Introduction

Operations Management (OM) as a management field dates back at least a century (Sprague, 2007), while the related area of Supply Chain Management (SCM) has developed rapidly and more recently with its genesis often identified as the 1980s (Singhal and Singhal, 2012). The relationship between the two is such that academics increasingly refer to the operations and supply chain management (OSCM) field (Roth et al., 2016), although the nature of the relationship between the two elements is subject to debate. This paper aims to investigate the diversity of this unified ecosystem both at the level of intellectual structure and of the demographics of individual academics. In so doing we aim to shed light on the relationships between SCM and OM; and on the gender, business school affiliations and geographical distributions of academics involved in journal governance.

Although past contributors to OSCM research demonstrated the dynamism of the field's intellectual structure (e.g. Pilkington and Meredith, 2009; Shiau et al., 2015), they paid scant attention to charting the academic communities that form the collective and fuel its vibrancy. Rather than adopting a social perspective, researchers concentrated on mapping intellectually their domains with studies focused on the knowledge content of journals. Our approach captures the social communities comprising the OSCM field and underpinning the field's knowledge structures. Using social network analysis (SNA) (Wasserman and Faust, 1999; Scott, 2003) we connect OSCM journals, academics and institutions by analysing the interlocking membership of journal governance systems referred to as editorial advisory boards (EABs). The study addresses the research question: how do the interlocking EABs of OSCM journals map out the field's diverse academic communities and how demographically diverse is the field and its communities?

Thirty eight journals representing the OSCM field are allocated to seven communities by SNA of EAB members. We contrast the social structure of communities with prior studies of intellectual structure. These communities form two larger groupings of a core and periphery in the social network. Our analysis identifies the SCM community as a substantial constituency occupying a key position near the centre of the modern OSCM field; but surprisingly this community includes EAB members from the Journal of Operations Management. We show the OSCM field's lack of diversity given its domination by males affiliated with business schools and with USA-based organisations.

First we deal with the literature on academic fields and on mapping their intellectual structures, making some general comments before paying particular attention to previous

1
2
3 studies in OSCM. Next we outline the SNA methodology and how we collected the data.
4 Then we present our findings, discuss these and conclude by covering study implications,
5 limitations and suggestions for further research.

9

10 **Literature Review**

11 First some general remarks are made about academic fields and how to map their intellectual
12 structures before concentrating on the OSCM field. These comments cover studies that
13 identify a field's intellectual structure by linking together the knowledge content of published
14 artefacts and examining such as the frequency that topics occur in the knowledge structure.
15 An alternative to this knowledge-content-perspective involves studying the social
16 connections between academics, for example through co-authoring publications or co-
17 attending conferences. For such a grouping of connected academics we use the term
18 "community". In this study we are interested in the communities within an academic field;
19 such an individual community can combine a single discipline, multiple disciplines – or even
20 simply an element of a discipline.

30 *Academic fields*

31 According to Jenkins (2007 p. 84) "A field, in Bourdieu's sense, is a social arena within
32 which struggles or manoeuvres take place over specific resources or stakes and access to
33 them". Becher and Trowler (2010) in their landmark study view academic fields as often
34 comprising single or multiple disciplines; and go on to link their cognitive and social aspects.
35 Whitley (2000), in his influential work on analysing the intellectual and social organisation of
36 the sciences, uses the term "field" for management and business studies; an area constituted
37 by multiple disciplines; and identifies areas such as Operations Research (OR), and therefore
38 presumably OSCM, as sub-fields. He identifies management and business in recent times as
39 becoming more fragmented and diverse – a view that is added to by the many critiques of the
40 state of this academic area (e.g. Hamel, 2007). Whitley recognises various factors that have
41 allowed specialisms to flourish; these factors include the continued expansion of higher
42 education systems and the reduced influence of US-based companies and related economic
43 systems. In his terms Management Studies is a fragmented adhocracy where the sub-fields
44 have low strategic and functional dependence; i.e. areas such as OSCM tend to be only
45 loosely connected to other areas. Because OSCM is the focus of this paper, for ease of
46 description we describe it as a field and the communities comprising OSCM as sub-fields.

7

8 *Mapping intellectual and social structures*

9
10 In academia many researchers have studied the intellectual structure of their fields and
11 disciplines; and such studies appear to be carried out more frequently in the social sciences as
12 fields mature and research styles become more reflexive. Often researchers analyse the
13 content of academic journals to establish how knowledge in a particular academic domain is
14 partitioned and connected. Although knowledge also resides in artefacts other than journals,
15 e.g. conference papers, books, etc.; many fields and disciplines prioritise journal articles over
16 other knowledge sources. Past approaches to analysing such knowledge sources have
17 included subjective classification of journal content, citation/co-citation analysis (CCA)
18 (Cawkell, 2000) and, more recently, forms of co-word analysis, e.g. latent semantic analysis
19 (LSA) (Larsen et al., 2008). These study types select their base data from various sources
20 within journals including: titles, abstracts, keywords, article content, and citations. Related
21 studies of journals are often, and increasingly, carried out to determine how community
22 members rank and rate their journals. For example, Barman et al. (2001) carried out a survey
23 of OM academicians to ascertain how they rank the quality and relevance of OM journals.

30
31
32

33 One way of illuminating how individual authors, and groups, link together to form
34 academic communities is to carry out co-authorship studies of journal papers (Behara et al.,
35 2014). Recently, Burgess and Shaw (2010) and Baccini and Barabesi (2010) introduced a
36 new approach to studying academic communities by applying SNA (Wasserman and Faust,
37 1999; Scott, 2013) to data for academics occupying formal roles in journal governance
38 systems. Burgess and Shaw's study examined the links between the main academic fields
39 comprising management and business by investigating the Financial Times 40 list of top
40 journals (since then the Financial Times list has expanded to 45) while the study of Baccini
41 and Barabesi focused on the single field of Economics.
42
43
44
45
46
47

48 The rationale for studying EAB members stems from their recognised role as
49 academic gatekeepers. Individuals are invited on to EABs for a variety of reasons but
50 generally-expressed views suggest that a major reason is that they are seen as high status
51 individuals within the journal's disciplinary or topic catchment area (Bedeian et al., 2009)
52 and therefore suitable gatekeepers for the journal's academic values. Clearly individuals who
53 serve on the same EAB are linked by their association with the journal and with aspects such
54 as the journal's academic interests. Where an individual serves on two or more boards then
55
56
57
58
59
60

1
2
3 this can be taken to link the boards (and journals) by virtue of them possessing similar
4 academic interests. Such links can be used to structure the field into a network of various
5 communities derived from the degree of similarity between the board members (and journals).
6
7 This type of journal study focusing on EAB interlocks, is analogous to the study of
8 companies through board interlocks; an approach that has been around for many years (for a
9 review see Mizruchi, 1996). The affinity described above between EAB members can be
10 explained theoretically in a number of ways. In a fundamental sense the concept of
11 homophily (McPherson et al., 2001) can be invoked from Social Network Theory, i.e. where
12 social actors prefer to link with other actors that they see as similar to themselves. In a more-
13 sociologically-specific manner we can use the Bourdieu-informed approach adopted by
14 Burgess and Shaw (2010). Briefly, in this perspective academic fields are socially stratified
15 with a self-reproducing elite (the editorial advisory board) dominating the non-elite members
16 of the field.
17

18
19 This study is focused on the broad editorial group that is connected to a journal rather
20 than in a narrowly-focused editorial team (Burgess and Shaw, 2010). While not denying the
21 particular influence of the editor-in-chief, or a small editorial team, this focus reflects that
22 SNA is used in this study to trace the connections linking broad communities within a
23 particular academic field.
24

25 26 27 28 29 30 31 32 33 34 35 ***Intellectual structure of operations and supply chain management***

36 The OM field grew historically out of Production Management and Factory Management
37 whose origins can be traced back to the start of the twentieth century (Meredith and Amoako-
38 Gyampah, 1990; Bayraktar et al., 2007; Singhal et al., 2007; Sprague, 2007; Piercy, 2012).
39 Along the way OM has been infused by other areas such as service (Levitt, 1972; Levitt,
40 1976), quality, computers, just-in-time (JIT), materials requirements planning (MRP), and
41 supply chain management (SCM) (Bayraktar et al., 2007). Since SCM's origins in the 1980s
42 (Singhal and Singhal, 2012), the relationship of SCM and OM has been subject to discussion
43 and debate. Some see SCM as the latest area to integrate within OM while others might see
44 the future as OM being incorporated within SCM. In this paper we adopt a perspective that
45 brings OM and SCM together in the ecosystem of operations and supply chain management
46 (OSCM) (Roth et al., 2016).
47

48 The evolution of OSCM can be studied by mapping the field's intellectual structure,
49 as discussed in general in the earlier section. Buffa (1980) is credited with early attempts to
50 describe OM's intellectual structure. Further literature has accumulated since this early
51
52
53
54
55
56
57
58
59
60

1
2
3 contribution and Table 1 contains some influential studies that typify the accumulated
4 literature on the structure of the OSCM field and its evolution. These studies include reviews
5 of academic articles and wider literature such as books (Buffa, 1980; Mabert, 1982; Amoako-
6 Gyampah and Meredith, 1989; Barman et al., 1991; Neely, 1993; Pannirselvam et al., 1999)
7 and surveys of academic opinions (Miller et al., 1981; Voss, 1984; Meredith and Amoako-
8 Gyampah, 1990; Scudder and Hill, 1998). In recent times more 'scientific' methods have
9 been deployed; in particular citation analysis (CA) and, more latterly, co-citation analysis
10 (CCA) have figured widely as approaches (Goh et al., 1996; Vokurka, 1996; Pilkington and
11 Liston-Heyes, 1999; Vastag and Montabon, 2002; Pilkington and Fitzgerald, 2006; Petersen
12 et al., 2011). Even more recently other approaches have been used, e.g. LSA which Kulkarni
13 et al. (2011) used to identify the major topics and methods in IJOPM articles over a thirty
14 year period.
15
16
17
18
19
20
21
22

23 Table 1 about here

24 Analysis of these example studies suggests they focus typically on classifying the knowledge
25 content of academic articles into representative categories; with a key interest in observing
26 how the field has changed over time (e.g. see Buffa, 1980). The differences in study methods
27 and data sources used, coupled with the different dates of the various studies, mean they
28 differ in the knowledge groups identified. Nevertheless, some common strands can be
29 observed in studies published in the last two decades. The main knowledge groups have
30 included: manufacturing strategy, planning and control (particularly at the tactical level),
31 performance measurement, product and process design, lean, quality and supply chain
32 management (SCM). Over the last two decades topics such as tactical planning and control,
33 and manufacturing strategy have reduced in popularity while SCM and quality management
34 have increased. Notwithstanding these changes, manufacturing strategy was recently still the
35 main preoccupation of journal articles (Pilkington and Meredith, 2009). But a key point is
36 the perceived increase in importance of SCM (Pannirselvam et al., 1999; Chopra et al., 2004;
37 Pilkington and Fitzgerald, 2006; Craighead and Meredith, 2008; Pilkington and Meredith,
38 2009; Petersen et al., 2011; Singhal and Singhal, 2012). In their contribution Singhal and
39 Singhal (2012) point to theoretical explanations that can be called upon to explain how a
40 particular area of new knowledge, such as SCM, can appear, grow and potentially supplant
41 the existing dominant area (Eldredge and Gould, 1972; Kuhn, 1996).

57
58
59
60

1
2
3 While knowledge content of journal articles is important to know about and to track over
4 time, academic articles are produced by social processes which themselves are important to
5 observe and understand since they can explain the unfolding of knowledge content, or any
6 ebbs and flows that occur. Such a view is consistent with the work of Whitley (2000) on
7 intellectual and social organisation but is also raised by OSCM contributors. Saladin (1985)
8 suggested a wider view of OM should reflect this social nature and include the influence of
9 academics and practitioners, while Goh et al. (1996) outlined the need for any discipline to
10 examine its communications.
11
12

13
14
15
16 Methods such as CA and LSA are based on citations that occur usually within a
17 narrow group of journals and point to articles published in a wider spread of journals.
18 Although CA is not designed to address the influence of social groups within an academic
19 field, and the focus on a narrow spread often means that studies do not address a whole field;
20 the method provides useful evidence of ‘social linkages’ between authors (Vastag and
21 Montabon, 2002 p. 114). Pilkington and Meredith (2009) combined citation analysis, and co-
22 citation analysis, with SNA to visualise the OM community, thus pursuing the idea of OM
23 academic influence being shaped by distinct social groups. Unlike previous attempts which
24 sought to outline key topics, categories or most important journals, Pilkington and Meredith
25 attempted to map more fully the field’s intellectual structure. They used citations to visualise
26 the major knowledge groups and to map the development of citation and research groupings
27 over time.
28
29

30
31
32
33 However, although the work of such as Pilkington and Meredith focuses on links
34 between OM authors; little work, if any, has examined the social links between journal EABs
35 in OSCM. Clearly the two are linked; the editorial board influences which authors are
36 published in a journal; while authoring articles in a journal can lead to membership of its
37 EAB. However as indicated earlier, SNA of EAB linkages is an alternative and growing
38 method of structuring a field; and one that focuses on the gatekeepers rather than the
39 authoring community within a field.
40
41

42
43
44
45 The previous sections have demonstrated that SCM is an area of growing importance
46 in the field’s intellectual structure. This raises queries allied to how SCM figures in the
47 field’s social organisation. For example how is SCM structured as a community and how
48 does it relate to other communities within the field – i.e. to what extent does it contribute to
49 forming a diverse or a uniform OSCM field? One of the key concerns with field structures is
50 how diverse they are; for example, questions can be asked such as what might be the volume
51 and variety of knowledge topics within a field or how many separate communities can be
52
53
54
55
56
57
58
59
60

1
2
3 identified? In fields other than OSCM, e.g. Management Information Systems (MIS), the
4 intellectual diversity of the field has been a more controversial topic and featured
5 substantially in the field's literature. In a recent piece celebrating 50 years of the MIS field,
6 Hirschheim and Klein (2012 p. 193) commented that diversity "is widely accepted as a
7 hallmark of the field". Diversity covers a wider context than just knowledge structures
8 (intellectual diversity); as McGrath et al. (1995) point out, one of the diversity categories is
9 demographic characteristics such as: age, ethnicity, sexual orientation, physical status,
10 religion and education. However the diversity of the intellectual structure connects to
11 demographic diversity of the field and of the communities, i.e. aspects such as gender or
12 geographical affiliation of the individual academics conditions in some way their knowledge
13 interests. Gender diversity in academia has attracted the attention of researchers; and
14 commentators such as Metz and Harzing (2009) have specifically examined gender diversity
15 in editorial boards of management journals. Similarly geographic diversity in editorial boards
16 has also been studied (Harzing and Metz, 2012; Harzing and Metz, 2013).

17
18 To recap, the study's primary research question is: how do the interlocking editorial
19 advisory boards (EABs) of operations and supply chain (OSCM) journals map out the field's
20 diverse academic communities and how demographically diverse is the field and its
21 communities?
22
23

24 25 26 27 28 29 30 31 32 33 34 35 **Methodology**

36 For the study data set we took the 40 journals listed in version 4 of the Academic Journal
37 Quality Guide of the UK Association of Business Schools (ABS, 2010) under the category of
38 Operations and Technology Management. However, the sample was reduced to 38 since two
39 journals were duplicated under different names (see Table 2 for the full list of 38 journals
40 included in the study). Details of the journal's EAB members were extracted from the
41 journals' websites; this included name, editorial board role, gender, and organisational and
42 departmental affiliations. The organisational affiliation was used to assign a geographic
43 location to the individual while the departmental affiliation was dichotomized in to business
44 school or not. The data were cross-checked against institutional and personal websites,
45 updated as necessary, and consolidated into an Excel file. Various checks were made of the
46 overall database and preliminary statistical analysis carried out. For the social network
47 analysis three two-mode data files were extracted from the Excel spread-sheet: individuals
48 affiliated to journals (through EAB membership), individuals affiliated to organisations
49 (through employment) and journals linked to organisations (through the organisational
50

2
3 affiliation of the EAB member). These three data matrices were imported into UCINET
4 (Borgatti et al., 1999) and converted for analysis as one-mode data tables (journals,
5 academics and institutions). NETDRAW was used to visualise the data in network diagrams.
6
7 Various SNA measures were determined including network density, node degrees and
8 between-ness. A hierarchical cluster analysis was carried out along with a multi-dimensional
9 scaling plot and these were used to identify the communities comprising the field. The
10 analysis methods are covered in more depth in the results.
11
12
13

14 Table 2 about here
15
16
17

18 **Results**

19 The 38 journals provided data for 1,902 EAB memberships that were occupied by 1,533
20 individuals in 708 organisations located in 59 countries. Table 2 shows that just under half
21 (47%) of the journal's publishers were UK-based while 31.6% had publishers based in other
22 European countries. US societies/ publishers controlled approximately 21% of the journals.
23 Males occupied over 88% of the memberships, and the majority of occupants (i.e. 91%) were
24 located in universities or similar higher education institutions with the remaining 9%
25 affiliated to businesses. Forty nine per cent of the total was affiliated to business schools and
26 39% were affiliated to organisations located in the USA. EAB sizes ranged from 20 to 177
27 with a mean of 50 members per journal (see Table 3¹). The mean "age" of the journals since
28 their establishment was 30 years and the mean ABS score² for journal quality was 2.

39

40 *Journal network structure*

41 Figure 1 presents a sociogram of the journal network, i.e. a standard SNA (Wasserman and
42 Faust, 1999; Scott, 2013) method of presentation. Each circle in the diagram is a node that
43 represents a social actor, in this case a journal. A line connecting two nodes (journals) is a
44 relational tie (Wasserman and Faust, 1999) and in this case signifies at least one person who
45 sits on the EABs of both journals, i.e. a board interlock. Hence this is a binary (or
46 dichotomized) network since a link either exists or it does not. A line in this network
47 diagram is referred to as undirected tie since the lines do not portray any direction to the
48 association between the nodes. A journal with a high number (degree) of ties to other
49
50
51
52
53
54

55
56 ¹ Note that to save space the table is arranged using groupings that are explained later in the analysis.

57 ² The ABS scores are on a 1 to 4 scale where 1 represents modest standard journals and 4 represents top
58 journals in their field.
59
60

1
2
3 journals is positioned toward the centre of the sociogram, while those with few ties are
4 located toward the periphery of the diagram. The software used to plot the sociogram applies
5 a standard algorithm to position the nodes according to their centrality. In social network
6 theory centrality is important (Scott, 2013). In this study high degree centrality means that
7 the journal has EAB members who also sit on many other EABs thus generating many
8 opportunities for information to be exchanged with these other journals and for such as
9 innovatory ideas to be exchanged. Centrality often confers other advantages such as high
10 status. This can be seen in Figure 1 where the shape of the journal node, and its colour,
11 represents its ABS score (see legend). It appears that the higher the journal's ABS score then
12 the more central its position in the network.
13
14
15
16
17
18
19

20 Figure 1 about here

21 Two journals (HCI and IJTM) are not connected to the OSCM network (these are termed
22 isolates) while two other journals (JPA and IJTMSD) are “pendants”, i.e. each only connects
23 to one other journal. The Journal of Operations Management (JOM), with the highest
24 number of ties to other journals (23 out of the maximum 37), lies at the centre of the network.
25 JOM is also the highest ABS scoring journal³ in the network with the maximum score of 4.
26 The density of this binary network is 27.7%, i.e. approximately a quarter of all possible
27 connections between journals are present.
28
29
30
31
32

33 The analysis so far has used degree (the number of other nodes that the individual node
34 connects to) as the measure of centrality; however other centrality measures can be applied
35 (Scott, 2003). Between-ness is another measure that is often used. A node with a high
36 between-ness value signifies that the journal has a strong role as an intermediary that links
37 other journals together. According to Wasserman and Faust (1999) between-ness values
38 indicate the extent of gatekeeping. While JOM has a high between-ness value, two journals
39 (JBL and JPSM) stand out as having even higher between-ness values but without possessing
40 high degree values (see Table 3). This suggests that, although not positioned centrally, the
41 two journals occupy key brokerage roles in the network, i.e. their board members enable
42 communication paths that link pairs of other journals together.
43
44
45
46
47
48
49

50 The journals can also be depicted as a valued network where the number of EAB
51 members shared by each pair of journals is taken in to account in analysing the network (this
52 approach is applied later in the analysis).
53
54
55
56

57 ³ As indicated earlier we used the 2010 version of the ABS list. In the later (2015) version, because of the
58 upgrading of some journals, JOM is not the only journal with the top rating.
59
60

Correlation between study variables

Table 4 presents the Pearson bivariate correlations between the variables listed in Table 3. The size of the EAB is significantly correlated with four other variables. The higher the proportion of board members affiliated to Business Schools and to USA-located organisations then the larger the journal's board membership. The larger the board then the more likely the journal is to be situated centrally in the network and to have a high ABS score.

Table 4 about here

Grouping journals into communities

The journals were grouped into clusters based on a hierarchical cluster analysis (HCA) of the network connections (see Figure 2 for dendrogram) and a multi-dimensional scaling (MDS) plot (Figure 3). We refer to these clusters as communities since they represent clusters of linked individuals within the social network of EAB members. These communities form the sub-fields of the overall OSCM field. The allocation to clusters was achieved by inspecting the HCA plot for groups comprising four or more journals that clustered in close proximity and then confirming this proximity on the MDS plot. We draw attention to one particular allocation that might seem counter-intuitive, namely the allocation of JOM to the group connected with supply and logistics (S&L). On the HCA plot JOM can be seen to be firmly embedded within a group of journals that relate to SCM, i.e. the S&L cluster. The identified clusters were named by taking note of the titles and aims of the journals comprising the cluster. For example, the naming of the supply and logistics cluster of eight journals was informed by four out of the journals having titles containing the word "logistics" while three had "supply" in their title. The clustering and naming was also informed by the authors' views which were grounded in their experience of the OSCM field. Seven out of the 38 journals could not be easily allocated to any of the six clusters given their remoteness on the HCA plot and were therefore allocated to a seventh group of miscellaneous journals. These seven journals included the two pendants and two isolates mentioned earlier in connection with Figure 1. Figure 3 shows the MDS plot with the boundaries of the six main communities superimposed on the diagram.

Figure 2 about here

Figure 3 about here

Five members of the miscellaneous group are not shown on the MDS plot (Figure 3) since they feature as outliers falling outside of the plotted area, i.e. a visual indicator of their poor connection with the other journals. The name of each cluster, or community, reflects the

perceived interests of the journals comprising the cluster and are as follows: (i) computers & production (C&P), (ii) manufacturing & services (M&S), (iii) miscellaneous (M), (iv) operations, performance & systems (OP&S), (v) project & engineering management (P&EM), (vi) quality & process (Q&P) and (vii) supply & logistics (S&L). In Table 3 various characteristics are shown for the individual journals along with their allocations to their communities; while Table 5 shows the journal characteristics aggregated against these communities.

Table 5 about here

The results of the ANOVA (Table 5) show that the communities are similar in terms of journal characteristics such as percentage of EAB members that are male, percentage affiliated to Universities and percentage affiliated to US institutions. The clusters are also similar in terms of the age of their journals, i.e. the time since the journals were established. However, a good number of statistically significant differences exist between the communities including size of EABs, degree, between-ness, business school affiliation, and ABS scores. Next we make some comments against each of the communities.

Computers and production (C&P)

The five journals in this group (CIE, IJCM, IJPE, IJPR and PPC) have a high mean ABS score (2.6), substantially-sized boards and the highest mean degree of any community (15.4); i.e. this group contains journals with the highest number of connections to other journals. The group has the highest percentage male membership (94%). The individual EAB members in this group tend not to be affiliated to business schools; i.e. 72.7% are affiliated to alternatives such as engineering faculties, and the individuals tend not to be drawn from USA-based institutions. Three out of the five journals are in the Elsevier stable with the Netherlands as the home base.

Manufacturing and services (M&S)

This community is composed of four journals (JFMS, JOS, MSOM and POM). Two belong to a German publisher and the other two to a publisher in the UK. The group has the highest ABS score (2.75) of the communities and contains the “youngest” set of journals but the low mean centrality score (6.3) is consistent with their location toward the periphery of the network (top right-hand side of Figure 1).

Miscellaneous (M)

1
2
3 Seven journals form this quasi-community (HCI, IJTM, IJTMSD, JPA, MSQ, PIME and
4 RESS). The group has a low ABS score (1.57), a low membership number per journal, low
5 affiliation to business schools (31.4%), and low affiliation to USA-based organisations
6 (37.1%). The lowest mean centrality score of any group (2.3) indicates that the journals in
7 this group are located at the edge of the network. As commented earlier the group include the
8 two journals that are disconnected from the network (isolates) and the two “pendants” i.e.
9 where a journal is connected to only one other journal.
10
11
12
13
14
15

16 *Operations, performance and systems (OP&S)*

17
18 Five journals comprise this community (IJASM, IJBPM, IJOPM, IJPPM and JMTM) and
19 have the smallest-sized editorial advisory boards measured by members per journal (32.8).
20 The mean ABS score for this group (1.6) is well below the average for the whole data set.
21 Journals in the group display an average membership affiliation to business schools (48.8%)
22 and have the lowest affiliation to USA-based institutions (13.4%) in the field. This could link
23 to the journal publishers being wholly European with two Swiss and three UK publishers.
24 The group has some journals with high centrality measures (mean of 15.0) showing the
25 journals occupy a central position in the network.
26
27
28
29
30
31
32

33 *Project and engineering management (P&EM)*

34
35 The four journals in this community (IEEETEM, IJPM, JCEM and PMJ) are above average
36 size on number of EAB members per journal (58.8 vs. 50.0) and above average on the ABS
37 score (2.25 vs. 2.03). The longest-established journals can be found in this group and overall
38 the group has one of the highest membership affiliations to USA institutions (60.8%). Three
39 out of the four journals are linked to US societies. The community’s low mean centrality
40 score (5.8) reflects their position at the left-hand periphery of the network diagram (see
41 Figure 1).
42
43
44
45
46
47

48 *Quality and process (Q&P)*

49
50 This community contains five journals (BMK, BPMJ, IJQRM, KPM and TQMBE) that are
51 below average in size as measured by mean members per journal (36.8 vs. 50.0) and they
52 have the lowest mean ABS score of the groups (1.40). The community has the highest non-
53 university affiliation (20.2%), although the percentage of university affiliation is still high.
54 The membership affiliation to USA-based institutions is one of the lowest of the communities
55 (28.8%) with four out of five journals having UK-based publishers. The group’s centrality
56
57
58
59
60

score (12.6) is above average for the communities.

Supply and logistics (S&L)

With eight journals, this is the largest community (IJLM, IJLRA, IJPDL, JBL, JOM, JPSM, JSCM and SCM). Overall, the journals in this group also have the highest mean number of board members compared to other groups, thus accentuating their position in the OSCM field. The group's mean ABS score (2.25) is higher than the average (2.03) for the overall field. The group has the highest proportion of members affiliated to business schools (81.8%) and to USA-based institutions (61.1%); and has the highest female proportion of 17.4% (Table 5). Four of the journals have publishers based in the UK, two in the US and two on the European continent. The S&L community has one of the highest levels of connectedness within the network on the basis of degree and has the highest level of between-ness.

Network structure and communities

A typical way of analysing a network is to divide it into a core and a periphery, in our case this means aggregating communities into larger units. We identify C&P, OP&S and S&L as core communities based on having values for both degree and between-ness above the means for the overall set of communities (Table 5). This splits the set of 38 journals into 18 journals in the three core communities and 20 in the four communities on the periphery. The network core can be established in other ways, such as with a clique analysis. The term clique means that every journal in a group is connected to every other journal in the group. Using the journal interconnections, the network's central core comprises a clique of the six journals which have the highest number of connections (degrees) within the network (see Figure 4a). This central core links three journals from the C&P community, two from S&L and one from Q&P.

Figure 4 about here

So far the analysis has simply considered whether ties exist or not between journals. By taking account of the value of the ties, i.e. how many board members are shared by each pair of journals, then the reason for including JOM within the S&L community becomes clearer. Figure 4b shows the connections between those journals with a high strength of tie, i.e. a high number of overlapping board members between two journals. This figure shows only those journals that have more than 11 board members in common between themselves and a second journal. Of the six journals that appear in this figure, five of them are in the S&L group, the other is IJOPM (OP&S community). Figure 4b illustrates a reason for including JOM within

1
2
3 the S&L group, namely its high overlapping board memberships with JBL and JSCM. The
4 figure also shows that the same 42 individuals feature on the EABs of both JBL and
5 IJPDLM; constituting 26.9 percent of the 156 members of the EAB of the former and
6 46.7 percent of the 90 in the latter (Table 3). Why there should be this coincidence is
7 not clear since the journals are linked with different publishers. Both journals cover
8 logistics but so do two other journals (IJLM and IJLRA).
9

10
11
12
13 Figures 4a and 4b portray distinctly different views of the core journals in the field.
14 Both views contain six journals but only one journal, JOM, is common to both. Figure 4b is
15 constituted overwhelmingly by S&L journals while the major community featuring in Figure
16 4a is C&P. In Figure 4b, the S&L journal JBL occupies a central position which conveys an
17 important brokerage role, although the journal is not highly scored by the ABS (i.e. 2). The
18 mean ABS score for the journals in Figure 4a is 3.0 while for Figure 4b it is lower at 2.67. As
19 JOM is the only ABS-scored 4* journal in the 38 journals that comprise the whole OSCM
20 field, then its location in the S&L community has a beneficial outcome of lifting the mean
21 score for this community. Such a marked difference between the two perspectives of the
22 field contained in Figures 4a and 4b highlights that the S&L community differs from the
23 more traditional communities by virtue of the higher number of academics that link their
24 journals together.
25
26
27
28
29
30
31
32

33
34 Figure 5 shows a two-mode sociogram of board members connected to journals (blue
35 squares) for those fifteen board members (red circles) who have four or more board
36 memberships. Eight out of the ten board members shown in Table 9 also appear in Figure 5.
37 Only 11 out of the 38 journals feature in this figure and these are the more connected journals
38 by virtue of each possessing an EAB member who connects to three other journals. A cluster
39 of six of the S&L group (IJLM, IJPDLM, JBL, JPSM, JSCM and SCM) lies at the top centre
40 of the figure surrounded by ten individuals who are linked through EAB membership to at
41 least four out of the six journals. Again this shows the connected nature of S&L journals. Of
42 the two remaining S&L journals (i) IJLRA does not feature at all in the diagram while (ii)
43 JOM is positioned toward the bottom right of the figure to connect with three individuals who
44 also have board memberships with IEEEETEM. At the bottom left are two individuals who
45 link to SCM, IJCIM, JMTM and IJASM.

Figure 5 about here

Individual academics and their demographics

1
2
3 Tables 6 to 9 present various detailed aspects of the data including demographics. Table 6
4 focuses on geographical location while Table 7 gives the locations of the most frequently-
5 affiliated organisations. Table 8 shows the distribution of EAB memberships to individual
6 academics. The vast majority of individuals (86.7%) only have one place on an editorial
7 advisory board in the sampled journal set, while only ten out of the 1,533 individuals in the
8 sample have five or more memberships. The ten individuals comprising this super-elite are
9 listed in Table 9.
10
11

15 Table 7 about here

16 Table 8 about here

17 Table 9 about here
18
19
20
21
22

23 *Gender*

24 For the overall EAB data set 11.6% are female. If EAB members are seen as an elite drawn
25 from all OSCM academics, then editors-in-chief are a super-elite. For the data set 6.1% are
26 female. Those with multiple EAB memberships (as in Tables 8 and 9) can be considered
27 another form of super-elite. It is interesting that three out of the ten academics with the
28 highest multiple EAB memberships, i.e. thirty per cent (Table 9), are female compared to
29 only 11.6 per cent for the overall data set. However, an analysis of all EAB members shows
30 that gender distribution does not significantly vary by number of memberships (Chi square
31 test – see Table 8). Surprisingly Table 4 shows that the percentage of females positively
32 correlates with journal age, i.e. females are more likely to feature in “older” journals.
33
34
35
36
37
38
39
40

41 *Geographic location*

42 Table 6 shows the dominant position of members drawn from USA-based organisations. The
43 table also indicates how the organisations are dominated by those based in English-speaking
44 countries of the world, e.g. the top four entries in the table fall in to this category. In total
45 over two thirds of the memberships are held by individuals affiliated to organisations in
46 countries that have English as the primary language. Table 7 reflects how affiliation to
47 organisations located in the US dominates the list of top ten organisations based on number
48 of EAB memberships. Eight out of ten organisations are located in the US which is nearly
49 twice the proportion of individuals affiliated to US-based organisations in the overall sample.
50 This discrepancy probably reflects a number of factors such as US-based organisations being
51 larger in size than non-US-ones, US universities dominating the world quality rankings for
52
53
54
55
56
57
58
59
60

1
2
3 universities and US universities being prominent in the OSCM field. Four out of the ten
4 super-elite in Table 9 are affiliated to institutions in the US which matches with the 38.7% for
5 the overall data set. The statistical tests reported in Table 8 show that the number of
6 editorships is positively and significantly correlated with the individual's affiliation to USA-
7 based organisation.
8
9

10 11 12 *Business school affiliation*

13
14 The statistical tests reported in Table 8 show that the number of editorships is positively and
15 significantly correlated with the individual's affiliation to a business school. Sixty one
16 percent of editors-in-chief are located in business schools which is higher than the 49% for
17 the whole data set; but this is not statistically significant on a Chi square test.
18
19
20
21
22

23 **Discussion**

24 25 26 ***Finding 1: Applying SNA to journal EABs is a useful and novel method of gaining insight*** 27 ***in to the OSCM field***

28
29 The novel application of SNA to EABs has usefully identified communities within the
30 OSCM field. The method's novelty and scope provides a way of looking at the field that
31 adds to those of previous studies, e.g. the typical studies such as CCA work with a small set
32 of journals and focus on knowledge content. This study's method covers a broad set of
33 journals and specifically uses social connections to mark out communities within the whole
34 of the OSCM field. This focus on the social is a major difference between this method and
35 others which have focused on knowledge content.
36
37
38
39
40

41 However, not all the journal allocations to communities are as strong as others. For
42 example, the M&S community appears more like the amalgamation of two small sub-groups
43 – one contains the business school- and USA-affiliated journals MSOM and POM, and the
44 other contains JFMS and JOS that are affiliated to non-business school and non-USA-based
45 institutions. The allocation to communities made in this study may not align with where
46 journal editorial teams see their journal is positioned. However, we believe our account of
47 the approach serves to explain why we have arrived at our conclusions.
48
49
50
51
52

53 On the whole the communities determined in this study cut across the knowledge
54 groups identified in those previous studies listed in Table 1. For example, the consensus of
55 these previous studies is that the largest knowledge group is manufacturing strategy - but no
56 one journal has a title and/ or purpose that reflects an explicit, sole focus on this one topic. A
57
58
59
60

1
2
3 good proportion of the journals cater for articles addressing many of the knowledge groups,
4 thus taking a generalist stance, while other journals can be recognised as more specialist in
5 nature, e.g. those in the Q&P group. Pannirselvam et al. (1999) in their analysis identified
6 specific journals that addressed many of their 17 knowledge categories (IJOPM – 17, IJPR –
7 15, JOM – 14, etc.)
8
9
10

11
12
13 ***Finding 2: The network has a generalist core of journals and a specialist periphery***
14

15 Such generalist journals described above tend to be positioned at the centre of the network
16 within the central communities. At the centre of the OM field's map in Figure 3 lie two
17 adjacent but separated communities (C&P and OP&S) that, although different in mean ABS
18 scores, collectively form what could be identified as the traditional core of the OSCM field.
19 The third community that, along with these other two, form the current core is S&L.
20 Notwithstanding the difference between the journal-directed nature of this study and the
21 article-directed nature of many of the previous studies, connections can be seen between the
22 communities and the knowledge groups, particularly in the more "specialist" of the identified
23 communities. For example, service, quality, performance measurement and supply chain are
24 labels common to both knowledge groups and communities.
25
26
27
28
29
30
31

32
33 ***Finding 3: SCM is a strong, central component of the field***
34

35 Apart from the S&L community forming part of the central core in Figure 3, other aspects of
36 the results reinforce its importance. As indicated earlier, Figures 4a and 4b each contain six
37 journals but portray distinctly different views of the centre of the field's core, with JOM as
38 the only journal common to both views. Although in the MDS (Figure 3) JOM lies close to
39 other high-ranking journals such as IJOPM, IJPR and IJPE that form part of the traditional
40 core (as in Figure 4a), our analysis places JOM within the S&L group because of the multiple
41 interlocks between JOM and S&L journals (Figure 4b). This inclusion of the field's strongest
42 journal, in terms of ABS scores, in the S&L group emphasizes the group's importance. While
43 Figure 4a considers the number of connections (i.e. interlocks) between journals irrespective
44 of the number of members shared between the journal pairs, Figure 4b takes account of the
45 number of academics involved in the connection (i.e. multiple interlocks). The analysis
46 shows that S&L is a formidable group when we consider particularly the number of over-
47 overlapping EAB members within a journal interlock. Leaving aside IJOPM, journals from
48 outside of the S&L community do not have this extent of overlapping membership. Figure 5
49 reinforces this view of S&L as a significant group. The strength and coherence of the S&L
50
51
52
53
54
55
56
57
58
59
60

1
2
3 community raises a number of questions. These include: why do S&L journals cohere so
4 strongly, and is this coherence the result of a deliberate strategy on the part of those charged
5 with journal governance or an emergent feature?
6
7

8 SCM as a topic has increased so dramatically that it now comes out as either the top
9 (Taylor and Taylor, 2009; Walker et al., 2015) or one of the top (Behara et al., 2014)
10 knowledge categories in studies of the contents of OSCM journal papers. Could it be that this
11 SCM expansion in recent times has created excess demand for EAB members compared to
12 other communities? An expansion of the area accompanied by the setting up of new journals
13 could create new demand. Although the mean age for the S&L community journals lies at
14 approximately the mean age for all communities in the OM field (28.2 years vs. 27.2); the
15 S&L community does contain a number of more recently-established journals. Recent
16 expansion of board sizes of the S&L journals could have created excess pressure for more
17 board members. The S&L community has the largest mean board size (83.6) compared to
18 other communities (the overall mean is 50); a feature that is influenced by the community
19 including two journals (JOM and JBL) with large boards (177 and 156 respectively).
20
21
22
23
24
25
26
27

28 However, increased demand per se does not lead to the higher level of interlocks; it
29 needs to be coupled with scarcity of supply that leads to increased use of individuals who
30 already have board memberships with other journals. If there were scarcity of supply then
31 one might expect that the USA affiliation would be tempered by bringing in academics from
32 outside this milieu – this does not seem to be the case. The S&L community has the highest
33 proportion of members drawn from US-affiliated organisations and from business schools.
34 Interestingly despite the SCM paradigm emphasising globalisation, the S&L community has
35 strong affinities to one part of the globe, i.e. the US.
36
37
38
39
40

41 Clearly the mechanism by which this strongly-connected SCM-related group appears to
42 challenge the traditional core is not apparent but is open to speculation. One could argue that
43 what we are seeing is a specific group, primarily drawn from US business schools, promoting
44 the interests of a particular intellectual endeavour (SCM) that is (reasonably) novel, popular
45 and challenges the more established order within OSCM. No doubt a mixture of deliberate
46 and unconscious actions by the involved proponents fuel the apparently increasing
47 ascendancy of SCM in the intellectual structure. For example, journal editors looking to
48 strengthen their journal in an expanding area of knowledge invite EAB members from
49 journals working in a similar intellectual area. As indicated earlier this agrees with the
50 concept of homophily drawn from Social Network Theory where social actors prefer to link
51 up with other actors that are similar to themselves.
52
53
54
55
56
57
58
59
60

1
2
3 What may be happening in the OSCM field is a paradigmatic shift with SCM
4 supplanting the prior institutionally-focused traditional OM view. If this is so then it will be
5 occurring at both intellectual and social levels, and could be revealed through a longitudinal
6 analysis. A Kuhnian view (Kuhn, 1996) is that paradigm shifts are neither good nor bad –
7 they just are. Commentators within management have written about paradigm change, e.g.
8 Pfeffer (1993) has argued for a strong, single paradigm while others have argued for a
9 plurality of theoretical approaches (Van de Ven, 1989)(Fabian, 2000). OSCM commentators
10 have discussed changes in topics, theories and paradigms e.g. (Walker et al., 2014; Walker et
11 al., 2015). Such changes will influence the composition of EABs, as indicated above in the
12 discussion of the impact of the growth in SCM.
13
14
15
16
17
18
19

20 Presumably someone in the OSCM field, lying outside of the SCM area, might feel
21 threatened by such a paradigm change. Some academics might see SCM as an emerging
22 component of OM. However, this perspective is not uncontested. If we examine writing
23 within the SCM journals then we see that those authors affiliated to the supply chain area can,
24 and do, take a different position. Frankel et al. (2008) and Mentzer et al. (2008) work from
25 the basis that SCM lies outside of OM, and other functions, and serves to integrate these other
26 functions. Mentzer et al. specifically write about the “turf wars” over who owns, or doesn’t
27 own, SCM. However, given the formidability of the SCM grouping we may need to ask in
28 future whether SCM owns OM.
29
30
31
32
33
34
35

36 ***Finding 4: Demographic diversity is an issue for the field***

37 *Gender*

38
39
40 For AACSB business schools female representation in all academic staff is 29.9% while the
41 value for full professors alone is 19% (Flynn et al., 2015). The AACSB gives the female
42 proportion for the Production/ Operations field as 19.3% for all ranks and 12.3% for full
43 professors. Comprising 3.6% of all business school academic staff (AACSB, 2013), this field
44 is the smallest of the main fields listed by the AACSB and is also the main field with the
45 worst gender imbalance. The female proportion of 11.6% for the study data set is
46 significantly lower (Chi = 46.2, p = .000, df = 1) than the AACSB figure of 19.3 % for the
47 overall field suggesting that gender discrimination exists in the appointment of EABs. In the
48 high status position of editor-in-chief, the female proportion at 6.1% is even lower than the
49 11.6% of the overall EAB data set.
50
51
52
53
54
55
56
57

58 If one were to argue that EAB membership is associated with seniority and the
59
60

1
2
3 proportions of females were improving at lower levels of the profession, then the above
4 difference in proportions between status levels might reflect poorer gender representation in
5 the past. However EAB memberships are not restricted to the rank of full professor, and are
6 often seen more as an award of merit achieved irrespective of rank. The correlation between
7 gender and rank is also evident in the AACSB data where female proportion declines with
8 rank. This correlation is usually interpreted as evidence of discrimination rather than
9 dynamic changes in female proportions. Even if the correlation was evidence of such
10 dynamics, the actual female proportions are still worrying low.

11
12
13
14
15
16 The AACSB data is a relevant comparator given the dominance of affiliations to US
17 organisations in the study data set. However, affiliation to US organisations does not, of
18 itself, mean that the individuals sampled have US nationality since US organisations attract
19 individuals to work in them from across the globe. Notwithstanding this point, the study
20 provides evidence of gender imbalance. Overall the results point to poor gender diversity
21 specifically in journal governance and more generally in the OSCM field. We believe OSCM
22 academics should be concerned about this.

23
24
25
26
27
28 In Table 4 the male percentage is negatively correlated with Business School affiliation.
29 This suggests that OSCM academics located in non-Business faculties, such as Engineering,
30 are more likely to have an even higher proportion of males. This points to one of the
31 beneficial aspects of the growth in the SCM area, namely that out of all the communities,
32 S&L has the highest business school and female involvement.

33 34 35 36 37 38 *Geographic location*

39
40 The domination of the OSCM field by academics affiliated to US institutions seems to reflect
41 the situation in management and business generally (Burgess and Shaw, 2010). This reflects
42 the US position in higher education generally. However, a broader source of domination
43 extends outside of the US to UK and other English-speaking countries. Further to this, the
44 importance of European countries can be seen in Table 6 which also shows that there could
45 well be connections to the location of the society/ publisher responsible for the journal. A
46 comparison of the two traditional core elements (C&P and OP&S) with the more recent
47 element of S&L shows that S&L is more associated with US-based academics than the other
48 traditional two.

49
50 A further issue is that only one individual out of the top ten with multiple EAB
51 memberships (Table 9) comes from the top ten institutions with the highest numbers of EABs
52 (Table 7). This suggests that if multiple EAB memberships is taken as evidence of individual
53
54
55
56
57
58
59
60

1
2
3 achievement then high-performing individuals do not need to be, and are not, located in the
4 highest-performing organisations as measured by volume of involvement in EABs. This
5 suggests that geographic location is more important than status of the individual's institution
6 in securing EAB membership.
7
8
9

10 11 *Business school affiliation*

12 Just as the OSCM communities form their wider field, the OSCM field is part of a wider
13 grouping of management and business fields that are particularly influenced by the business
14 school context. Business schools are the dominant locations for business and management
15 subjects across the globe and their size and influence within universities has grown over
16 recent decades. As mentioned earlier, the traditional OM subject grew out of Production and
17 Factory Management and many OM-related academics are still located within such as
18 engineering faculties today with 51% of EAB members located outside of business schools.
19 The traditional elements of the field's core, C&P and OP&S, have 27.3% and 48.8%
20 respectively of EAB members drawn from business schools while S&L has 81.8%. This
21 indicates that the phenomenon of SCM is strongly-rooted in business schools.

31 **Conclusion**

32 This final section comments on the study contribution, implications, limitations and
33 opportunities for further study. The study's aim was to contribute to better understanding of
34 how the OSCM academic field is comprised of various communities by addressing the
35 research question: how do the interlocking EABs of OSCM journals map out the field's
36 diverse academic communities and how demographically diverse is the field and its
37 communities?
38
39
40
41
42
43
44

45 *Contribution*

46 The study is novel by virtue of applying SNA to EAB data, and in its application to a unified
47 field of operations and supply chain management (OSCM). No prior studies of this type have
48 been carried out for either of the two areas of OM or SCM. The study has identified journal
49 groupings that mark out linked, but separable, academic communities within OSCM.
50 Deducing communities from social connections for web-based EAB data may elicit scrutiny
51 because of its novelty; however we have shown it to be a suitable technique to add to other
52 approaches to mapping a field's intellectual structure. By collecting data from the web we
53
54
55
56
57
58
59
60

1
2
3 were able to cross-check data speedily thus enabling the study to draw from a quality data set
4 which runs counter to the view that web sources can be of suspect value.
5

6 Our study maps out a network with a generalist core and a more specialised periphery.
7 We identify what appears to be a particularly influential and burgeoning community of SCM
8 academics that, together with two other communities representing traditional OM interests,
9 form the core of the field. We highlight how the SCM community differs from other
10 communities comprising the OSCM field, in particular by its high coherence, more
11 favourable gender balance and its high affiliation to business schools.
12
13

14 The study demonstrates the dominance of males in EABs and the influence of
15 affiliation to USA-located institutions and to business schools. The study shows that the
16 gender imbalance in EABs is poorer than that in the general population of OSCM academics,
17 thus providing prima facie evidence of discrimination.
18
19
20
21
22
23

24 25 26 *Implications*

27 By applying SNA to EABs we have added a new method of taking stock of the field to the
28 researcher's armoury – one that uses a social rather than a knowledge focus. With the
29 increase in research reflexivity, such methods and related study outputs will increase in value
30 for researchers. This study has provided a benchmark for the OSCM field that can be
31 compared with future studies and has thus enabled longitudinal study of the field's social
32 dynamics. At a more down-to-earth level the study's allocation of journals to communities
33 can be used by researchers to help target where to submit their papers. For example, if a
34 paper is not accepted by a particular journal then the researcher can look to the other journals
35 in the community as suitably similar targets.
36
37

38 The study provides evidence of the lack of diversity within the OSCM field by
39 showing how low female representation and US domination is embedded within the field's
40 journal governance structures. While the influence of S&L appears to bring with it an
41 improved female representation compared to other parts of the OSCM field, this
42 representation is still at a low level, and conversely comes at the cost of increased influence
43 of US business schools. The analysis throws up a challenge for the field to grapple with –
44 how can OSCM create a more equitable and representative position in the field's journal
45 governance and in the field itself?
46
47
48
49
50
51
52
53
54

55 The existing publishers of OSCM journals who are located in the US, UK and other
56 European countries will no doubt know already of the powerful stake they have in the field.
57
58
59
60

1
2
3 However publishers from those countries not already represented could well be attracted to
4 compete in the field. Leaving such a possibility aside, current publishers might wish to
5 consider what influence they might bring to bear to expand representation. Clearly looking to
6 appoint female editor-in-chiefs could have a positive impact on EAB gender balance
7 (Mauleón et al., 2013) and looking for candidates from outside of the US and UK could well
8 be useful. However editor-in-chiefs and other members of the editorial team might also
9 review their rules and routines for their journal governance. For example they could take
10 action by introducing, if they do not do so already, audits of their EAB demographics, EAB
11 appointment criterion that are transparent and fit for purpose, and gender-blind appointments.
12 Of course there is a limit to what they can do if the membership of the OSCM field continues
13 to be demographically imbalanced. Presumably this is where business school deans and
14 appointment committees have a role to play in trying to encourage a more demographically-
15 balanced workforce. However, the popularity of OSCM and its attractiveness to potential
16 entrants to the academic profession is a constraining factor. In the past OSCM has gone
17 through periods when its perceived value has been lower than at present – which is not that
18 particularly high; but the advent of such as lean thinking has helped to renew interest within
19 academia and business. The upsurge in SCM highlighted here has also increased the interest
20 of potential entrants in a key contributor to today's global economy. The issue of popularity
21 and attractiveness of OSCM raises questions about its standing versus other disciplines and
22 fields within business schools. OSCM, as pointed out earlier, has the smallest proportion of
23 staff of all the main fields in business schools and has the worst gender imbalance.
24 Presumably these two factors are linked?

25
26
27
28
29
30
31
32
33
34
35
36
37
38
39
40 Finally in terms of implications we comment as follows. Given the study findings on
41 gender imbalance, geographic location and business school location we suggest OSCM
42 academics might reflect on their professional circumstances. Consider how a female
43 university academic based outside of the dominant group of English-speaking countries, and
44 who does not specialise in SCM, e.g. they specialise in quality, might feel after reading the
45 results of this study.
46
47
48
49
50

51 *Limitations*

52
53 The set of OSCM journals used in the study is a comprehensive one, but does not include
54 every journal that is OM- or SCM-related. Since the study was completed a more extensive
55 list has been published in the updated (2015) version of the ABS journal quality rankings.
56 Using the well-regarded ABS list does mean that all the key OSCM journals are included in
57
58
59
60

our study, however it does have the drawback that the ABS scores may be criticised as favouring European-related journals. The study focuses on those journals classed as OM and SCM. It does not include journals in associated and reference disciplines where OM academics also publish, e.g. Management Science and other OR/MS journals; nor does it cover general management journals where they also publish. A wider study could be carried out that included these other journal types, but this would be a more substantial, future endeavour that would cast light on the connections that the OSCM communities have to communities in adjacent fields. This study focuses on journals and thus excludes books and other artefacts such as conference proceedings. However, this focus reflects that journal articles are the main knowledge products examined when evaluating management and business fields. While we may be unsure about why appointments are made to EABs and debate what the journal interconnections signify, their existence is undeniably a substantive social phenomenon that tells us something about the OSCM academic community.

Further study

Given that this study verifies a novel approach by applying it to the OSCM area, its use leads to the potential to deploy it in further studies. For example, a study could be carried out to compare the network structure and demographics of OSCM against similar fields. Whereas this study focuses on communities within OSCM, extending the analysis of EABs to reference and adjacent disciplines would give an informative picture of how OSCM is embedded within the wider academic terrain. A follow-up longitudinal study would illuminate any changes in the communities over time, e.g. the extent to which the S&L community might grow even more influential in future. This research studies at an aggregate level the results of EAB appointments; this leaves open opportunities to study the detail of why EAB appointments are made.

Table 1 Example studies relating to the structure and evolution of the OM field

<i>Author (date)</i>	<i>Approach/ method</i>	<i>Main points</i>
Buffa (1980)	Conceptual	Identified key topics emerging over time, e.g. OM emerges distinct from MS/OR
Chase (1980)	Survey of articles grouped by authors (1977-79)	Applied 2x2 matrix of Research emphasis vs. Research orientation
Miller et al. (1981)	Delphi process with six stage categorisation and review	Four main topic areas
Mabert, (1982)	Article review and categorisation of topics	Categorised research or application focus by particular problem decision area
Voss (1984)	A two-day workshop attended by 50 + P/OM researchers	Field categorised into 10 areas
Amoako-Gyampah and Meredith, (1989)	Survey of topics in six OM research journals (1982-1987)	Categorised field into knowledge areas. Main area - operations control.
Meredith and Amoako-Gyampah, (1990)	Survey of topics of interest for 151 US OM academics	Categorised field into knowledge area
Neely (1993)	IJOPM articles categorised by 2 x 2 framework.	Micro/ macro research focus x research emphasis (hard/ soft)
Vokurka (1996)	Citation analysis to assess most cited of four key journals	Top 10 most cited journals identified
Scudder and Hill (1998)	Survey and classification of 477 OM papers by author perception of OM focus	Papers classified by knowledge categories and research methods
Pannirselvan et al., (1999)	Content analysis of articles in 7 journals 1992-97 by 17 types	Strategy and quality more prominent. Topics emerging include NPD and SCM
Pilkington and Liston-Heyes (1999)	Citation and co-citation study of IJOPM 1994-97	Topics include manuf. strategy, Japan, perf. measurement and best practice
Barman et al. (2001)	Survey of how POMS academics rank 21 journals	Little change in field since previous study (Barman et al., 1991)

1			
2	Vastag and Montabon (2002)	Analysis of rating & referencing practices for 28 journals	Three categories of journals: OM, OR and Management and four “outliers”
3			
4	Chopra et al. (2004)	Historical analysis	OM focus on tactical issues changing over time to strategic, SCM increasing
5			
6			
7	Pilkington and Fitzgerald (2006)	Citation & co-citation analyses of IJOPM 1994-2003	Manuf. Strategy incl. RBV, Perf. Measurement, Lean, SCM, etc.
8			
9			
10	Sprague (2007)	Historical narrative	Editorial for special issue on evolution of the field of operations management
11			
12	Craighead and Meredith (2008)	Content analysis of MS, DS, POM, JOM, IJOPM 1995-2003	OM becoming more interpretive. Jnls emerging to cover service & SCM
13			
14	Pilkington and Meredith (2009)	Citation analysis of articles in JOM, IJOPM & POM 1980-2006	Key knowledge groups: manuf. strat. , quality, process design, etc. But strat. & tactical topics losing out to SC & quality
15			
16	Kulkarni et al. (2011)	Latent Semantic Analysis of 30 years of IJOPM articles	Identified major topics and methods
17			
18			
19	Petersen et al. (2011)	Meta-analysis of journal ranking & citation analysis of IJOPM, JOM & POM 1999-2005	OR and OM separating, SCM more prominent
20			
21			
22	Singhal and Singhal (2012)	Historical view of various paradigm shifts occurring in OM	SCM as latest paradigm to emerge
23			
24			
25	Simpson et al. (2015)	Thoughts of a large group of scholars in the field of operations and supply chain management (O/SCM) regarding current and future issues facing profession	Need for: greater innovation and creativity in O/SCM research, handling complexity and “big data,” collaborating and working in other research domains, confronting new technology, and communicating value of research
26			
27			
28			
29	Shiau et al. (2015)	Co-citation study of papers in Web of science containing “supply chain management”	Identified four core research areas: sustainability, strategic competition, value of information, and development of SCM
30			
31			
32	Walker et al. (2015)	Content analysis of papers in JOM, POM and IJOPM 1980-2013 to identify theories and topics	Claims while previous research looks at topics this is the first paper to look at theoretical trends in OM
