathrm{CH}$ ), 121.6 ( $\mathrm{s}, \mathrm{CH}), 39.4$ ( $\mathrm{s}, \mathrm{Me}$ ), $22.0\left(\mathrm{~d}, \mathrm{~J}=15, \mathrm{CH}\right.$ ), $21.0\left(\mathrm{br}, \mathrm{CH}_{3}\right), 16.5\left(\mathrm{~s}, \mathrm{CH}_{3}\right), 15.8\left(\mathrm{~s}, \mathrm{CH}_{3}\right), 14.5\left(\mathrm{br}, \mathrm{CH}_{3}\right), 13.9$ (s, $\mathrm{CH}_{3}$ ) ppm. ${ }^{31} \mathrm{P}$ NMR ( $121.7 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): 48.4 ppm . MS (ES+): M/z; $512\left[\mathrm{M}+\mathrm{NH}_{4}{ }^{+}\right]$, 411.2 [M-2H-Br]. X-Ray: Single crystals of magnesium complex $\mathbf{3 . 8}$ were obtained from a saturated solution in methanol $(\mathrm{MeOH})$ at $5^{\circ} \mathrm{C}$.

## Synthesis of mono-(phosphine-carbene) Ir complex (3.9):

## (Via Free Carbene):

To a mixture of phosphine-imidazolium salt (2.5) ( $0.1 \mathrm{~g}, 0.248 \mathrm{mmol}$ ) (1 equiv.) and $\mathrm{KN}\left(\mathrm{SiMe}_{3}\right)_{2}(0.055 \mathrm{~g}, 0.273 \mathrm{mmol})$ ( 1.1 equiv.) was added pre-cooled THF ( 50 ml at $-78{ }^{\circ} \mathrm{C}$ ). The resulting mixture was stirred at this temperature for 10 min . and then added via a cannula to a pre-cooled solution of the iridium precursor $[\operatorname{IrCl}(\mathrm{COD})]_{2}(0.083 \mathrm{~g}, 0.124 \mathrm{mmol})(0.5$ equiv.) in THF ( 30 ml ). The mixture was left stirring at this temperature for another 10 min . and then allowed to reach ambient temperature and stirred for 18 h . The solvent was removed in vacuo and the solid was extracted with DCM. The DCM was removed in vacuo and the crude complex was extracted twice with $\mathrm{Et}_{2} \mathrm{O}(2 \times 30 \mathrm{ml}) . \mathrm{Et}_{2} \mathrm{O}$ was then removed under vacuum to give a red-brown solid. ${ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta\right): 7.4\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{H}_{\mathrm{Ar}}\right), 7.30(\mathrm{~m}$, $2 \mathrm{H}, \mathrm{im}_{2,3}$ ), $7.20\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{H}_{\mathrm{Ar}}\right), 4.35(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Me}), 2.40\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{CH}_{11 / 14}\right), 2.25\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{CH}_{11 / 14}\right)$, 2.05-1.80 (br, COD, $\mathrm{CH}_{2}$ ), 1.70-1.05 (br, $6 \mathrm{H}, \mathrm{CH}_{3}$ ), $0.90\left(\mathrm{~m}, 3 \mathrm{H}, \mathrm{CH}_{3}\right.$ ), 0.60-0.40 (br, 3 H , $\mathrm{CH}_{3}$ ) ppm. ${ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}, \delta$ ): $167.8(\mathrm{~s}, \mathrm{C}), 144.0(\mathrm{~d}, \mathrm{~J}=10.2, \mathrm{C}), 129.5(\mathrm{~s}, \mathrm{CH})$, 128.8 (d, J=27.8, CH), 128.4 ( $\mathrm{s}, \mathrm{CH}$ ), 126.2 (d, J=3.9, CH), 124.1 ( $\mathrm{s}, \mathrm{CH}$ ), 122.4 (d, J=4.9, CH ), 119.9 ( $\mathrm{s}, \mathrm{CH}$ ), $43.4\left(\mathrm{~s}, \mathrm{CH}_{2}\right), 38.7\left(\mathrm{~s}, \mathrm{CH}_{3}\right.$ ), $28.0(\mathrm{~s}, \mathrm{CH}), 18.7$ (br, $\mathrm{CH}_{3}$ ), 16.5 (br, $\mathrm{CH}_{3}$ ), $14.0(\mathrm{~s}, \mathrm{CH}), 11.0(\mathrm{~s}, \mathrm{CH}) \mathrm{ppm} .{ }^{31} \mathrm{P}$ NMR ( $121.7 \mathrm{MHz}, \mathrm{CDCl} 3, \delta$ ): $0.4 \mathrm{ppm} . \mathrm{MS}(\mathrm{ES}+): \mathrm{M} / \mathrm{z}$; $573.2[\mathrm{M}-\mathrm{H}]$.

# Chapter 4 

Other Attempted Complexations

## 4. Other attempted complexations

## Attempted synthesis of NHC-phosphine complexes of Groups 4, 6, 7, 8, 9 and 10 metals:

This chapter is concerned with attempted complexation of a series of the chelating carbene-phosphine ligand, 2.5, with some metals of Groups $4,6,7,8,9$ and $10: \operatorname{Ti}(I V), \operatorname{Cr}(3)$, $\mathrm{Mn}(\mathrm{II}), \mathrm{Fe}(\mathrm{II}), \mathrm{Ru}(\mathrm{II}), \mathrm{Co}(\mathrm{II}), \mathrm{Rh}(\mathrm{I}), \operatorname{Ir}(\mathrm{I}), \mathrm{Pt}(\mathrm{II}), \mathrm{Pd}(\mathrm{II})$. The reactions listed below are for the failed experiments. Ligand $\mathbf{2 . 5}$ was reacted with other metal precursors under the same conditions that were used to obtain the complexes presented and discussed in Chapter 3. General comments and materials are detailed in the experimental sections in Chapter 2 and 3.

The same work-up methodology as previously reported, in chapter 3, for complexes synthesised by the formation of free carbene (via free carbene) or via transmetallation was followed. Metal precursors, $\mathrm{TiCl}_{4}(\mathrm{THF})_{2}, \mathrm{Ti}\left(\mathrm{NMe}_{2}\right)_{4}, \mathrm{CrCl}_{3} .3 \mathrm{THF},\left[\mathrm{Mn}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{4}\right]\left(\mathrm{BF}_{4}\right)_{2}$, $\left[\mathrm{Fe}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left(\mathrm{BF}_{4}\right)_{2}, \mathrm{Ru}(\mathrm{DMSO})_{4} \mathrm{Cl}_{2}, \mathrm{RuCl}_{2}\left(\mathrm{PPh}_{3}\right)_{3}, \mathrm{RuCl}_{2}(\text { cymene })_{4},\left[\mathrm{Co}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left(\mathrm{BF}_{4}\right)_{2}$, $\mathrm{Rh}_{2} \mathrm{Cl}_{2}(\mathrm{COD})_{2}, \mathrm{Rh}_{2} \mathrm{Cl}_{2}(\mathrm{CO})_{4}$, and $\mathrm{Ir}_{2} \mathrm{Cl}_{2}(\mathrm{COT})_{4}$, were reacted with the ligand, 2.5, via the formation of free carbene. Rh and Ir precursors, $\mathrm{Rh}_{2} \mathrm{Cl}_{2}(\mathrm{COD})_{2}, \mathrm{Rh}_{2} \mathrm{Cl}_{2}(\mathrm{CO})_{4}, \mathrm{Ir}_{2} \mathrm{Cl}_{2}(\mathrm{COD})_{2}$ and $\mathrm{Ir}_{2} \mathrm{Cl}_{2}(\mathrm{COT})_{4}$, were also reacted with the ligand, 2.5, by transmetallation from the corresponding $\mathrm{Ag}(\mathrm{I})$ complex 3.2.

Via free carbene, a phosphine-imidazolium salt, 2.5, was reacted with one equivalent of base of $\mathrm{KN}\left(\mathrm{SiMe}_{3}\right)_{2}$ in THF at $-78{ }^{\circ} \mathrm{C}$. The imidazolium salt was deprotonated by the base to form the carbene. The deprotonation was complete in about 15 minutes and the solution was added into a second Schlenk containing one equivalent of the metal precursors. The mixture was stirred at this temperature for another ten minutes and then allowed to reach ambient temperature and stirred for 18 hours. In case the product was dissolved in the solution, THF was evaporated, and DCM was added to extract the crude product which was extracted by the addition of $\mathrm{Et}_{2} \mathrm{O}$. In case the product was solid, the precipitated solid was filtered and washed with THF and $\mathrm{Et}_{2} \mathrm{O}$ and then extracted into DCM. The DCM was removed under vacuum to give the product. The isolated solids were investigated by ${ }^{31} \mathrm{P}\{\mathrm{H}\}$ NMR to check on their purity.

Via Transmetallation, to a mixture of a metal precursor and the silver adduct of the carbene-phosphine complex, 3.2, was added DCM and the mixture left to stir at r.t. for 18 h . The solution was filtered. DCM was removed under vacuum and the resulting solid was washed with $\mathrm{Et}_{2} \mathrm{O}$. The resulting solid was recrystallised from $\mathrm{DCM} / \mathrm{E}_{2} \mathrm{O}$ to give a product which was then dried under vacuum.

In all cases below, either no reaction occured or multiple unidentified products were obtained and the reaction did not lead to isolable complexes or other tractable products. Via the formation of free carbene, metal precursors of $\mathrm{Ti}, \mathrm{Cr}$ and Mn were added under the same conditions mentioned in Chapter 3. No meaningful results were obtained because of no reaction apparently occurred as shown in Scheme 4.1. The mixture was left under reflux overnight and no results were obtained. As for no reaction occurs which is given in schemes below, no characteristic changes were observed between reactants and products in all the ${ }^{1} \mathrm{H}$, ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ and ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ spectroscopic techniques.

Scheme 4.1: Reaction of Ti, Cr and Mn precursors with the free ligand, 2.5, via free carbene

From Group 8, Fe and Ru precursors were reacted with the free ligand, 2.5. The reaction was conducted via the formation of free carbene under the same conditions used in Chapter 3. In the case of $\left[\mathrm{Fe}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left(\mathrm{BF}_{4}\right)_{2}$ and $\mathrm{RuCl}_{2}(\text { cymene })_{4}$, no reaction occurred. However, products with $\mathrm{Ru}(\mathrm{DMSO})_{4} \mathrm{Cl}_{2}$ and $\mathrm{RuCl}_{2}\left(\mathrm{PPh}_{3}\right)_{3}$ gave multiple unidentified products, from which it was impossible to obtain isolable products, Scheme 4.2. The products
were characterized by ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$-NMR, but gave multiple unidentified products' spectra. Thus, it was not possible to characterize with ${ }^{1} \mathrm{H}-\mathrm{NMR}$ technique due to formation of the multiple products. Attempted recrystalization of the products with different combination of solvents proved futile.

Scheme 4.2: Reaction of Fe and Ru precursors with the free ligand, $\mathbf{2 . 5}$, via free carbene

From Group 9, metal precursors of Co , Rh and Ir , $\left[\mathrm{Co}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{6}\right]\left(\mathrm{BF}_{4}\right)_{2}$, $\mathrm{Rh}_{2} \mathrm{Cl}_{2}(\mathrm{COD})_{2}, \mathrm{Rh}_{2} \mathrm{Cl}_{2}(\mathrm{CO})_{4}, \mathrm{Ir}_{2} \mathrm{Cl}_{2}(\mathrm{COD})_{2}$ and $\mathrm{Ir}_{2} \mathrm{Cl}_{2}(\mathrm{COT})_{4}$, were used. With cobalt precursor, no complexation occurred with the free ligand, 2.5, by the method of free carbene formation, Scheme 4.3. Both free carbene and transmetallation methods were applied to Rh precursors and resulted in mixtures having multiple unidentified products' spectra. An addition of the Rh precursors to the ligand before the addition of the base, $\mathrm{KN}\left(\mathrm{SiMe}_{3}\right)_{2}$, was not a successful trial to achieve complexation. All attempted trials failed to purify and isolate expected products, Scheme 4.3.

 $I^{\ominus}$

Scheme 4.3, Reaction of Co and Rh precursors with the free ligand, 2.5, via free carbene and via transmetallation

Similarly, for Ir precursors, methods via free carbene and via transmetallation were used and resulted in having multiple unidentified products' spectra. Addition of the Ir precursors to the ligand before the addition of the base, $\mathrm{KN}\left(\mathrm{SiMe}_{3}\right)_{2}$, was not a successful trial to achieve purer complexation. Efforts failed to purify and isolate desired products, Scheme 4.4.

Scheme 4.4: Reaction of Ir precursors with the free ligand, 2.5, via free carbene and via transmetallation

In absence of a base, reaction of the ligand, 2.5, with $\mathrm{K}_{2}\left(\mathrm{PdCl}_{4}\right)$ and $\mathrm{K}_{2}\left(\mathrm{PtCl}_{4}\right)$ precursors showed no sign of reaction or multiple unidentified products' spectra. Attempts of purification did not lead to isolable complexes or other tractable products, Scheme 4.5.

Scheme 4.5: Reaction of Pd and Pt precursors with the free ligand, 2.5, via free carbene and via transmetallation

## Recommendation for future work

Future research should be focused on preparation of mono NHC-phosphine complexes, investigation of new synthetic methods for better yields, optimization for rapid and clean reactions with minimal waste and by-products, modification to the imidazolium ring substituents to alkyl or aryl groups, extending the coordination chemistry to include systems where only one of the donors, phosphine or carbene is bound, possibility of bimetallic systems where the NHC binds one metal and the P donor another, extending the coordination chemistry to other metals including main group compounds, modification to the imidazolium ring substituents at $\mathrm{C}_{3}$ and $\mathrm{C}_{4}$ positions, looking at synthetic routes to ligands with different linking groups between the imidiazolium ring and the phosphine, having more bulky groups for phosphine substituents, and study of the catalytic behavior of these complexes.
$N$-heterocyclic carbenes-phosphine complexes have electronic and steric properties suitable for effective catalysis as both phosphines and NHCs have been very successful in this area. One application I had in mind was hydrogenation (addition of pair of hydrogen atoms to a molecule, generally an alkene). Hydrogenation plays an essential role in food, petrochemical, pharmaceutical, and agricultural industries. Other relevant possible applications in homogeneous catalysis are hydrosilylation, hydroamination, carbon-carbon bond forming reactions through cross-coupling and alkene metathesis (Grubbs' type) as well as their application in a range of other synthetically useful reactions. Further research is recommended in this area.

## Experimental

Single crystals of $\mathrm{C}_{18} \mathrm{H}_{28} \mathrm{~N}_{2} \mathrm{IPO}$ were recrystallised from tetrahydrofuran (THF) mounted in inert oil and transferred to the cold gas stream of the diffractometer.

## Crystal structure determination

Crystal Data. $\mathrm{C}_{18} \mathrm{H}_{28} \mathrm{~N}_{2}$ IPO, $M=446.29$, Monoclinic, $a=10.062(5) \AA, b=9.235(5) \AA, c=$ $21.923(5) \AA, \beta=98.366(5)^{\circ}, U=2015.5(16) \AA^{3}, T=150(2)$, space group $\mathrm{P} 2_{1} / \mathrm{n}$ (no. 14), $Z=$ $4, \mu(\mathrm{Mo}-\mathrm{K} \alpha)=1.674,6548$ reflections measured, 3527 unique $\left(R_{\mathrm{int}}=0.0298\right)$ which were used in all calculations. The final $w R\left(F_{2}\right)$ was 0.0653 (all data).

## Experimental

Single crystals of $\mathrm{C}_{32} \mathrm{H}_{46} \mathrm{I}_{2} \mathrm{P}_{2} \mathrm{NiN}_{4}$ were recrystallised from ethanol (EtOH) mounted in inert oil and transferred to the cold gas stream of the diffractometer.

## Crystal structure determination]

Crystal Data. $\mathrm{C}_{32} \mathrm{H}_{46} \mathrm{I}_{2} \mathrm{P}_{2} \mathrm{NiN}_{4}, M=897.21$, Monoclinic, $a=8.7370(2) \AA, b=39.0870(7) \AA$, $c=10.9220(2) \AA, \beta=100.4400(10)^{\circ}, U=3668.15(13) \AA^{3}, T=150(2)$, space group $\mathrm{P} 2_{1} / \mathrm{c}$ (no. 14 ), $Z=4, \mu(\mathrm{Mo}-\mathrm{K} \alpha)=2.333$, 19169 reflections measured, 7864 unique ( $R_{\mathrm{int}}=0.0736$ ) which were used in all calculations. The final $w R\left(F_{2}\right)$ was 0.1816 (all data).

Data Set 4: Platinum complex crystal data and structure refinement, 3.6

| Identification code | pge0704 |
| :--- | :--- |
| Empirical formula | $\mathrm{C}_{32} \mathrm{H}_{44} \mathrm{I}_{2} \mathrm{P}_{2} \mathrm{PtN}_{4}$ |

## Experimental

Single crystals of $\mathrm{C}_{32} \mathrm{H}_{44} \mathrm{I}_{2} \mathrm{P}_{2} \mathrm{PtN}_{4}$ were recrystallised from methanol (MeOH) mounted in inert oil and transferred to the cold gas stream of the diffractometer.

## Crystal structure determination

Crystal Data. $\mathrm{C}_{32} \mathrm{H}_{44} \mathrm{I}_{2} \mathrm{P}_{2} \mathrm{PtN}_{4}, M=995.54$, Monoclinic, $a=15.5350(2) \AA, b=13.7400(2) \AA$, $c=19.6770(3) \AA, \beta=91.070(1)^{\circ}, U=4199.34(10) \AA^{3}, T=150(2)$, space group $\mathrm{P} 2_{1} / \mathrm{c}$ (no. 14), $Z=4, \mu(\mathrm{Mo}-\mathrm{K} \alpha)=4.911,71044$ reflections measured, 12250 unique $\left(R_{\mathrm{int}}=0.1104\right)$ which were used in all calculations. The final $w R\left(F_{2}\right)$ was 0.1050 (all data).

Data set 5: Manganese complex crystal data and structure refinement, 3.8

| Identification code | pge0811 |

## Experimental

Single crystals of $\mathrm{C}_{19} \mathrm{H}_{23} \mathrm{PO}_{3} \mathrm{BrMnN}_{2}$ were recrystallised from methanol ( MeOH ) mounted in inert oil and transferred to the cold gas stream of the diffractometer.

## Crystal structure determination

Crystal Data. $\mathrm{C}_{19} \mathrm{H}_{23} \mathrm{PO}_{3} \mathrm{BrMnN}_{2}, \quad M=535.68$, Monoclinic, $a=27.4450(6) \AA, \quad b=$ $8.7250(2) \AA, c=18.6360(4) \AA, \beta=100.840(2)^{\circ}, U=4382.90(17) \AA^{3}, T=150(2)$, space group $\mathrm{C} 2 / \mathrm{c}$ (no. 15), $Z=8, \mu(\mathrm{Mo}-\mathrm{K} \alpha)=2.644,8358$ reflections measured, 5010 unique $\left(R_{\mathrm{int}}=\right.$ 0.0346 ) which were used in all calculations. The final $w R\left(F_{2}\right)$ was 0.0898 (all data).

[^0]:    * Note: in all new crystal structures reported in this chapter, the carbene's carbon attached to the metal is denoted as $\mathrm{C}_{1}$ in the numbering scheme.
